In their zeal to put an end to the many evils which undoubtedly arise from the presence of intoxicating drink in workhouses, some boards of guardians have hastily adopted measures of doubtful, and even of illegal, procedure. One board, for example, when a new medical officer was about to be appointed, induced him to enter into a contract to supply all the stimulants he should deem it necessary to prescribe, for the sum of £30 per annum. The Local Government Board at once wisely declined to approve of this extraordinary compact, and the resolution of the guardians was therefore rescinded. It would indeed be an anomaly if, at the very time when the medical profession is becoming more alive to its dignity, and gradually severing, as far as practicable, profit by the sale of drugs from legitimate fees for medical advice, Government medical officers were to contract to furnish the medicines which intoxicate. In the interests of the pauper it is desirable that his medical attendant should have no pecuniary interest in the quality or the quantity of the remedies employed. The practice of no medical man ought to be exposed to the risk of being even unconsciously influenced by considerations of personal emolument from the medicines taken.

Again, another board of guardians went so far as to pass the following resolution:—"That the large amount of alcoholic stimulants supplied for the use of the sick inmates in this union is unwise; that it is unjust to the ratepayers; and that, subject to the approval of the Local Government Board, such stimulants shall be discontinued for the future." The Local Government Board, I need hardly say, withheld their approval. One official, and one alone, is responsible for the medical treatment of the patients. That official is the medical officer. So soon as his hands are tied by the prohibition of any of the medicinal agents he deems needful, just so soon will his responsibility for the treatment of his patients cease. There can be no divided responsibility. So long as the medical officer has sole direction of the medical care of the sick, just so long will the pauper have fair play. The moment the doctor's resources are crippled, the responsibility is shared between him and the party curbing him, and between the two stools the pauper cannot fail to fall to the ground. Hence the Local Government Board did right in declining to limit the medical officer's choice of remedial agents.

A strong effort has been made in different parts of Ireland to have ordinary alcoholic drinks included under the denomination of drugs, to be supplied to the patients by the dispenser like any other therapeutic remedy. Were the liquor always given as part of a not too pleasant and fascinating medicinal mixture, this might be a benefit to the sick poor, inasmuch as they would not know they were getting an intoxicant, and thus they would not be so liable to be confirmed in their strong prejudice in favour of alcohol as a beverage. But, unfortunately, this was not the aim of the agitation, the object of which was confessedly to save the rates by securing, if possible, the cost from the State under the head of drugs. At present, the whole expense for stimulants is born by the locality. I fear that, if this agitation had been successful, the consumption of stimulating liquor in our workhouses would have been greater than ever.

The Local Government Board have declined, as indeed was to have been expected, to comply with this request to sanction an arrangement by which all stimulants used in workhouse hospitals might be regarded as drugs, be placed in charge of the dispenser for administration under the orders of the medical officers, and be charged like other

medicines on the Parliamentary grant. The issue of stimulants, the Local Government Board stated in their reply, was already restricted to cases in which the medical officer might give directions in writing for their use in individual cases, and no part of the cost of stimulants such as wines and spirits could be defrayed out of the Parliamentary grant for medical purposes.

The public, in many localities, are taking great interest in the consideration of this question of workhouse stimulants, and it is useless, if indeed it were right, to attempt to stifle the controversy. The wisest and most prudent course is to direct the popular agitation into such a channel as will effect the greatest amount of good. Now that I have pointed out what all interested in this subject ought to avoid, I am bound to indicate what seems to me to be the proper method of procedure. First, recognise the medical officer as the sole arbiter of what medicines his patients are to receive. Starting with this as an axiom, no right thinking person can possibly object to either the guardians or the general public using every courteous means of presenting to the medical officer a fair statement of the moral risks inseparable from the indiscriminate and profuse prescription of alcoholic liquors, and of the experience of an increasing number of his colleagues in the Poor-law service, who have made a genuine trial of either the complete exclusion of these drinks or a very great diminution of their consumption. No intelligent and fair-minded member of the medical profession can take offence at any respectful request for his candid perusal of scientific and thoughtful treatises on the influence of alcoholic drink on the individual and on society at large. Guardians may do much and yet duly respect the office and dignity of their medical officer. I am acquainted with parishes where a respectful and polite request from the board to the medical officer to give the matter his best consideration in the interests of the poor and of the general community, has resulted in a thorough study of the question on his part, and the consequent institution of a legitimate and successful experiment.

(To be continued.)

## INJURY OF THE HEAD: ESCAPE OF MEDULLARY SUBSTANCE AND ARACHNOID FLUID.

By ALLEN EDMOND DOUGLAS, M.D.,

THE following remarkable case shows how well a child may get over a very serious injury, and I doubt very much whether an adult would have recovered so well under similar circumstances.

June 1, 1880, 7.30 p.m.—Mr. L. when playing with his child, aged six months, slipped on a piece of bread and butter, and in trying to recover his balance the infant fell out of his arms down stairs, about seven steps, and hit its head against the corner of a chair, causing an irregularly incised wound, about two inches long, in the centre of the forehead. I was in attendance a few minutes after the accident, and found the child's face covered with blood, and a welt, nearly as thick as the little finger, of medullary substance corresponding to the size of the wound protruding on the forehead. There was also a small wound of the skin at the lower end, and a bloody tumour over right parietal bone. Except these there were no other alarming symptoms. No loss of consciousness; no convulsions; no vomiting; pupils equal; pulse regular, though of course excited. I should also have mentioned that there was a profuse flow of arachnoid fluid from the wound. I could not bring the edges of the wound very close together with adhesive plaister as the brain substance came welling up on the slightest pressure, so I merely applied a cold lotion, and gave *hyd. submur.*, *pulv. Jacob* and *cret. co. c.* opio.

10.30 p.m.—Vomited once after the powder, and is now sleeping calmly.

2nd, 10.30 a.m.—Slept well all night, and takes the breast eagerly; bowels moved once, no symptoms of any kind. The dressing has come off, showing the brain pul-

zing through the gaping wound, with a free discharge of arachnoid fluid. I closed the wound with two simple silk sutures, but in doing so more cerebral substance mixed with venous blood came away. Cold lotion to be continued, as well as the hyd. submur.

5.20 p.m.—Sleeping quietly. Mother says it was "quite happy all day, and crowing as usual." Wound looks well, but a free discharge of fluid still. At this time my friend, Dr. Eustace, saw the case with me, and agreed that nothing more should be done at present.

3rd.—Sleeping quietly, but bright and happy when awake. Wound looks healthy, but still oozing; stools green; drinks well; gave the mother a good dose of castor oil.

4th.—Good night; no symptoms; no oozing.

5th.—good night; no symptoms; gave bromid kali, ʒss, aq. ʒij., a teaspoonful three times a day.

6th.—Was sick after the bromide yesterday, and is to take only half the quantity. Wound healing.

4.30 p.m.—Omit the bromide, and begin the hyd. submur again.

7th.—No change; apply carbolised oil to forehead, which is itching.

8th.—Remove sutures; a thick scab covers the wound.

9th.—Does not seem quite so well, but nothing wrong.

10th.—Wound granulating, and bloody tumour subsiding.

11th.—As the swelling has subsided the brain can be seen and felt pulsating through the crack in frontal bone. A slight oozing of fluid in one spot where the scab has come off.

13th.—No change.

14th.—Took away part of one of the sutures which happened to be left behind. No other change.

16th.—Lower wound healed, but there appears to be a fistulous opening at upper end of long wound through which the arachnoid fluid pours in a constant oozing.

18th.—Cauterised the fistula.

21st.—No oozing since cauterisation. To take Parrish's syrup.

22nd.—Free discharge of fluid; I applied a piece of dry lint to the fistula, and covered it with another piece wet with flexible collodion.

29th.—Scab has come off, and no oozing since.

July 22nd.—Patient as well as ever, had his portrait taken to-day, which I enclose.

From first to last the little patient never lost an hour's sleep or refused its drink!

patient consulted many physicians, and followed all kinds of treatment, but no permanent benefit resulted.

The general health, however, suffered little. She kept her appetite and strength; the menses remained regular. Never any hæmoptysis; sometimes sweating, but only after violent coughing; no emaciation; no diarrhoea.

On admission, condition as follows:—Face flushed, slightly puffy; no œdema of legs; marked dyspnoea, rendering walking and active work impossible; cough frequent, spasmodic, with suffocative attacks during night; abundant mucous and muco-purulent expectoration; chest resonance exaggerated, almost tympanitic, especially at base; respiration emphysematous, vesicular murmur weakened; sibilant and moist râles, accompanied by rhonchus, very numerous in the whole extent of the chest of both sides; heart normal; no evening pyrexia; pulse regular, strong, moderate tension; no albumen in the urine; tongue healthy; appetite maintained; digestive functions normal; frequent and profuse night sweats, especially after suffocative attacks.

From these symptoms there was diagnosed generalised chronic bronchitis, non-tubercular, with consecutive pulmonary emphysema.

In two or three weeks treatment gave little result. There was at first apparently slight improvement; but soon the cough and dyspnoea reappeared with greater intensity. The least change of weather, especially to damp, brought on extreme suffocative attacks, which sometimes lasted many hours, causing profuse sweating, and leaving behind marked cyanosis of the face.

On October 30th the chest was again examined. Comparative percussion of the two apices revealed slight diminution of elasticity in the eighth supra- and infra-spinous fossae. At the same place there was hardness of breathing, with prolonged sibilus; for the rest of the extent, sonorous and subcrepitan râles mixed. Respiration ample, prolonged, resembling that of an asthmatic. General state remains good.

During November things remained in *statu quo*, or the functional troubles seemed aggravated. The patient, a prey to continual oppression, was incapable of the least effort, and obliged to maintain the sitting position in bed. Absolute insomnia, from frequent cough and suffocation. Expectoration mucous or muco-purulent, aerated, not viscous—quantity, from 200 to 500 grammes daily. Iodide of potassium, ether, hypodermic injection of morphia, and chloral used without result.

On November 27 it was decided to try punctiform cauterisation of the thoracic walls, with the thermo-cantery. It was performed at once, and a large number of superficial spots were scattered over the whole extent of the dorsal region.

The next day there was marked decrease of all symptoms. The patient had slept better. Cough and dyspnoea less severe. On auscultation much fewer moist râles; sibilus persistent.

On November 30th the cantery again applied, followed by still more marked improvement. Expectoration much less. Patient could take the horizontal position. No more suffocative attacks.

December 3rd.—Third application, after which convalescence progressed regularly; cough almost entirely ceased; dyspnoea insignificant. The patient sits up all day, walks from room to room, and goes upstairs without fatigue. She asked for all medicines to be stopped. Auscultation shows no râles; vesicular murmur, rather feeble, heard everywhere; emphysematous resonance much diminished.

On December 7th, 15th, and 21st the cantery was applied again. This was in order to assure the cure.

On December 29th the patient, entirely recovered, claimed her discharge. A final examination showed the resonance of the chest everywhere normal, except a slight want of elasticity at the right apex, due apparently to a little chronic pneumonia; no tympanitic sound at either base; sound normal and equal on both sides. Breathing slightly rough in the right supra-spinous fossa, is everywhere else of perfect amount and purity; not the least râle, either dry or moist; respiratory rhythm regular and normal. No cough; no dyspnoea; expectoration nil. The general state is as good as possible, and the patient has recovered all the vigour and activity of her age.

## Clinical Records.

### HOPITAL DE LA PITIE, PARIS.

Under the Care of PROFESSOR PETER.

*Case of Chronic Bronchitis for Three Years unrelieved by usual means; Rapid Cure by Punctiform Cauterisation of the Walls of the Thorax.*

Reported by Dr. H. BARTH.

B. B., et. 20, seamstress, admitted October 6th, 1880, under Professor Peter. Well developed and apparently robust, she had no hereditary antecedents worthy of note. Her family seemed free from tubercle, rheumatism, and every other diathesis.

She had had good health, and no illness before the present. Commenced to menstruate at 14; continued regular and in good health till she was 17.

At this time, the autumn of 1877, she took cold, which caused feverishness and all the symptoms of acute bronchitis. She was not taken good care of. After resting a few days she resumed her work, in spite of persistent cough and marked oppression. Gradually the cough increased in frequency and intensity; expectoration slight at first, became more abundant and muco-purulent. There was habitual dyspnoea, with occasional suffocative attacks. In three years the symptoms persisted and increased. The

## Transactions of Societies.

CLINICAL SOCIETY OF LONDON.  
FRIDAY, MARCH 25.

The President, JOSEPH LISTER, D.O.L., F.R.S., in the chair.

Mr. J. R. A. DOUGLAS, of Hounslow, on cases of  
VARIX OPERATED ON WITH AN INSTRUMENT INVENTED BY  
HIM, CALLED A VEIN-BROOCH,

which produces flat pressure on varicose veins and varicocele, by means of a horn spatula, or made of horn and steel, with a grooved needle rivetted at the eye-end, and fastening at the point, after passing under the vein, by a catch like a brooch or safety pin, giving very little pain, and (unlike the old torsion of wire or silk ligature) producing no constitutional disturbance, but obliterating the vein with certainty, and without subcutaneous division. He referred to another extremely simple instrument invented by A. Baird Douglas, who was taken prisoner by Russians at the Battle of Telis, outside Plevna. A flat-pointed steel pin passed to the head through a disc of india-rubber, then through the edges of a wound, and then through another disc of rubber, holding the edges of a wound perfectly and tightly together without other ligature. The extreme tenacity of the rubber prevents slipping, and can be passed on wire without moving in cases of ruptured perineum, vesico-vaginal fistula, &c., &c. Wounds heal by first intention, as the soft rubber prevents the pin ulcerating out, as wire and silk ligatures do with a knot. These instruments are all made by Messrs. Maw and Thompson, Aldersgate Street, London. Messrs. Douglas claim for their inventions—simplicity; easy application and easy removal; re-application in a moment; little pain or constitutional disturbance; assured obliteration of vein; cuticle always visible when horn only is used; the most unskilled can control varicose hæmorrhage; great comfort to those fearing the frightful bleedings from varicose veins by the possession of the vein-brooch. The Director-General also, Dr. Longmore, of Netley, and other surgeons who have seen these instruments fully appreciate their simple use. A large number of Mr. A. Baird Douglas's Red-Cross pins were sent early in February last to the Transvaal by order of the Director-General, Sir W. Muir, who himself invented an elastic band to prevent varix in soldiers.

*Cases.*—Police-constable George Warren, of Hounslow, æt. 43 years, thirteen years' service, was ordered by the chief surgeon, when seen at Scotland Yard, to be operated on by me. Had suffered great weakness and cramping pains of right leg, which unfitted him for duty. I found an enormously distended vein of thigh, with engorged veins below knee. I applied two brooches under thigh vein, and divided two days after subcutaneously. Within three weeks the man was fit for duty, and had no bad symptoms, nor has he suffered since, although frequently up to his knees in snow of a night. He states he has not had such comfort for years.—Police-constable William Dolton, æt. 38 years, 13 years' service in police, had diffused varix below knee for six years; had ulcerated leg twice; had been six months on sick list for same. The chief surgeon ordered the operation. The saphena vein inside and under knee was very large and full; below it a large bunch of varicose veins, and an open ulcer just above ankle. Passed one brooch under big vein; did not divide. The ulcer healed during the time he was on his bed, and he soon resumed duty quite well. This man has been much exposed during the late inclement weather. The vein being deep, the patient being stout, it was well grasped, not to implicate much skin; there is no mark of operation.—Michael Harrigan, a powerful bricklayer, living near Sloane Street, Brompton, presented himself as a militia recruit at the assembly station, London. I found he had a large varicose saphena vein inside and below knee; there was also a bunch below that, and he was rejected in consequence. I offered to operate on him at his own house, and did so with one brooch, desiring him to keep quiet, when he would be fit for service. Two days after I went to see him, but he was not at home, and I did not catch him until the tenth day, when he came home as I was waiting, he having a black eye. I removed the brooch, which he had been constantly walking about with. The varix had disappeared. This evidences the little pain and irritation caused by this simple operation. He was accepted for the militia thirteen

days after the operation.—Mr. John ———, of Hounslow, æt. 40, a private patient was operated on this month. Had varicocele six years, with weakness and cramp, and cold extremities. There was an ulcer above ankle, engorged vein under knee, and large bunch below. Had the saphena vein well grasped by an assistant, Henry Bullock, and passed the grooved needle of a horn brooch behind it, the rubber pad pressing tightly on the vein. The operation did not take a minute. The brooch was removed the fifth day, and the varix had disappeared. The ulcer is now quite healed. There was no constitutional or local disturbance.—The last case I shall trouble you with is one of varicocele, in Private Primrose, a soldier of the 18th Hussars, whom I found left by his regiment in the Hounslow station hospital, having that day been permanently invalided by Surgeon-general Holton, who has charge of the home district, and came from Woolwich to invalid patients. On my asking if I might operate, he was kind enough to say I might do so as often as I pleased at the station hospital, with the consent of the surgeon in charge. Primrose had a long pendulous varicocele of left side, quite preventing him from riding, and unfitting him for service dismantled. Henry Bullock grasped the bunch of veins, not to implicate too much scrotum, and, in the presence of the two army surgeons, I passed two horn and spring brooches behind veins, as I thought of dividing, but did not do so. On the seventh day I removed one brooch, and the following day Dr. Gunning, the army surgeon in charge, removed the second. Primrose left hospital as soon as his invaliding papers arrived, and so perfectly cured that Dr. Gunning stated he would re-attest him if he was otherwise fit for service had he enlisted again.

Mr. A. P. GOULD said he showed pins similar in form to those described by Mr. Douglas three years ago. They had been used instead of sutures after amputation of the leg. His were much larger, and the clamp consisted of vulcanised rubber. The pin answered admirably, and pressure on the rubber effectually stayed intermediary hæmorrhage which took place.

The PRESIDENT expressed surprise that the brooches were sufficient for the cure of extensive varix in the lower limbs.

Dr. WHIPHAM and Mr. PICK on

A CASE OF EXTIRPATION OF THE LARYNX FOR A GROWTH ORIGINALLY AFFECTING THE LEFT VENTRICULAR BAND AND VOCAL CORD, WHICH SUBSEQUENTLY INVOLVED THE WHOLE LARYNX.

The patient, a commercial traveller, æt. 39, consulted Dr. Whipham on May 27th, 1876, on account of huskiness and a constant desire to "clear the throat," which had come on suddenly and without apparent cause. He had been previously free from all throat affection, and there was no history of syphilis. The man was very nervous, and it was not until June 8th that a view of the larynx was obtained. It was then found that a warty-looking growth, rather larger than a pea, arose from the anterior part of the left ventricular band and vocal cord. After repeated examination and the passage of brushes into the larynx with a view of preparing the patient for operation, his nervousness was so far under control on July 29th that two small portions were removed by evulsion, with great relief to the huskiness. The case was constantly under observation, but no further operative interference was required till March 3rd, 1877, when three pieces of the tumour, (which microscopically presented for the most part the appearance of papilloma, but in which at one or two spots there appeared to be a tendency to the production of epithelial cells) were removed by the forceps. The whole of the warty portion was removed at this time, but the vocal was thickened generally; the voice recovered tone to a great extent. Subsequently, however, it was found necessary to apply the forceps to a recurrence of the growth on several occasions, viz., June 16th, 1877, January 5th, 1878, March 23rd, 1878, April 19th, 1878, December 31st, 1878. Early in 1879 the patient had a severe attack of catarrhal laryngitis, and on June 23rd in that year he complained of having lately suffered from great dyspnoea, with tenderness over the thyroid cartilage, and some external swelling in this situation. He was admitted into St. George's, and in the course of the following six weeks several pieces of the tumour were removed. Again, in October, 1879, a large piece was taken from the larynx. By March, 1880, a great change had occurred in the state of the parts: the growth involved the whole ventricular band and vocal cord; the left ala of the thyroid cartilage

was pushed outwards and was tender, dyspnoea being at times urgent. Towards the end of April the dyspnoea threatened suffocation, and Mr. Pick, after examining the patient, performed tracheotomy, from which the recovery was perfect. During the next six months the disease progressed rapidly, the whole larynx being involved by the middle of October, when a large lobulated mass was felt in the position of the left ala of the thyroid cartilage. In the early part of November, 1880, some hæmorrhage occurred through the tube, and at the end of the year he was re-admitted into hospital with a view to some radical operation; shortly after his re-admission this hæmorrhage recurred to a somewhat alarming extent. After consultation with his colleagues on the previous day, Mr. Pick proceeded to extirpate the larynx. On January 16th, 1881, having introduced a tampon canula, Mr. Pick made an incision two and a-half inches in length in the median line of the neck, and a second incision at right angles to it across the middle of the thyroid cartilage. On reflecting the skin the growth was found to involve the left ala of this cartilage. The thyroid cartilage was then divided vertically in the median line, and the two halves separated, when the whole larynx was found occluded by the growth. The left ala was removed, and subsequently the right also. The cricoid with the remains of the arytenoids were then freed from their attachments and removed, and finally the epiglottis, which was involved in the disease, was cut away. The wound was carefully explored, and all traces of the growth as far as possible were removed. No vessel required ligature. The operation occupied three-quarters of an hour, and the patient was not much exhausted at its close. The wound was plugged with sponges. Slight hæmorrhage occurred after the operation which was arrested by the introduction of an additional sponge. Nutrient enemata were ordered every four hours, and for the first two days the patient's progress was satisfactory. On the third day, however, his temperature rose to 103.2 Fahr., and his skin became dry; his pulse ran up to 142. On the fourth day he complained of severe pain about the ensiform cartilage, and his expression became anxious. Rapid exhaustion set in, and he died on the morning of the fifth day after the operation. At the autopsy right pleurisy and pericarditis, presumably pyæmic, were the chief lesions found. Among the many points of interest in the case the following were brought especially before the notice of the Society:—1st. That for three years the microscopic appearances of the growth were for the most part those of papilloma. 2nd. That the long duration of the disease (four years) was rather in favour of its having been an innocent growth in its earlier stages, although microscopic examination showed that, even at the onset, there was in one or two places a tendency to epithelial proliferation. 3rd. That the above facts and the limitation of the growth to the larynx were favourable to the success of the operation of extirpation. 4th. That if the operation had been undertaken as soon as the malignant aspect of the disease became manifest, success might have been the result. 5th. That the plan of dividing the thyroid cartilage and removing each half separately is preferable to the method adopted by Dr. Foulis of removing the larynx entire, and for these reasons: firstly, that by separation of the ala a good view of the extent of the disease is obtained at an early period of the operation; and, secondly, there appears to be less danger of wounding important structures.

Dr. SIMON, who had been present at the operation, expressed his admiration of the skill with which it was performed. His tampon canula had been depreciated on account of the ill-success which had attended its use in some cases. The accidents had been due to over-inflation of the instrument in all these instances, and he would caution future users of it against the readiness with which such a misadventure might arise. He did not doubt the growth was epitheliomatous at the date of the operation, and he felt that interference to this extent could be justified only after irrefragable proof of a malignant growth had been obtained. Simple papilloma has for its worst result suffocation; and this can be provided against by simple means. Bleeding, however, would indicate malignancy, and when this had been demonstrated, operation should forthwith be resorted to for removal of the involved structures by excision. Excision on any other grounds would be an indefensible proceeding. About the time of Mr. Pick's operation, a case was reported from Berlin, which aptly illustrated this conclusion. Tracheo-

tomy had been performed in a child suffering from papillomatous degeneration of the whole larynx, and repeated subsequently. Thyrotomy was next resorted to; and the growth continuing after it, excision of the larynx was advised by the attending surgeons. Eventually, however, endo-laryngeal operation resulted in complete cure of the case; and the teaching of it was distinctly against extirpating the larynx for simple papillomatous disease. Dr. Simon, however, thoroughly concurred in the need for this measure in the case described in the papers, and was of opinion, with Mr. Pick, that had it been resorted to some months earlier, a more satisfactory ending could have been anticipated.

Mr. PICK explained that he wished excision had been done at the time when tracheotomy was performed—i.e., when he first saw the patient. His idea then was to incise the thyroid in the middle line, and thus investigate the extent of the disease, at the same time removing the left ala of the cartilage, which was then evidently affected.

Mr. W. SPENCER WATSON ON

A CASE OF INTRA-CRANIAL DISEASE, INVOLVING SEVERAL CRANIAL NERVES.

A married woman, æt. 36, who had suffered from miscarriages, and a severe flooding after a confinement, was seized with neuralgic pain of the left side of the face, with loss of sensation in the same side of the face, ptosis, and loss of smell, taste, and hearing of the same side. After the symptoms had persisted seven months, twenty grain doses of iodide of potassium were given three times a day with the effect of rapidly relieving the pain in the parts, and restoring the sense of smell, taste, and hearing, and partially restoring the paralysed upper lid, and the paralysed ocular muscles. There was a relapse after the relief had persisted for more than a month, and the condition of the patient was still unsatisfactory at the last time of seeing her. The amount of iodide of potassium taken in a continuous course of thirty-one days' duration, was between 3½ and 4 ozs.

Dr. BUZZARD said that class of cases was not uncommon in constitutional syphilis. Sometimes, with peripheral affections of the fifth nerve, the portio dura of the same side was involved; the perfectly anæsthetic conjunctiva and ulcerated cornea being their accompanying symptoms. Whether this ulceration was a consequence of trophic nerve disturbance, or consequent on exposure to irritation, remained a physiological problem. Without doubt coincident disease of the fifth nerve and the portio dura resulted in ulcerated cornea; but the case described was an interesting one to physiologists from the fact that, by the existence of ptosis, the eye-ball had been protected from irritation of foreign bodies, and no ulceration of it had taken place, notwithstanding that the fifth nerve had been a long time diseased. In spite of the iodism he would have pushed the pot. iodid., and specific treatment by mercury also.

Dr. WHIPHAM explained that the iodism might be prevented by dilution of the iodide mixture. Even when giving doses amounting to two scruples three times a day, he had been able to avert the symptoms of iodism by freely diluting the medicine, each dose being divided into several portions, and swallowed with much water.

The PRESIDENT thought the marked good produced by the iodide indicated the advantage of pursuing the same treatment further. He was not aware that iodism was avoidable by dilution. Was the drug so beneficial when thus administered? It was well known that large doses will accomplish what meagre ones will not. He would like to see the effect produced by mercury on this case.

Dr. WHIPHAM replied that he was quite convinced the good effect of the iodide was in no sense diminished by dilution.

Dr. DOUGLAS POWELL had been taught the fact that dilution prevented iodism many years ago. His own experience was that the drug was thereby rendered more efficacious.

Dr. RADCLIFFE CROCKER remarked that the addition of strychnia in small quantities to the iodide mixture increased its efficacy. Arsenic also was powerful to remove the skin affection produced.

Mr. WATSON agreed that mercury should be employed in treating the case further. He had tried it, but ceased its continuance on account of the gastric disturbance created. He intended to push it on cessation of the pain,

which had been very severe. He quite coincided in Dr. Buzzard's explanation concerning the cornea. Cases had occurred in his practice, in which healing of the ulcers had been promoted by keeping the lids down by the aid of plaster. It was possible that the trophic nerves were so disturbed as to lead to inflammation internally. Bed-sores commonly occur in persons whose sensation of the parts is not destroyed. Mr. Watson's experience of the dilution of the iodide mixture confirmed that of other observers. He found its efficacy increased also by the addition of a small amount of ammon. carb.

#### SURGICAL SOCIETY OF IRELAND.

A MEETING of the Surgical Society of Ireland was held on Friday evening, Feb. 18, 1881, in the Albert Hall, Royal College of Surgeons. Mr. E. STAMER O'GRADY presided.

Mr. JOLLIFFE TUFNELL, hon. sec., read the minutes of the previous meeting, which were signed.

##### EPITHELIOMA OF THE TONGUE.

Mr. WM. WHEELER exhibited the middle, anterior, and left side of the tongue, which he had removed on the previous Thursday in the City of Dublin Hospital from a man, aged about 53 or 54 years, who had been sent to him by Dr. David Hadden, of Wexford. The drawing, which he also exhibited, illustrated accurately the nature of the disease—epithelioma, and its extent also. The patient states that he did not observe the growth until six weeks ago. The floor of the mouth was quite free. There were not any glands enlarged. In operating Mr. Wheeler said he had divided the cheek for about three inches, and transfixed the tongue well behind the diseased structures with a strong pin, and with the thermocautery (which he exhibited) divided the tongue in front of the pin about half-an-inch behind the disease, and then down the centre, removing the portion now exhibited. The left lingual artery was ligatured, and the cheek quickly brought together with points of suture. During the entire time the patient was under the influence of an anæsthetic. He was now progressing favourably.

Dr. QUINLAN read a communication conveying the details of a case of

##### PARACENTESIS OF THE BLADDER,

which will be found on page 264.

The CHAIRMAN, in inviting discussion on the paper, said there could be no subject in which the surgeon had more interest, as, under the circumstances, there was not time to consult or try temporary measures. He alluded to a similar case of retention of urine, in which he was, himself, with a gentleman present (Mr. Corley) concerned; the patient was an old man, for whose relief tapping was meditated.

Mr. L. ORMSBY said about a year ago he had had occasion to tap the bladder in a man, *æt.* 36, all the usual methods of catheterism having utterly failed. Some were better able than others to get in a catheter; but though he had the advantage of his colleagues, they failed also. The patient was in an anxious and painful position as a man would be with a full bladder. He called in the same manner as Mr. Quinlan's patient did for relief. Accordingly he tapped him through the rectum as a safer operation than tapping over the pubis; and the aspirator being a straight one, he thought it better to use the usual curved trocar and canula. Without much trouble he performed the operation, removing a large quantity of water. Next day he was able to insert a No. 6 catheter. Six years previously, the same patient had been tapped at Folkestone by an English surgeon over the pubis. The case was purely one of spasmodic stricture; and occasionally the patient came to be relieved, but without any necessity to be tapped again. Had he had the aspirator in the first instance, he would have tapped him above the pubis; but he believed it was easier to tap the bladder through the rectum. He did not leave the canula in, and the same evening the patient relieved himself naturally.

The CHAIRMAN suggested that the important question as to whether tapping should be through the rectum or above the pubis, being undecided among surgeons, might be worthy of consideration.

Mr. A. H. CORLEY thought the case the Chairman had at the outset referred to, was one which he attended with him some years ago, a little distance from Dublin. It was analogous to Dr. Quinlan's case; the question being the important one of whether it was justifiable to perform the serious operation of tapping the bladder. Mr. Adams used to say the proudest

epitaph a surgeon could have on his tomb would be, "He never tapped a bladder!" However, the too strict observance of that dictum might lead to placing tombstones over the patients. But Mr. O'Grady's case confirmed Dr. Adams's view. The symptoms were so urgent, the unfortunate man had himself attempted to puncture the bladder above the pubis. Of those cases the commonest history was that the patient finding he did not pass water, generally took three or four glasses of gin or of whisky. Tapping the bladder was not so common as it used to be. In the Richmond Hospital for the past fifteen years there had been no necessity to tap the bladder.

Mr. W. WHEELER said he had tapped the bladder both above the pubis and through the rectum. The first case was that of a man from the north of Ireland, who, without injurious effect, had been tapped fourteen or fifteen times above the pubis with the aspirator before being admitted into Baggot Street Hospital. There was a traumatic stricture caused by a kick in the perineum. He got in a No. 1 catheter, and afterwards dilated him up to No. 8. It was Mr. Tufnell who passed the No. 8, and he, himself, having dilated the patient up to No. 6. The next case was sent to him from Parsons-town by Dr. Stoney, and was that of a man who had been tapped twenty-three times above the pubis. The man had lost one of his testicles as the result of a kick; and then the constricting and narrowing set in until he was not able to pass water except drop by drop, and, finally, he was not able to pass any until Dr. Stoney tapped him. Having tapped him above the pubis, he (Mr. Wheeler) drew off the water by means of the aspirator. Eventually he performed Cock's operation, and left him passing water through the perineum. He did not afterwards attempt to establish the continuity of the urethra. Dr. Quinlan's case of mixed stricture was interesting and instructive. There was both the organic and spasmodic stricture, the latter due to the patient's drinking, and over-distended bladder. The line Dr. Quinlan had adopted was the correct one. On the question of tapping, he (Mr. Wheeler) would prefer tapping above the pubis than through the rectum, to avoid the chance of the recto-vesicle fistula, while there was the certainty that the opening above the pubis would almost immediately close. In the many times he tapped a patient, he did not think he got exactly into the same opening, yet the patient was not in any way injured. There was no inflammatory action from the passing of the trocar. Sometimes a metallic instrument would pass in when a gum elastic would not, and he therefore desired to know if Dr. Quinlan had tried the former. It was a question where the patient was of advanced age, whether it would not be better to tunnel his prostate instead of tapping him. However, he believed Dr. Quinlan, having done everything that could be done as a *dernier ressort*, tapped the bladder, adopting the proper surgery.

Dr. W. FRASER never would forget the distress of a patient whose prostate he saw tunnelled, and his horror at witnessing his sufferings was such, that he hoped never to see another prostate tunnelled.

Dr. DOYLE mentioned that the late Mr. C. Fleming always impressed upon students to use the largest-sized instrument they had, and he spoke highly of the use of tobacco-stupes in cases of spasmodic stricture of the urethra. He had had several times treated such cases, and in one instance during the late frost, he passed in a large size conical-shaped French catheter with ease.

Mr. F. W. WARREN corroborated Dr. Doyle's statement, having seen in Steven's Hospital tobacco-stupes used with marvellous results.

The CHAIRMAN said in reference to the facility with which some people, as Mr. Ormsby observed, passed the catheter, he remembered many years ago a resident pupil passing the catheter when the patient was on his way into the operating theatre.

Dr. CRANNY mentioned a similar instance that occurred when he was resident pupil at Baggot Street Hospital. An old man came in with retention of urine. The surgeon in whose charge he was, failing to pass an instrument, left, giving him (Dr. Cranny) instruments for tapping, and a commission to try his hand. After some trouble he got in a No. 1 and a No. 2 catheter, and drew off eighty ounces of urine.

Dr. QUINLAN replied. While there was a good deal to be said on the comparative merits of tapping by the rectum, and tapping over the pubis, he agreed with Mr. Wheeler in preferring the supra-pubic operation, which was the favourite operation of his former instructor, the late Mr. Ed. Hutton. He

recollected well the dislike which the late Mr. Adams had to tapping the bladder. When resident pupil a bladder was tapped one night. Mr. Adams asked what light had been used? His reply was, "The large lamp with the reflector," which was got up for night operations. Dr. Adams rejoined, "Aye, there will be reflections thrown on that operation." The stricture was a mixed one. He did not use the tobacco-stape, in which he had great belief in cases of pure spasmodic stricture. He tried a metallic instrument, a No. 8 catheter, which he carefully warmed and oiled to give as little irritation as possible; but it would have been as easy to get in the lamp. Sometimes there was a great deal of chance in passing the catheter. When assistant-surgeon at St. Vincent's Hospital all were at work with a case of Dr. O'Ferrell's, but did not succeed. At last the consulting surgeon, Sir Philip Crampton came in smiling, gay and *débonnaire* as usual, with a flower in his button-hole and said "Just let me try." He put a No. 8 catheter, and in it went. Dr. Cranny's case was interesting in that the quantity of urine in the bladder was greater than he had ever heard of before. He rather agreed with Dr. Fraser about tunnelling the prostate, only that, in these times, surgeons had the enormous advantage of morphia hypodermically, and could do a great many things of a painful character, which might not otherwise be prudent.

Mr. TUFNELL, hon. sec. on behalf of Mr. Allen Edmond Douglas, read a paper on

SCALP WOUND FOLLOWED BY ESCAPE OF BRAIN SUBSTANCE AND ARACHNOID FLUID,

which will be found on page 266.

Recounting the recovery of a child from an incised wound on the forehead, with escape of medullary substance and arachnoid fluid. He related instances bearing out Mr. Douglas's statement. When a student in St. George's Hospital, London, a case occurred in which a boy, who was walking behind one of Cubitt's large dray horses, struck the animal over the quarter with a stick, and the horse kicked, and struck the boy with the cock of the shoe through the root of the nose, and penetrating the pia mater and the brain. He scraped away the brain with a dessert-spoon, and the boy did not suffer. Next was a case under the care of Dr. T. Geoghegan. When the soldiers practised ball-firing at Sandymount Strand, boys got money for the lead bullets. One boy was struck with a bullet which passed from side to side, right through both hemispheres of the brain. The brain was scraped away, and yet the boy recovered. Again, a man was blasting in a quarry, and on examining the fuse, the charge went off, projecting the bar through the frontal bone of his skull, and yet he recovered. In another case, a man was breaking into a house, when the servant with a pitchfork smashed his skull in, opening the frontal bone, and lacerating the dura mater and pia mater, and yet no bad results followed. The fact was that the anterior portion of the brain seemed capable of withstanding any amount of injury, and the mental faculties were uninterrupted, and recovery took place. But *per contra*, where the individual was hit posterior to the ear, the ball passed through the central portion of the brain, and life went out with the ball.

Dr. W. FRASER mentioned an interesting case of a boy who suffered an injury of the brain in Dublin many years ago. He was vexing a man who threw at him an Italian quilling-iron, which got loose from its sheath, rotated in the air, and struck him on the side of the head. Portion of the brain came away. The boy was treated at Jervis Street Hospital by Dr. Adams. Stupor and heaviness supervened, from which, however, he recovered, but he ceased to grow on the opposite side of the body. He was easily put into a rage.

The CHAIRMAN stated that, on the occasion of the burning of the Theatre Royal, Dublin, a shaft of bricks fell on a plumber and stove in a large portion of the frontal bone, scarcely less than the top of an ink bottle. He had but little symptoms of trouble. The bone was removed. For some time he was at home until he went on a spree, and he eventually died of abscess on the brain. In Mercer's Hospital they had had several cases of fracture of the skull in young persons without evacuation of brain matter.

Dr. DOYLE said it would be worth while watching in the case of the child treated by Mr. Douglas, whether the organ of speech would become affected.

Mr. W. WHEELER referred to a remarkable case exhibited at

the meeting of the British Medical Association in Cork by a doctor from Kerry, in which a woman who, having fallen into the fire, had burnt the frontal, the parietal, the temporal, and the occipital bones, leaving the dura mater exposed, and yet she had all her faculties correct. He remembered a case under Dr. Geoghegan, in which a boy, *æ.* between 15 and 16, got fracture of his skull, the bone was removed, and the brain protruded. Dr. Geoghegan, with a curved scissors, cut off portion of the right hemisphere of the brain, and yet the boy made an excellent recovery. On four or five occasions Dr. Geoghegan snipped off portions of brain with the scissors. In children he had frequently seen cases of head injury recover, but not so in adults, where there had been much of the brain injured. If the faculty of speech was presided over in the third left frontal convolution, as had been stated, the boy, whose right side had been affected, would not have any loss of speech. Dr. Fraser's case of the boy not being developed on the left side, was extraordinary.

Dr. DOYLE said the injury seemed to be more on the left side of the forehead than the right.

Mr. STORRY presumed that the child not having yet learned to speak, the right side would take on the function of the left, so that there would not be the same difficulty as in the case of a grown-up person, who would be accustomed to use the left convolution. The cases cited were of interest on the question of the perfectness of the human race; for it appeared they had got a great deal more brains than they used or wanted; that in fact they had got waste brains, like the waste lands of Ireland. However, with the increased means of education, and better development, they should reclaim the waste brain.

Dr. HENRY KENNEDY agreed with Mr. Wheeler that age had a great deal to say in recovery from head injuries. Who, that was in the habit of visiting the Rotundo Hospital, could have missed opportunities of seeing the extraordinary way the head was pressed and shaped in parturition, and yet the child was not a bit the worse? Though the deformity had been exceedingly great, especially where instruments were used, the child was brought alive into the world. He had seen instances of severe wounds where children had fallen down stairs, and also in the case of persons advanced in life, and not one of them died, though they lay for days unconscious. The only explanation he could give was that those were cases of pure concussion. One case occurred at Dalkey. There was a frightful wound, not in front, but at the side of the head, and the child, after lying for days in a state of stupor perfectly recovered. As regarded the loss of brain, and the continuance of the vital functions, such as Mr. Tufnell's cases, would bear it, it seemed strange and hard to account for; and his own explanation was that only one side as a general rule was injured. A part of the brain was lost just as one eye might be, but it did not follow that all vision went away too. The brain he took to be a double organ, and the loss even of a large portion of one side was not necessarily attended by loss of intellect. Shakespeare wrote that when the brain was out the man would die; but Mr. Tufnell's cases went to show that such a cause did not injure some people in the slightest degree.

Dr. QUINLAN stated that ten years ago there was in Vincent's Hospital a United States soldier who, in one of the great battles, had been struck by a shell, which carried away portion of the top of the skull, about as large as a half-crown, corresponding to the posterior fontanelle of a child. The poor man came to be treated for epileptic fits. He had the idea that at the time he was struck by the shell, a fragment of the bone pointed downwards; and he was told that a piece of the bone would have to be lifted. At the time of the injury he did not lose consciousness, though a considerable quantity of brain matter was got out. As in Mr. Tufnell's cases, the man appeared, so far as the loss of brain was concerned, to take no notice. The soldier came to have an operation performed. Before being done they treated him with bromide of potassium, which checked the fits. For several months all his mental and physical functions were perfectly performed, and there was not a single thing wrong with him except the epileptic fits, which the ordinary treatment with bromide of potassium completely removed.

CANOE OF THE TONGUE.

The CHAIRMAN suggested a discussion on operative surgery connected with the tongue by means of the new instruments. When he, himself, began his career, the usual mode was to operate with a ligature. After that came the *écraseur*. Now

they had the use of the scissors rapidly cutting from side to side, and proving a successful and satisfactory mode, avoiding foreign bodies in the mouth, and contusion of parts. Then cautery, with the galvanic wire, and more recently with the thermo-cautery scissors. He had seen the *écraseur* but not the scissors used. Of late years continental surgeons had advocated operating in cases of cancer of the tongue, not only where the glands under the chin were diseased, but where the disease extended, so as to necessitate the removal of the larynx, and portion of the pharynx with it. Those who had taken trouble to follow cases of malignant diseases of the tongue in workhouses and incurable hospitals that had not been operated on, would agree with him that even a few months' respite under such circumstances, were a great boon indeed. He was also disposed to think that were they bolder in their operations for malignant diseases, though they might have increased mortality supervening on the operation itself, they would have a larger space of life and freedom from suffering. He was aware that his opinion was heretical, but he had long arrived at it after careful observation.

Dr. QUINLAN believed the first scissors came to St. Vincent's Hospital, to be used in a case under the charge of the late Dr. O'Leary, and it acted in a satisfactory way, cutting almost as easily as a knife, and without hæmorrhage. When he began to practise the ligature was universally employed; then the *écraseur* was employed. The scissors cut the part by burning, but without producing the extensive burning that might be expected. Since the case to which he referred, they had not had one suitable for the operation.

Dr. HENRY KENNEDY said a number of cases appeared on record where it was impossible to tell whether they were malignant or not. Hemlock he could not speak for in reference to the tongue, but he could speak for it in reference to ulcers of the breast and of the uterus. Not that he had been able to cure a single case with it; but it was exceedingly useful in improving the general state of the patient, and it was far superior to the medicine lately come into vogue, and now on its trial in England, namely, Chian turpentine, as a general rule that medicine had not been successful. As to hemlock, there was ample evidence to show its power over malignant ulcers, and in circumstances of doubt he would not hesitate to have recourse to it at once, giving it in large doses. From his own experience he was in favour of the preparation known as *succus conium*; but the best was the extract of the same in large doses, not less than ten grains, the active principle being so volatile, while the Pharmacopœia prescribed from two to six grains.

The CHAIRMAN said the late Mr. Harvey used Chian in connection with chloride of zinc.

Mr. WHEELER did not think Chian would be of the slightest benefit; but as regards the doses he should not have the slightest hesitation in drinking half-an ounce of *succus conium* himself. As to the propriety of operating on the tongue, all were pretty much agreed that, if able to get behind the disease, and the floor of the mouth was not engaged, they should operate. Whether or not the cancer would return, they could not say. In an aggravated case, it was nearly four years since he operated, and there had been no return since. The entire tongue was removed. Hæmorrhage, and other untoward symptoms, followed the operation. If the patient felt pain in his larynx, emollients should be used. In a case in which he removed a large portion of tongue, it was with considerable exertion and promptitude the patient was saved from the results of extended inflammation. On nearly all occasions he had used the thermo-cautery, not the scissors, but the knife. The scissors he had in his last operation used for the first time, and thought it had a great advantage. It would be desirable to have a stronger bellows than the hand-bellows, in order to make a longer cut. Since the operation the man's temperature was not higher than 99, his pulse being at the highest 82, and he had no pain to make one uneasy.

Dr. CORLEY thought that Dr. Henry Kennedy's teaching, from which he so seldom felt inclined to differ, might, on this occasion if followed, lead to disastrous consequences. He admitted that Chian never cured a case. The only chance of success in any operation was to operate as early as possible, and, therefore, anything that would delay an operation, must be looked upon as a serious obstacle to the progress of surgery, and the safety of the patient.

Mr. L. ORMSBY concurred with Mr. Corley that the earlier the operation was performed the better, not only to cure the patient, but to relieve the patient's mind in the case of a disease that sooner or later must have a fatal termination. He

was one of those who believed that cancer was a blood disease, and the earlier the operation was performed, the longer would the cancer delay in returning again. He also concurred with Dr. Corley that cancer could not be cured by any medicine, and that the only proper and rational treatment was by operation. Curing cancer by hemlock or Chian turpentine was out of the question.

The CHAIRMAN did not mean to convey that cancer was not curable in its earlier stages. Epitheliomatous cancers were, he believed, easily curable. A small percentage of cancer lips and cancer penis had been successful.

Mr. WHEELER—Do you make any difference between scirrhus and epithelioma as to return?

CHAIRMAN—My observation was more particularly as regards epithelioma, as to which my statistics would be more favourable; but I have seen cases of scirrhus breasts in which for twelve years there has been no return.

The Society then adjourned.

Arsenic	...	...	0.38
Boracic acid, trace			
Chloride of sodium	...	...	21.14
Silica	...	...	2.00
Organic matter, trace			

Total ... .. 356.22

*Skeleton analysis of half-a-pint, or 10 fluid ounces:—*

Total Solids.	Antacids.	Salines.	Purgatives.
22 grs.	19 grs.	1 gr.	1½ grs.

This water and the next (Hôpital) are supposed to be the most ferruginous of the Vichy springs. It is also one of the springs which is supposed to give off sulphuretted hydrogen. There was no evidence of the presence of sulphides in the bottle examined; and we must, therefore, presume that those salts have all become oxidised. As regards the iron, the small fluctuations in the relative amounts of iron present are probably due to the different temperatures at which the waters rise. Many of the

springs, like Grande Grille, are said to be surrounded by an ochreous deposit.

Another of the best known Vichy waters is—

*Hôpital.*

It contains—

Bicarbonate of sodium	...	...	314 26
Bicarbonate of potassium	...	...	27 14
Carbonate of magnesium	...	...	12 32
Carbonate of strontium	...	...	0 26
Carbonate of calcium	...	...	36 00
Ferrous carbonate	...	...	0 23
Manganese, trace			
Sulphate of sodium	...	...	18 32
Phosphate of sodium	...	...	3 00
Arsenic	...	...	0 07
Boracic acid, trace			
Chloride of sodium	...	...	32 32
Silica	...	...	3 08
Organic matter, trace			
Carbonic acid gas, free, not determined			
Total			447 00

*Skeleton analysis of half-a-pint, or 10 fluid ounces:—*

Total Solids.	Antacids.	Salines.	Purgatives
28½ grs.	25 grs.	2 grs.	1 gr.

*Parc.*

This is another well-known Vichy water, frequently imported in the bottled form.

It contains—

Bicarbonate of sodium	...	...	298 00
Bicarbonate of potassium	...	...	18 34
Carbonate of magnesium	...	...	13 00
Carbonate of strontium	...	...	0 41
Carbonate of calcium	...	...	38 23
Ferrous oxide	...	...	0 24
Manganese, trace			
Sulphate of sodium	...	...	20 16
Phosphate of sodium	...	...	9 30
Arsenic	...	...	0 08
Boracic acid, trace			
Chloride of sodium	...	...	28 57
Silica	...	...	2 8
Organic matter, trace			
Carbonic acid, free, not determined			
Total solids...			429 13

*Skeleton analysis of half-a-pint, or 10 fluid ounces:—*

Solids.	Antacids.	Salines.	Purgatives.
26½ grs.	23 grs.	1½ grs.	1½ grs.

This analysis must conclude our notice of the Vichy waters. The others imported are Chomel and Célestins; but it will be perceived that all these waters, although complicated in character, bear a great resemblance to each other. The complexity of character probably has given rise to their celebrity. At any rate, this is a good example of how difficult it would be to imitate such springs artificially. Presuming it were possible to imitate them, how very improbable that in commerce such a formula would be adhered to, as would give an analysis resembling the original springs.

“SALUS POPULI SUPREMA LEX.

WEDNESDAY, MARCH 30, 1881.

THE CENSUS.

BEFORE the next number of the *Medical Press and Circular* is in the hands of its readers the population of this country will have been registered for the ninth time in the present century. The information yielded in the returns that will be made will be important and significant in the highest degree, and the scientific advantages which might be obtained in profusion from a full and proper employment of the powers conferred by the Census Act, will in a certain small degree accrue from the approaching enumeration. In the schedules distributed to each house there occur such questions as might be reasonably put to ascertain the outline facts concerning the inmates of the abode. But with them it would be by no means a difficult matter to include also other inquiries bearing on sanitary and hygienic conditions, the replies to which could not fail to afford a body of highly useful information to the practical reformer in sanitary questions. A number of the more illiterate classes would naturally return improper or deficient answers on everything that was not a direct and personal query, and it might very well be inconvenient and even impossible for the enumerators to correct the errors committed in every case. Notwithstanding, however, a little reflection must convince that the taking of the census affords an opportunity for gathering information about the people who constitute the nation such as can be afforded by no other means whatever. Some time, perhaps, we may see the realization of this belief, and the census availed of to obtain something beyond the mere mechanical data that are now yielded by it.

Judging by experience in former years we are led to anticipate that the population will be found to have increased by some two millions and a-half or so, since the last census, in 1871. It will be no more than we have reason to expect if the increase is found to bear a smaller proportion to the total numbers than has been the case on former occasions. In the last decade attention has been more generally and more carefully devoted to sanitary surroundings, a greater impetus has been given to the improvement of the public health, than has occurred in any similar period within the century. That, under ordinary circumstances, the births will exceed the deaths, may be taken for granted; new lives will come into existence with far more frequency than old ones die out, so long as no means are generally resorted to for putting a check on the growth of the excess. That a time will come when the number of inhabitants, even in England, will be greater than the country's resources are competent to maintain, is likely enough, especially since the future seems destined to witness an increase of efficiency in those benevolent but unscientific precautions that are taken to preserve the indigent from destruction. If the preservative measures in use to provide those who will not help themselves with the means of living continue, and are yet further increased in extent, as many weak, but good-hearted persons are always striving to secure, then it must necessarily occur that each period of reckoning will detect a growth in the numbers of the unproductive classes. The economist regards this with feelings of uneasiness that have no place in the philanthropist's bosom. The former knows that the prosperity of a country is not indicated solely by the number of its inhabitants, if they are mainly of the class from which no return is to be expected; if, that is, they are *consumers* only, then the number of them is an indication of weakness, and far from being advantageous, if the malproportion long continue, it will entail absolute ruin. In India, for instance, we have just now an example. The native population do not, in any sense, add to the riches of the country; each year sees new misery added to that already existing, and in the preventative measures that have done so much for the people of India of late years, we cannot help but remark a direct interference with the course of those natural laws on the action of which the maintenance of a due proportion of inhabitants depended. A gentleman, for years residing as an official in India, and a close observer of the conditions which obtain among the native population, declares emphatically that the tendency of the measures taken to preserve the people from the ravages of famine will be to create, at no very distant time, a state of things infinitely worse than any crises that have yet occurred. The recurring famines, he urges, must be regarded as a natural means of re-establishing a just balance between the producing and the consuming factors in the country; and in this light it must be contended that it is of the highest importance to recognise exactly what that proportion is for our own country. The census, as it is, does not do this; all it does is to afford a rude and clumsy means of guessing more or less certainly what the relation may be. The census, as it could be made, would afford every detail of information of this kind, and much more that, to the otiologist and the practical physician, would prove in-

initely serviceable as bases of investigation and work. Here, fortunately, there can be no question at present of any possible swamping of the producing by the consuming classes, and probably the progress made in every branch of art and industry will always more than outweigh the increasing disadvantages of an ever-growing dead weight of idle poor. But that this section will rapidly grow in the future unless more favour is shown to schemes for its diminution, is certain. Each improvement in hygienic conditions adds we know not how many to the number of those who but for it would die; and, from the nature of things, from the fact that the greatest improvements remain to be made among the habitations of the poorest persons, it must follow that it is the poor chiefly who are adding, and will add, to the numbers announced at each decennial reckoning. The aim of medicine is to banish sickness: *salus populi suprema lex*. The physician and the hygienist work to the end that the relative number of the sick and the dead shall sink lower and lower with each year; into his calculations no question of the supporting capacity of the State enters; he is concerned only to improve the health of the aggregate nation. The census returns have for him a peculiar truth; they tell with unerring truth whether or not his endeavours are being crowned with success; and, together with the periodical local returns of health officers, they enable him to determine with precision in what direction his efforts are more especially required, in what respect they have failed to have effect.

In a purely professional sense the interest of the census returns centres in the information afforded in them of the progress made in the struggle with disease. As we have ventured to affirm, much more valuable knowledge of the national constitution might be gleaned if the opportunity were rightly used; as it is, inference, and not direct reading of facts, assists in the deduction of those truths the census is calculated to reveal. As a necessary engine for conducting the affairs of a country its importance is inestimable; as the usefulness of it in other relations becomes more apparent it will doubtless be modified to secure through it the utmost available good.

#### MEDICAL OFFICERS IN THE ARMY.

ON 21st of March Mr. Findlater asked the Secretary for War whether, having regard to the cases of wounds and sickness which have occurred amongst medical officers during recent campaigns, he will take into consideration the justice of extending to the Army Medical Department the privilege of counting as full-pay service towards retirement any time on half-pay, not exceeding one year, when such half-pay has been necessitated by sickness incurred in and by the service; also of such half-pay as results from reduction of the department, not exceeding two years, as laid down in Army Circulars, March 1st, 1880.

To this Mr. Childers replied that he could not undertake to lay down the broad proposition that non-combatant officers are to have all the advantages of combatant officers, unless the converse be also accepted—that is to say, that they are to have all the disadvantages. Regulations as to the retirement of medical officers have been so recently settled that he could not undertake to open

the question; but when he had more leisure he would look into it.

In his reply, as given above, the Secretary of State for War was careful to avoid the precise question submitted, and equally careful to enter upon points having reference to members of the Army Medical Service, which can to them have no other meaning than that they manifest, on his part, an adverse feeling towards them and their just claims.

As embodied in the question addressed to the Secretary of State, it is a mere matter of right and justice that medical officers disabled by wounds received while in the performance of their special duties on the field of battle, or by sickness contracted on service, should obtain exactly the same degree of consideration, neither more nor less, accorded to other classes of officers under similar circumstances. This claim is more particularly reasonable at the present time, when there are an unusually large number of medical officers interested in the decision given regarding it. Moreover, those now in England suffering from the effects of wounds and sickness, contracted with the troops in Afghanistan and Southern Africa, feel deeply aggrieved and injured at an invidious distinction being drawn between them and the "executive" officers, whose toils and risks they shared quite in an even—and in some respects greater—degree. This feeling will be increased rather than diminished by the remarks of the Secretary of State regarding non-combatants, as if all other branches of the army with the exception of that whose duties consist of actually fighting were, from that very circumstance, of relatively inferior consequence in the general work of a campaign. Not only do a considerable proportion of medical officers perish by wounds in all campaigns, but, with very few exceptions, the general proportion of casualties among them from such causes, and by disease, is far greater than among the purely "combatant" classes. Hence it is that to draw such a distinction as is indicated in the answer by the Secretary of State for War, is calculated to rouse afresh much of that want of confidence in the *bona fides* of the higher authorities towards them, which they were fain to hope had been lulled, if not altogether allayed, by recent concessions made in the shape of pay and retiring allowances. They will naturally endeavour to find out what are the *advantages*, except the one of full pay enjoyed by medical equally with "combatant" officers. Nor will it be easy to discover in what they consist. The *disadvantages* however are manifest, and by no means few, including prospects of promotion, high official position, and its emoluments, leave of absence, honorary distinctions, and so on. So long as in these, and other respects, the different branches of the one great service, the army are dealt with by the War Office authorities on the system of "fish, flesh, and fowl," so long invidious comparisons and dissatisfaction must be liable from time to time to crop up among them.

The same glaring injustice was perpetrated in the recent distribution of honours to officers in connection with the war in Afghanistan. Among the recommendations submitted by Lord Cranbrook's Committee was that honours should be awarded to army medical officers according to the scale of "combatant," instead of "uncombatant"

branches of the service. Not only is this not done, but there appears to be a decided disinclination to grant honorary distinctions even according to the scale, meagre as it was, by which they were conferred, prior to the issue of the very latest warrant for the department. In thus acting, the authorities concerned should at the very earliest opportunity learn that they are simply storing up for themselves difficulties such as they have over and over again experienced in regard to the department towards which they so act. "Doctors," like other men, and especially those who share all the risks and hardships of active campaigns, look—and rightly look—for fair recognition, similar to that accorded to other officers of corresponding rank for similar risks and hardships undergone by them.

#### THE NOTIFICATION OF INFECTIOUS DISEASES.

MR. GRAY'S Bill for the extension of the notification system to Ireland, stands for a second reading on this day (Wednesday), and as it is second on the notice paper, it will probably be discussed. We understand that the Committee of Council of the Irish Medical Association have presented, through Dr. Lyons, M.P., a petition to the House of Commons against it. The ground taken by that petition we believe is that, however desirable it may be that all cases of infectious disease should become known to the sanitary authority, it is doubtful whether a stringent law might not in Dublin do more harm than good, by causing persons who are in dread of sanitary precautions to conceal the disease in order to avoid the publicity of disinfection and removal of sick to hospital; and, furthermore, that if it be desirable that some one be forced to notify, that some one should, certainly, not be the physician. Lastly, that, if the medical attendant were to be compelled to do this work, the fee proposed is altogether unacceptable, while the penalty imposed is equally objectionable. Mr. Gray's Bill stands for a second reading on March 30th, after which we hope we shall hear no more of it until it has been radically modified.

*Apropos* of this question, it is deserving of remark that there seems to be great doubt as to the truth of the statement frequently made in support of this Bill—that the duty of notification is discharged with great cordiality and enthusiasm by the medical practitioners of English towns in which the system is in operation, and that it may therefore be assumed that, when Dublin physicians come to be familiar with the working of the law they will be equally in love with their employment as sanitary detectives. In the *British Medical Journal* of last week—the representative organ of the notificationists—we find a statement that, at Jarrow, the system does not work without an occasional jar. A medical man was there prosecuted for omitting to notify, but was acquitted on the ground that he had given notice of the occurrence of a case of "infectious disease," and that at the time of notification he had no information to be more explicit. Suppose he had, as we suspect is often done to please the patient, certified the case as one of febrile herpes, how could he be punished if he pleaded error of judgment, and would not a *nidus* of infection, in such case, remain undetected

Again, if, as we are told, the duty of advertising the sanitary authority that our patients need to be disinfecting is so pleasing and remunerative, what is the meaning of the following paragraph cut from a pamphlet recently published by the Medical Officer of Health for Kensington, for the purpose of persuading his vestry to adopt the notification system :—

“This duty of direct notice by the medical practitioner, be it at once stated, is in disfavour with the profession generally, who, excepting in the case of Bolton, referred to above, have not been able to overcome their repugnance against an apparent breach of the confidence which should always subsist between patient and doctor; and any attempt to pass an Act for London, devolving such a duty on medical men would meet with strenuous and probably successful opposition.”

Considering that this statement comes from a zealous advocate of notification, it may be accepted as strong evidence that the medical men of Dublin are not alone in their hostility to the proposal to force upon them the function of infection detectors to the Corporation. To be candid, we are somewhat sceptical respecting the rose-tinted reports given of English and Scotch medical officers of health. They are sanitarians *et preterea nil*, and cannot be expected to acquiesce in the view that sanitary changes should diverge from their course in deference to the opinions and interests of medical men. Nor can it be expected that a certain class of English and Scotch general practitioners, who are accustomed to make their living by very small fees, and by any and every sort of medical work, will fully understand the objections felt by Irish physicians, who do not keep books or run bills, and who, as their usual fee is £1, do not covet the privilege of earning 1s. by a month's notification of an infected house.

## Notes on Current Topics.

### Artificially-Matured Cheese.

It is well known that the improvement effected in cheese by age is a gradual conversion of the albuminous constituents into more or less discoverable but veritable oil. The ingenious American, taking advantage of this fact, now prepares by artificial means a cheese possessing the oleaginous excellence of the well-matured article. This is effected by the addition of lard to milk, the manner and proportions being described in the *Scientific American*, of March 19th. To 100 pounds of milk a pound and a half of lard is added—the best quality only being used for this purpose, and it being previously specially deodorised by blowing hot steam through it. About ten pounds of cheese are produced in this way from each hundred pounds of milk; and it is described as being of good quality, and commanding a ready sale, which is helped rather than otherwise by the knowledge of its being *lard-cheese*. One manufacturer asserts that during 1880 he made 2,500 boxes, of 60 pounds each; and the call for the article shows no prospect of diminishing. Chicago, Boston, New York, and Baltimore are given as the names of the places to which the foods are consigned. It is not improbable, however, that no inconsiderable proportion finds its way to this country; and in that case we do not need to object seriously to the fraud practised where it is

purchased for veritable cheese. It is, of course, deficient in actual nitrogenous material, since this has not at any time been so largely part of the bulk as in ordinarily prepared cheese. There is no reason, however, why, from a dietetic point of view, lard-cheese should not compare favourably with its better-known similar.

### Infectious Epidemics.

THE question of the spread of infectious diseases, and the means of reducing the evils consequent on it, was discussed recently at a meeting held at the Kensington Town Hall, and attended by delegates from the various Metropolitan Vestries, and District Boards of Works. A resolution was carried unanimously, calling on the State to provide for the compulsory notification and isolation of cases as they occurred. A second resolution urged “that the admission into hospitals for the purpose of isolation of persons suffering from infectious diseases, and being without proper lodging or accommodation, is eminently desirable in the interests of the public, and should be encouraged; that payment for the assistance given in hospitals to such persons removed thereto for isolation by the Nuisance or Poor-law Authority should not be enforced; that the giving of such assistance should not entail on the recipients the loss of any social or political status; and that the cost of hospital treatment of such infective sick persons should be made a charge on the Metropolitan Common Poor Fund.”

This was also carried by the full consent of the meeting, and it is, perhaps, one of the most likely to result in good, submitted to it. Steps were also taken to bring the resolutions to the notice of the Government, and to show the strong feeling in the metropolis in favour of carrying out the suggestions they embody. That they will result in any satisfactory improvement may perhaps be too much to hope for, but as the constant dropping of the water wears the stone, so by perpetual insistence on the crying need there is for reform in the treatment of infectious diseases among the poor, attention may at length be forced to it.

### The Land League and the Hospitals.

THE following statement appears in the report of Sir Patrick Dun's Hospital :—“During the year 1879 the hospital suffered a deficiency of income from the non-payment of rent of Sir Patrick Dun's estate, amounting to nearly £400, and in the year 1880, the deficiency arising from the same cause amounted to more than £600.”

### Workmen's Contributions to Hospital Funds.

MR. F. W. LOWNDES, F.R.C.S., sends us an appeal made by the Council of the Fund to the proprietors of the leading commercial houses in Liverpool, relative to the forthcoming Hospital Saturday collection in that town on May 21. Liverpool with its population of half-a-million, has always been behind smaller towns in its hospital contributions, and the managers not unnaturally think that this is due, not so much to any objection on the part of the working classes to contribute, but to the lack of interest and judgment on the part of employers and foremen. Were these to offer suggestions and facilities to

the men to drop but a penny a week into a box for the purpose on pay-days, none would miss it, and at the end of a year it would form a handsome contribution to the Fund. Whereas now, men are simply asked to contribute on one day in the year, and the result is a very paltry total. This is exactly the argument we put forward in the early days of the metropolitan Hospital Saturday Fund, and where adopted, excellent results have followed.

### Signs of Death.

DR. VERGA AND BIFFI (*Nature*) have arrived at the following conclusions regarding the last manifestations of life in animals:—1. In the higher animals, when sensibility, circulation, and respiration have ceased, the life of histological elements of the nervous centres, especially of the ganglionic system, and the spinal cord, remain for a short time. 2. Contraction of the pupils, and of the spleen, are effects of this reduced latent life, and more remarkable effects, in guinea pigs, rabbits, and cats, are the constant and uniform movements of inward curvature, which have the significance of respiratory efforts, presented under like conditions by the dog and the ass. 3. These movements appear in the animals whether drowned in water, or hanged, or bled to death. 4. They indicate the point beyond which the organism loses the power of recovery.

### Transpiration of Plants.

PROFESSOR WEISS has communicated to the Vienna Academy the result of a number of experiments from which he concludes, says *Nature*, that transpiration is only prejudicial to the functions of plants, excepting the process of liquification of the *cell-walls*, which it favours; hence it is to be regarded as a necessary evil for plants. Professor Weiss also obtains striking evidence in favour of Weimer's theory of heliotropism; and he seeks to prove that through transpiration certain inorganic constituents of the ground are carried to the plant in excess, and are got rid of on the fall of the leaves in autumn, and consequently that transpiration is also the cause of the influence exercised by the nature of the ground on the quantitative composition of the ashes of plants. The view that the stronger growth of non-transpiring plants is due to mere expansion of cells without simultaneous overproduction of organic substances is controverted.

### The Indian Medical Service.

THE *Times of India*, in a late issue, intimated that under the recent Royal Warrant for the Indian Medical Service, the establishment for the Bombay Presidency would consist of eight brigade surgeons. The names of eight surgeons-major have been submitted for promotion to the rank of brigade surgeon; but this promotion is governed by selection and not by seniority. There is certain to be much discontent and irritation among the surgeons-major on the establishment when the names are published in the *Gazette*; and not, perhaps, altogether without cause. Out of the eight selected for the appointments, as many as six hold substantive civil appointments, and we believe the Commander-in-Chief has himself raised the question whether this increased military rank

was ever intended for men performing purely civil duties, and who are not likely to have even that slight connection to a military career implied by the possession of a uniform.

### The Thermo-Cautery in Hydatids of the Liver.

M. CHAUVEL described before the *Société de Chirurgie* lately a plan for opening the cysts of hydatids by means of the thermo-cautery (*La France Médicale*). He expressed himself in favour of this means of incision over the ordinary bistoury, for dividing even the soft parts necessary to pass through to reach the liver. The case quoted by M. Chauvel in illustration had been frequently relieved by means of capillary punctures; but at the time when the final operation was performed, two litres of pus came away, notwithstanding. The subsequent history was favourable, and such as to encourage M. Chauvel in advocating the adoption of the plan he had followed in many such cases.

### Chemists' Charges.

A FORCIBLE illustration has recently been given to the theory that the extortionate charges of chemists are a main cause of crowding the out-patient departments of free hospitals. A physician writes to *The Standard* that he prescribed gratuitously for a female patient an ointment consisting of hydrarg. ammon. gr. xx., in  $\zeta$ iss. of lard. For this the chemist to whom it was taken exacted *eighteen-pence*, and this, too, from an obviously poor woman. So long as this excessive overcharge is maintained, it is but natural that people unable to pay such exorbitant rates will resort to the institutions where they will be supplied without cost with the medicines their cases demand, even when to obtain them involves a loss of three or four hours. Chemists should be brought to recognise the serious injustice their tariff imposes on the poorer classes of society.

### Carmichael College (Dublin) Musical Society.

THE initiatory effort of this society was made on Thursday last, and resulted in an unequivocal success. The society is the first of its kind in Dublin, and, as its balance in hand (we suppose we must add—if any) is to be handed over to the Royal Medical Benevolent Fund of Ireland, it merits our good wishes if only for its charitable intentions. But an effort to induce medical students to devote their leisure to so harmless and so refining a pursuit as music, is eminently deserving of approval, and we trust that the new society may succeed because of its elevating influence upon those who belong to it, and because of the good example thus shown to others.

The performance of Thursday last was an excellent beginning, and the goodwill of the professors of the College was shown by the participation of two of them in the performance. The instrumental pieces were especially creditable, the singing of Miss Connell was cultured and careful—the performance of Hayden's humorous trio, "Maiden Fair," was admirably clever, and other contributions to the programme by members

of the society and lady executants were pleasing, and quite up to the usual standard of such performances.

If we may be excused a friendly criticism, for the benefit rather of the exuberant members of the audience than of the performers, we would suggest that if every piece in the programme is in future to be encored, a shorter list of music will be desirable. Invariable repetitions are liable to prove wearisome.

We don't know whether any one now survives who believes in the old theorem, that a young man is the worse student because he has a liking for music. If the Carmichael Society can catch a specimen of that genus and bring him or her *vi et armis* to its next concert, we have no doubt that a permanent cure of that hallucination will be effected.

#### A New Gustatory for Cod Liver Oil.

In the *American Journal of Pharmacy* Mr. Fairthorne suggests a new method of taking cod liver oil, which consists of adding ʒij. of tomato or walnut catsup to each ounce of the oil, the mixture being shaken before taken. He very pertinently remarks that taking an ordinary emulsion of cod liver oil is like eating codfish or lobster with a dressing of sugar and gum. He has found the mixture of catsup and cod liver oil to agree with many persons better than any other form in which cod liver oil had been taken, and this he attributes to the association of substances generally employed as additions to food bringing into operation those digestive faculties of the stomach which might otherwise remain dormant when such incongruous substances as sugar and one of the principal ingredients of fish are introduced together into the stomach.

#### The Future Probation of Naval Medical Cadets.

A MEDICAL contemporary hears that the candidates for commissions in the Medical Department of the Royal Navy, who succeed in passing the competitive examination in London, will subsequently go through a course of instruction in naval hygiene and other special subjects at Haslar, where a Naval Medical School will be established on the same principles as the Army Medical School at Netley, which the successful candidates have hitherto attended. Inspector-General Dr. Macdonald, R.N., who has been the Professor of Naval Hygiene, and who has ably taught the subject for some years past at Netley, is *not* to be one of the teachers at the new school at Haslar.

#### Poisoning by Arsenic.

A SHOCKING case of wholesale poisoning has just occurred at Binbrook, a village on the Lincolnshire Wolds. Mrs. Gibson, the wife of a shepherd, made a number of cheesecakes. After eating one of them she suddenly became unwell, and the neighbours who visited her, and who had eaten some of the cakes, were also taken ill. Upon testing some of the cakes it was discovered that the woman had mistaken a tin of arsenic for ground rice, and had mixed the poison in her pastry. The arsenic, which was used by her husband in dressing the sheep, was kept in a cupboard in a tin precisely similar to that which

contained the ground rice. The woman died a few hours after she had eaten the cake, before medical aid could be obtained, and eight or nine of the neighbours remain seriously ill from the effects of the poison.

#### Drug Adulteration.

THE *Pharmaceutical Journal* says that the adulteration and admixture of crude drugs, especially among those imported from Germany, seems as frequent as ever. During the present month *Helleborus niger*, consisting principally of the root of *Actæa spicata*, has been noticed, and copalchi bark had been picked out of cusparia, while dried dulcamara has been offered in bundles under the name of chirata.

#### Kinkead v. Browne.

WE are gratified to hear that this action for defamation of professional character, which was to have come up for trial at the Galway Assizes, and the particulars of which were recently given in these columns, has been settled by the withdrawal of all imputation upon Dr. Kinkead, who has, thereupon, withdrawn the record.

THE black plague has broken out in and around Bagdad, the inhabitants of which have been subjected to a disinfecting process and left the place, the houses of which are also being disinfected. The mortality is very great, and the authorities have taken further sanitary precautions against the spread of the disease.

THE rates of mortality last week in the principal large towns of the United Kingdom per 1,000 of the population were—Bradford 15, Hull 16, Plymouth 16, Birmingham 17, Leicester 17, Sunderland 18, Leeds 18, Brighton 18, Salford 19, Edinburgh 19, Sheffield 20, London 20, Norwich 20, Bristol 21, Nottingham 21, Newcastle-upon-Tyne 21, Portsmouth 22, Oldham 22, Manchester 23, Liverpool 25, Glasgow 25, Wolverhampton 26, and Dublin 30.

IN the principal foreign cities, the rates of mortality, according to the latest weekly official return, were:—Calcutta 33, Bombay 34, Madras 46; Paris 30; Geneva 19; Brussels 24; Copenhagen 22; Stockholm 32, Christiania 19; St. Petersburg 52; Berlin 23, Hamburg 24, Dresden 26, Breslau 35, Munich 29; Vienna 32; Budapesth 37; Rome 33; Naples 36, Turin 33, Venice 25; New York 32, Brooklyn 24, Philadelphia 21, Baltimore 17 per 1,000 of the various populations.

OF diseases of the zymotic class last week in the large towns, scarlet fever showed the largest proportional fatality in Leicester, Portsmouth, Edinburgh, and Newcastle-upon-Tyne; and whooping-cough in Glasgow, Bradford, and Liverpool. Of the 10 deaths referred to diphtheria, 9 occurred in London, 5 in Glasgow, 5 in Edinburgh, and only two in the other towns. The death rate from fever was highest in Leicester, Newcastle-upon-Tyne, and Manchester. Small-pox caused 46 more deaths in London and its suburban districts, 2 in Dublin, one in Liverpool (of a coloured seaman recently landed from New York), but none in any of the other towns.

## Scotland.

(FROM OUR NORTHERN CORRESPONDENT.)

**THE MORTALITY IN GLASGOW.**—The deaths in Glasgow for the week ending with Saturday, the 19th inst., were at the rate of 25 per 1,000 per annum, as against 25 in the preceding week, and 24, 25, and 29 in the corresponding periods of 1880, 1879, and 1878.

**HEALTH OF EDINBURGH.**—For the week ending with Saturday, the 19th inst., there were 81 deaths in Edinburgh, and the death-rate was 19 per 1,000. Only one fatal case of fever was reported in the Old Town. The southern suburbs were entirely free from zymotic diseases.

**LECTURESHIP ON ANATOMY AT SURGEON'S HALL.**—At a meeting of the Lecturers of the School, held on the 21st inst., Dr. Cathcart, one of the Demonstrators of Anatomy in the University, was unanimously elected to the Lectureship on Anatomy vacant by the death of Dr. Handyside. Dr. Cathcart is a gentleman of high professional attainments. He is a graduate in Arts and Medicine of the University of Edinburgh, a Fellow of the Royal College of Surgeons of England (by examination), and a Fellow of the Royal College of Surgeons of Edinburgh.

**VITAL STATISTICS OF LARGE SCOTCH TOWNS.**—From the Registrar-General's weekly returns we learn that the death-rate in the eight principal towns during the week ending with Saturday, the 19th March, was 23.1 per 1,000 of estimated population. This rate is 0.6 below that for the corresponding week of last year, and 0.3 below that for the previous week of the present year. The lowest mortality was recorded in Leith, viz., 14.7 per 1,000, and the highest in Paisley, viz., 33.9 per 1,000. The mortality from the seven most familiar zymotic diseases was at the rate of 3.8 per 1,000, being an increase of 0.6 on the number for last week. Acute diseases of the chest caused 164 deaths, or 4 less than the number for the preceding week.

**THE RUSTICATION OF STUDENTS OF ST. ANDREWS.**—In our last we referred to the ill-judged action of the authorities in this matter. A crowded meeting, in the Town Hall, has since been called, with a view of eliciting public opinion on the subject, Provost Milton presiding. Several resolutions were passed to the effect that the public do not disapprove of the ancient custom of the students celebrating Kate Kennedy; that the conduct of the processionists was not such as to give offence to the public; and that the meeting authorise the Provost to sign a petition to the Senatus to that effect, and respectfully ask them to consider the rustication decision. Sir James Ramsay took exception to the second resolution, and moved an amendment that "the conduct of the students did cause annoyance to a section of the public." He produced two letters in support of this motion, one of them being from Bishop Wordsworth, whose house the masqueraders had invaded against his will. Sir James reviewed the demonstration from several points of view—the general public, professors, students, and parents. He was subjected to much interruption, and, on the amendment being put only two hands were held up. Other resolutions were carried unanimously. All the speakers abstained from saying anything likely to place the public and the college authorities in antagonism.

**H.R.H. THE PRINCE OF WALES** has consented to preside at the Festival Dinner at the Royal Hospital for Children and Women on May 9th.

## Literature.

THE YEAR-BOOK OF PHARMACY FOR 1880.

THIS now well-known annual publication brings the abstract of work done in pharmacy and the allied sciences to the 30th June, 1880, and includes the Transactions of the British Pharmaceutical Conference at Swansea. It contains an abstract of all papers in pharmacy, materia medica, and chemistry, or professes to do so. We think we may congratulate the editor or editors in having succeeded much better than usual in this respect. Instead of being a simple *resumé* of the *Pharmaceutical Journal*, as some of the previous volumes were, the present editor has evidently extended the sphere of his reading.

The Year-Book of Pharmacy was always an interesting and useful book. We think the one for 1880 has certainly improved upon its brethren. The researches upon the alkaloids, atropia, and hyoscyamine, by Ladenburg, will be read with particular interest. In these researches, the actual identity of their derivations, if not actually proven, is rendered almost certain, at least their intimate relationship is self evident on reading Prof. Ladenburg's experiments. We may also mention as worthy of especial interest, Mr. Dott's researches on hydrochlorate of berberine, by which the formula for that alkaloid is now established. Prof. Selini reports the existence from a putrid corpse of a poisonous alkaloid differing in its reactions from any known base.

## Literary Notes and Gossip.

THE month of March has been exceptionally sterile in the production of new works or new editions; in fact, with the exception of "The Collected Works of Dr. Sibson," no book of any importance in medicine or its contemporary sciences has been issued in this country. Nor do we hear of much literary activity in progress; a few students' works are in preparation, but there is a marked lull in the production of "the minds of great men."

THE absence of an International Copyright Act is beginning to be felt in America, a circumstance not to be regretted, as hitherto the advantage has been all on one side; a few piracies in this country will do more to pave the way for the establishment of a law which shall protect equally the rights of authors in both countries than the deliberations of any number of Royal Commissions.

THE alleged complaint of piracy by an English author of an American book is now before us in the shape of a letter from the aggrieved party, having reference to a recently published "German-English Dictionary of Medical and Scientific Terms" in this country, which the American author avers is an almost verbatim copy of his work throughout. Not having the two books for comparison, we are unwilling to believe that this is so; dictionaries like directories must necessarily bear a family likeness, although their compilers may not have previously seen each others' work.

CATALOGUES are an admitted necessity to readers and authors alike; each firm has its own ideas as to style and arrangement, and it is interesting when wading through these productions for the title or authorship of some required book, to notice the care in classification and alphabetical arrangement bestowed by one firm as compared with another. Mr. Lewis has now sought to remove the inconvenience of a multiplicity of catalogues, by embracing in one, the principal works of all the medical publishing houses. Of course, this is by no means perfect, as we have tested it for several works, and find it wanting; but as a first attempt it is commendable, and will be found decidedly useful to authors and others.

IT is with extreme regret we hear of the death of Surgeon George A. Otis, well known in this country in connection with his labours as chronicler of the surgical and medical history of the American War. Surgeon Otis was some time editor of the *Richmond Medical Journal*, and was at the time of his death in active work at the Surgeon-General's office, War Department, Washington. The last efforts of this distinguished surgeon were devoted to completing the third and

last volume of the memorable "Medical and Surgical History of the War," a work with which he will ever be honourably associated by name.

AMONG the "Curiosities of Literature" may be ranked the fast growing demand made for *editions de luxe* of standard authors in this country. It would appear that the desire to possess the works of great thinkers in a choice and valuable form, is about to be a feature of the future, and that it will not be the lighter literature alone to which the honour of costly production will be accorded. Messrs. Macmillan have just issued a beautifully mounted edition, in four volumes, of Dr. Sibson's works, and we are informed that the example thus set may soon be followed by another well-known firm with respect to a little known, but widely appreciated physician of the past.

WE have received an advance copy of the *Leisure Hour* for April, which is quite up to its customary standard of excellence. The serials in this periodical are entertaining, of a high moral tone, and its "varieties" column very instructive reading. We cannot imagine any periodical more suited for the waiting-room table of consultants than the *Leisure Hour*, any number can be taken up with profit; as a family periodical it has no equal, and its cost—sixpence, monthly—is an additional recommendation.

WE are pleased to hear that at a meeting of about two hundred students and members of the Council of Edinburgh University, held on Friday last, a committee was appointed to take steps for raising a memorial to the late Thomas Carlyle, who was for some time Rector of the University. It was agreed that the memorial should take the form of a lectureship, the subject to be afterwards considered. Carlyle was undoubtedly one of the most profound and philosophical of thinkers the present century has produced. His style was trenchant, at times even discourteous, but it was always honest, and his works will be handed down side by side with Thackeray, and other great writers, as imperishable monuments of genius.

"A MANUAL of what every Mother should Know," by Edward Ellis, M.D. is the title of a little book just to hand, and the kindest thing we can say of it is, that it contains "what every mother should not know." It is bad enough to have prescribing chemists, worse that we should try to make every woman her own doctor. True, the author instructs mothers in pages here and there to send for a medical man, but why fill the book with prescriptions if the doctor is to be fetched. Clearly many who are tempted to buy the book from its title, would be equally anxious to try a little amateur doctoring, with what sad results cases are probably within the experience of most of our readers.

AFTER all, the American medical journals are, some of them, excessively amusing productions. The *Cincinnati Lancet and Clinic*, for instance, in a recent issue, gravely informed its readers that a newly-fledged "Dr." of the class of 1881, is about to start "for several years of study in Europe." It is probable that some undercurrent of fun is connected with this announcement that a student is struck with the aim of perfecting his education, and that there is a reason, not apparent in the *Lancet's* statement, to account for the curious prominence given to the promise of presenting its readers with "some items of medical news, which he will send us from London, where he will spend the summer." We trust this glorified youth will favour us with an early visit.

VETERINARY medicine and surgery has only, within the last seven years, found a home in America; the College and Hospital devoted to this specialty in New York being little over six years old. From *Harper's Weekly*, an admirably got up, and well-stored illustrated paper, we learn that the institution is both successful as a hospital, and appreciated as a school, numbers of graduates proceeding from it to fulfil the functions of veterinarians in different states of the union. It is hardly possible that a single college can supply America with skilled practitioners of veterinary medicine; probably the success attained by the first institution of the kind will encourage the creation of other similar centres of education. The more need of this since the only veterinarian specialist in Louisville, according to the *Medical News* of that place, has been removed from the post of superintendent of the stables

of the "fire department," in favour of an old-fashioned "hoss-doctor."

THE *Athenaeum* notes the decease of Mr. F. A. Robert, whose productions at least are familiar to every working microscopist. Mr. Robert was the manufacturer of test-plates and the more delicate micrometers, in ruling which no one could vie with him. He considered, at one time, that his nineteenth band, which was the 1-10,000th of a Paris line—equal to about 112-000 lines to the English inch—could never be seen resolved in the microscope. Dr. Woodward, however, succeeded, after infinite trouble, in photographing even the finest of these lines, and this led Mr. Robert to make fresh exertions, and the result was that he produced a new plate divided into twenty bands, the first ruled at the rate of 1,000 to the Paris line, and the last at the rate of 20,000, or about 224,000 to the inch. Even these, almost inconceivably minute markings, however, we shall probably ere long be enabled to see with comparative ease when the new American high-power comes into general use.

THE late A. H. Garrod, Professor of Zoology at King's College, left a considerable number of scientific papers, some of which were not without interest to the comparative anatomist. These are about to be collected in a single volume, and it is announced that early application is necessary by anyone who wishes to possess the work, since the number to be printed is strictly limited. This is a somewhat strange announcement, for if the volume have any value at all it must be in a scientific sense, in which case it cannot become too widely circulated. If, on the other hand, it is intended to be only a *souvenir* of a friend, then the act of subscription is scarcely a proper one. Prof. Garrod's contributions to myology were, several of them, such as might be useful to the student of classification; and in addition, he published a few other papers that are not without a permanent importance. Mr. H. Herkomer is to execute an etching of Mr. Garrod as a frontispiece to the book.

AMERICAN philanthropists, when they do venture on provoking the gratuity of posterity, do it in a way to ensure success wherever this is at all attainable. Whether it be a munificent donation for a special occasion of relief, or a bequest to make permanent provision for future multitudes, it bears with it the stamp of sufficiency. A site valued at eight thousand pounds, and forty thousand pounds in cash, have just been presented by Mr. Seney for providing in Brooklyn, New York, a hospital to be called the Methodist General Hospital. With a wise precision, too, the munificent donor insists that sickness and poverty shall entitle anyone to the benefits of the institution, be he Jew or Gentile, Protestant or Catholic, heathen or infidel, thereby recognising a fact too often forgotten by English charitable boards, that the divinest claim to aid is that put forth by the helpless and the sick. Certain metropolitan charities that have been figuring of late in a sectarian capacity would do well to emulate the generous New Yorkers' tolerant spirit.

THE importance of school hygiene has received practical recognition in Bern, where a petition is being numerously signed, the object of which is to invoke the aid of Government in carrying out the health reform in schools on which Prof. Vogt has long and eloquently insisted. The beneficial influence of cleanliness in school children is prominently urged, and that regular bathing of the whole body should be encouraged amongst the younger members of the population. Is it too much to hope that the common sense which dictates this demand will some time, ere long, find its way to British shores, and result in ridding our primary schools of the epidemic pestering stench that is the necessary accompaniment of unclean bodies?

WE understand that a third edition of Dr. Charteris's little *Students' Handbook of Medicine* is demanded. The first two editions have sold very rapidly, and it is evident that the book is a favourite one with students. Since Tanner's corresponding work has been enlarged, under the able editorship of the late Dr. Tilbury Fox, it has not commanded so good a sale. This fact is painfully significant of the abnormal requirements compressed in the brief period of study considered adequate for medical students, and the total inability of their possessing anything but the merest smattering of so-called medical science.

PRACTICAL science has sustained a serious loss by the death of Mr. E. R. Alston, a secretary of the Linnean Society, and well known as an energetic and enthusiastic naturalist, one of the few who carried his love of the subject to the length of practically following it out. Mr. Alston was only thirty-five years old, and had just lately completed the section "Mammals" in Salvini and Godman's work on the fauna and flora of Central America, the "Biologia Centrali Americana."

\* \*

NEW BOOKS AND NEW EDITIONS.—The following have been received for review since the publication of our last list Feb. 23rd. "The Vivisection Prize Essays." By Dr. Macanlay and others. "Fasting and Feeding Psychologically Considered." By L. S. Forbes Winslow, M.D. "Dysmenorrhoea." By Heywood Smith, M.D. "What every Mother should Know." By Edward Ellis, M.D. "The Collected Works of Francis Sibson, M.D." Edited by W. Miller Ord, M.D. "Transactions of Obstetrical Society of London for 1880." Vol. XXII.

## Correspondence.

### THE DUALITY OF THE CHANCRE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Dr. Dowse, in a letter contained in your issue of March 23, disagrees with me in my allegation that the soft sore has nothing to do with the causation of syphilis. He says that for *three years* he made observations at his hospital, which convinced him that syphilis occurred after, and in consequence of, the soft sore, as well as after the hard or non-suppurating sore. I can only say I would be glad to hear what these observations were. I heard Mr. Lawson, a few days ago, narrate to the Committee on the Contagious Diseases Acts somewhat similar experiences; but I must say his narrative failed to give me much information.

At this moment in Paris it is the custom at the Hôpital du Midi and Lourcine, and indeed in all the French hospitals, to make a separate entry for soft sores and "hard sores" or primary syphilis. Fournier, Diday, Ricord, Henry Lee, Berkeley Hill, and almost every writer of note adopts the dualistic theory. Mr. Lee was, indeed, examined on this point before the Contagious Diseases Acts Commission about a week ago, and then alleged that the *whols weight of Continental authority* was on the side of dualism, or the entire separation of the "soft sore" from syphilis—"They no longer discuss that point."

Professor Danielsen, of Christiania, inoculated many lepers with soft sore-pus and nothing took place, until, on one occasion, the secretion from a primary syphilitic sore was taken, when syphilis was produced in the leper patient. The "soft sore" has no incubation, for in twelve hours it may be seen commencing, when looked at with a lens: the hard sore, when inoculated on a subject, for experiment, has an incubation of from ten days to two months. I could go on differentiating the two sores much longer; but surely, this will suffice. Soft sores, I repeat, have nothing whatever to do with syphilis.

I am, yours, &c.,

17 Woburn Place, W.C. CHAS. R. DRYSDALE, M.D.  
March 23, 1881.

### STIMULANTS IN WORKHOUSES — ALCOHOLIC LIQUORS AS MEDICINES FOR THE SICK.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In your issue of March 16th there appears an article on "Stimulants in Workhouses, &c.," by Norman Kerr, M.D., F.L.S., London, in which the writer purports to give a return showing the "daily average number of persons relieved in workhouses during the year 1871; the cost of wine, ale, and spirits in each union, with the average cost per head on the number relieved, &c."

In this return Thurles Union is quoted, with 235 inmates, at an average cost for stimulants of 12s. 8d., making a total expenditure of £147 8s. 3d. This return astonished me much, as I am not in the habit of indulging my patients with stimulants to please their desire for them, but ad-

minister them medicinally. I therefore took the trouble of examining the books for 1871, and the result of my search shows that instead of £147 8s. 3d., there was only £22 19s. 2d. expended on stimulants for the year, giving an average of 1s. 11<sup>2</sup>/<sub>3</sub>d. for each inmate of the house.

How such a gross mistake could have occurred is a mystery to me.

Yours truly,

J. RUSSELL, Med. Officer,  
Thurles Union.

Thurles, 26th March, 1881.

[Having referred our correspondent's letter to Dr. Norman Kerr, we append his explanation of the apparent discrepancy:—"The 12s. 8d. quoted is a clerical error for 2s. 8d., which is the cost per head at both Lisnaskea and Thurles. The position of these unions between the 2s. 7d. of Castleblaney and Kilkee and the 2s. 9d. of Castlederg is proof of this. The return is quoted from the *Leinster Express*, and shows the amount spent on stimulants for the year ending Sept. 30th, 1871, as having been £31 19s. 11d.]

## Medico-Parliamentary.

### HOUSE OF COMMONS—FRIDAY, MARCH 25TH.

#### HOSPITAL MANAGEMENT.

MR. DODSON, in reply to Mr. J. Talbot, said he was aware of a charge having been made at a public meeting against the managers of the Metropolitan Asylum District of negligence in the management of the Small Pox Hospital at Fulham, in permitting nurses to go about the streets in their working dresses; that the charge was made in a letter by a gentleman who said he saw them, but that he had since admitted he was in error; that the letter was read at a public meeting; that he, (Mr. Dodson) regretted that the same publicity had not been given to the retraction as was given to the accusation.

MR. FIRTH, as chairman of the meeting in question, said there had not been an opportunity of making publicly the explanation suggested; but he should be glad to form a meeting for the purpose if the right hon. gentleman would attend and explain what was regarded as the inexplicable conduct of the Metropolitan Asylums Board.

#### SCARLET FEVER IN THE METROPOLIS.

MR. R. YORKE asked the President of the Local Government Board whether, having regard to the statements made to him by a deputation on the 21st instant on the subject of the prevalence of scarlet fever in the metropolis, and the increase of centres of infection, owing to the absence of all provision for the reception of convalescents from that infectious and dangerous disorder, he would give this urgent question his immediate attention; whether it was the duty of the Local Government Board to make provision for the establishment of convalescent homes in connection with the fever hospitals of the Metropolitan Asylums Board; and whether the existing state of the law admitted of this being done efficiently; and if it did not, whether he would take immediate steps to obtain by legislation the necessary powers.

MR. DODSON said he would not fail to give his attention to the subject, but it was no part of the duty of the Local Government Board to establish convalescent homes in connection with the fever hospitals of the Metropolis. Assuming, however, that such convalescent homes would be a complement of the hospitals, the Board would have discretionary power with respect to them. With regard to the action taken with respect to some other hospitals in the metropolis, he did not think the Board would meet with very much encouragement in endeavouring to make the provision referred to.

Indian Medical Service.—The following is a list of successful candidates at the competitive examination held 14th February at the University of London:—

- |                      |                      |
|----------------------|----------------------|
| 1. H. I. Griffiths.  | 12. M. B. Braganza.  |
| 2. F. D. C. Hawkins. | 13. H. W. Stevenson. |
| 3. A. Milne.         | 14. W. A. Corkery.   |
| 4. I. A. Cunningham. | 15. A. J. S. Patch.  |
| 5. A. G. E. Newland. | 16. E. Ross.         |
| 6. H. C. Hudson.     | 17. S. T. Rivetoom.  |
| 7. P. Mullane.       | 18. C. A. Adams.     |
| 8. A. Silcock.       | 19. J. F. MacLaren.  |
| 9. E. J. Baker.      | 20. J. B. Kanga.     |
| 10. J. W. Rodgers.   | 21. E. B. Da Costa.  |
| 11. E. G. Cooper.    | 22. A. J. O'Hara.    |

## NOTICES TO CORRESPONDENTS.

**AN EXTRAORDINARY TELESCOPE.**—We understand that Sir Henry Bessemer has almost completed the construction, at his house at Denmark Hill, of a telescope at which he has been working for nearly two years. The instrument will be of such power that he expects to be able by means of it to read a newspaper placed against the side of the Crystal Palace, 3½ miles distant.

**DR. RUATA (Padora).**—We have no copies of the *Gazetta Medica* by us, or we should be most happy to send them to the address given.

**ENQUIRER.**—Black Haw (*Viburnum prunifolium*) has had a reputation as an astringent for some time; it is now claimed to be anti-abortive and anti-spasmodic. Dose of fluid extract, 3ss.

**MR. GRAYSON MADDERS.**—Unsuitable for our columns.

**STATISTICS OF RECRUITING.**—The following notes gleaned from the annual Report of the Inspector-General on recruiting just issued will be of interest to army medical officers and others who take an interest in military matters. The number of recruits who joined the service during 1880 was 25,922. This was a slight diminution when compared with the number raised in 1879. The report states that the average physical qualities of the recruits offering themselves for enlistment have been improving annually. The reports on the recruits actually enlisted have also been more and more favourable each year, and the return on the 1st January, 1880, of the average physical condition of the soldiers serving in the army shows the following marked improvement; the proportion of soldiers under twenty years of age has fallen from 190 per 1,000 in 1871 to 100 per 1,000 in 1880. Also the proportion under 35 inches chest measurement has fallen from 291 per 1,000 in 1874 to 159 per 1,000 in 1880. The standard of height was reduced in 1880, to 5 feet 5 inches; whereas, in 1874, out of 10,000 recruits examined, 4,431 were under 5 feet 6 inches, in 1879 only 3,020 were under that height. A similar comparison in respect to weight gives 4,341 under 150lbs. in the former year, and only 3,737 in 1879. It follows from this that the average physical qualities of the recruits have been improving annually. It must, however, be remembered that we purchase this improved physique of the army at the expense of rejecting annually a much higher percentage of the men who offer themselves as recruits. The number of desertions in 1880 was 4,841, of whom 1,557 rejoined, showing a net loss by desertion of 3,284. The number of men discharged for misconduct was 1,877. As to the classes that furnish our soldiers, comparing 1874 with 1879, we find fewer labourers— from 619 per 1,000 to 594; more mechanics—from 176 to 198, whose handwork is greatly desired in the Army; and more shopmen and clerks—from 57 to 81. In 1876, out of 1,000 recruits, 719 were able to read and write, and 168 were unable to read; in 1879 the numbers were 761 and 189 respectively; while those who had enjoyed a superior education rose from 187 in 1872 to 678 per 1,000 on the 1st of January, 1880. The diminution of the illiterate is not great; there has, however, as yet been scarcely sufficient time to apply a test in this respect as a result of compulsory education. The relation of these conditions to the rates of sickness and mortality in the Army is important, and it will be interesting to observe how far the present very high rates of non-efficiency by these combined causes may hereafter be diminished.

**DR. DE SOUZA GUIMARAENS.**—The "Extraordinary proceeding of the Royal Microscopical Society" will be found in our columns for Feb. 23.

**DR. DUKE.**—The request will be attended to.

**MR. BANQUETTE** will find the subject exhaustively treated in our "Reports on the Bottled Waters of Europe" now appearing in the Journal.

**DR. J. MAGEE FINNY.**—Concluding portion of your "Lecture on Herpes" received, proof will be sent in due course.

**DR. THORWOOD.**—Received with thanks.

**ENQUIRER** should read the interesting paper in the April number of the *Medical Temperance Journal* by Dr. Alfred Carpenter side by side with the papers in the *Medical Press* by Dr. Norman Kerr.

OUR attention has been called to the following advertisement cut from half-a-column of shopkeeper's "cards" in the *Coleraine Chronicle*:

## CARD.

**W. H. CALDWELL, M.D., M.Ch., L.M.,**  
**HAS NOW COMMENCED PRACTICE**  
in COLERAINE.  
Residence and Consulting Rooms opposite  
Mr. STEWART HUNTER'S Establishment,  
Bridge Street.

As we cannot find this gentleman's name in the Medical Register for 1881, nor in any of the medical directories, we presume that he must be very recently qualified, and, therefore, unacquainted with what is expected in the way of professional respectability from Irish medical practitioners. We venture to remind him that members of our profession do not improve either their social or monetary position in Ireland by putting themselves in the same category as the local huxter or the advertising dentist.—ED. M. P. & C.

**DR. BERNARD KELLY.**—The emendation shall be made in the paper before it appears in print.

**ROYAL COLLEGE OF PHYSICIANS OF LONDON.**—Wednesday, March 30, at 5 p.m., Croonian Lectures: Dr. Moxon, "On the Influence of the Circulation upon the Nervous System."

**OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.**—Thursday, March 31, at 8 p.m., Living Specimen.—Mr. Sebastian Wilkinson, "On a Case of Retinal Hemorrhage."—8.30 p.m. Adjourned Discussion on the Relation of Optic Neuritis to Intercranial Disease. Dr. Stephen Mackenzie, Mr. Hutchinson, Mr. Couper, Dr. Gowers, Mr. Nettleship, Dr. Walter Edmunds, Dr. Buzzard, Dr. Bralley, and others are expected to speak.

**ROYAL COLLEGE OF PHYSICIANS OF LONDON.**—Friday, April 1, at 5 p.m., Lumleian Lectures: Dr. Southey, "On Bright's Disease."

**ROYAL INSTITUTION.**—Tuesday, April 5, at 8 .m., Prof. Schäfer, "On the Blood."

**HARVEIAN SOCIETY OF LONDON.**—Thursday, April 7, at 8.30 p.m., "Fibrous Polypus of the Uterus," by Dr. T. C. Hayes.—"The Treatment of Empyema," by Dr. Chesdale.

**CLINICAL SOCIETY OF LONDON.**—Friday, April 8, at 8 o'clock, Dr. B. O'Connor, "A Case of Syphilitic Psoriasis."—Mr. Eushton Parker, "A Case of Arterial Hematoma of the Forearm."—Dr. Stevenson, "A Case of Meningocele" (Patient will be shown).—Mr. J. H. Morgan, "A Case of Progressive Painful Inflammation of the Arteries."  
D. H. CULLMORE, F.R.C.S.I.—In our next.

## VACANCIES.

**Aberdeen.**—Medical Officer of Health for the City. Salary, £300. Applications to be lodged with the Town Clerk before April 9.

**Birmingham Lunatic Asylum.**—Assistant Medical Officer. Salary, £150, with board. Applications to the Medical Superintendent before April 2.

**Bournemouth General Dispensary.**—Resident Medical Officer. Salary, £120. Applications to the Treasurer before April 2.

**Carrickmacross Union, Donaghmoyny Dispensary.**—Medical Officer. Salary, £100 per annum, and £15 as Medical Officer of Health. Election, April 11.

**Dundalk Union, Barronstown Dispensary.**—Medical Officer. Salary, £120 per annum, and £25 as Medical Officer of Health. Election, April 7.

**Poplar Hospital for Accidents.**—House Surgeon. Salary commencing at £100, with board. Applications to the Hon. Sec., W. H. Beaumont, Rosherville, Kent.

**Royal Westminster Ophthalmic Hospital.**—Two Assistant Surgeons on the Staff; must hold the F.R.C.S. Applications to the Committee of Management before March 31. (See Advt.)

**Sunderland Infirmary.**—Two House Surgeons. Salary commencing at £30 and £60 respectively, with board. Applications to the Chairman of the Medical Board before May 4.

**West Sussex Infirmary, Chichester.**—House Surgeon and Secretary. Salary, £100, with board. Applications to the Secretary before April 9.

## APPOINTMENTS.

**BEVAN, W. LI., M.B., C.M.,** House Surgeon to the Dorset County Hospital.

**BREBETON, J. B., L.K.Q.C.P.I., L.R.C.S.I.,** Medical Officer for the First District of the Bodmin Union.

**CAWTHORNE, B. W., M.B., C.M.,** Medical Officer for the Fifth District of the Stroud Union.

**DAVIS, Dr.** Medical Officer to the Colton Dispensary, Ardes Union.

**EDWARDS, D. T., M.R.C.S.E.,** Medical Officer of the Pentrich District of the Cardiff Union.

**ENGLISH, Mr. E.,** House Surgeon to the London Hospital.

**JOHNSTON, H. M., M.D., L.R.C.S.I.,** Medical Officer to the Stranorlar Union Workhouse and Fever Hospital.

**KEMMIS, H. M., L.K.Q.C.P.I., M.R.C.S.E.,** Medical Officer for the First District of the Bridgewater Union.

**O'DONAGHUE, P., L.K.Q.C.P.I., L.R.C.P.Ed.,** Medical Officer to the Hospital of the Loughrea Union.

**ORFEUR, C. H.,** Medical Officer for the Nailsea and Wraxall District of the Bedminster Union.

**PATTON, W. J., B.A., M.B., L.R.C.S.I.,** Assistant Medical Officer to the Three Counties Asylum.

**SMITH, J., M.R.C.S.E.,** Medical Officer of Health to the Rural Sanitary Authority, Guildford Union.

**STEELE, W. C., L.R.C.P.Ed., M.R.C.S.E.,** Medical Officer to the Newington Infirmary, Walworth.

**WOOD, E. J., M.B., M.R.C.S.E.,** Medical Officer for the Third District of the Maidstone Union.

## Births.

**DAWSON.**—March 24, at 28 Hyde Park Street, London, W., the wife of Yelverton Dawson, M.D., of a daughter.

**PALMER.**—March 26, at 51 Waterloo, Northampton, the wife of John Richard Palmer, L.K. & Q.C.P.I., & L.R.C.S.I., of a daughter.

**SALE.**—March 26, at 43 Harcourt Street, Dublin, the wife of Dr. Gregory Sale, of Newpark, co. Kildare, of a daughter.

**WALLACE.**—March 21, at Cleckheaton, Yorks, the wife of Edward J. Wallace, M.D., of a son.

## Marriages.

**NESBITT-GRESHAM.**—March 23, at Derrylin, co. Fermanagh, Dawson Nesbitt, M.D., to Emily, youngest daughter of the late W. H. Gresham, Esq., of Glenwood Luan, co. Dublin.

**THOM-AITKEN.**—March 24, at Oaklands, Crief, Alex. Thom, M.A., M.B., son of Dr. Thom, of Crief, to Helen, elder daughter of Mark Aitken, of Oaklands.

## Deaths.

**DANIELL.**—March 23, at 20 Cathcart Road, South Kensington, S.W., Sarah, wife of Richard T. Daniell, M.B., F.R.C.S.I.

**DAVIES.**—March 13, at Nice, Albert Davies, M.D., late of Maidstone, Kent.

**ELLIS.**—March 19, at his residence, Tower Street, Hackney, and late of Sudbrook Park, James Ellis, M.D., aged 77.

**FORBES.**—March 20, at Queen Street, Edinburgh, Geo. Feddes Forbes, Surgeon-Major, H.M. Indian Army.

**JENKS.**—March 20, at 18, Circus, Bath, Eliza, wife of G. S. Jenks, M.D.

**LEVYCK.**—March 23, at West Ham, Essex, George Levick, M.R.C.S.E., in his 40th year.

## Original Communications.

### THE LUMLEIAN LECTURES ON BRIGHT'S DISEASE.

Delivered before the Royal College of Physicians, London.

LECTURE I.—PART I.—Delivered APRIL 1ST.

By REGINALD SOUTHEY, M.D. Oxon., F.R.C.P. Lond., Physician to St. Bartholomew's Hospital.

To-DAY, sir, I shall attempt to place before you an historical and critical review of what has been written on the subject of renal dropsy. I hope to be able to show that our knowledge of those diseases of the kidneys which long have been, and as I believe long will be, associated with Bright's name, has been steadily progressing, but is still far from being complete.

The pathology of renal disease has been a much vexed problem, teeming with dispute and controversy. Men wax as hot over it as they did over tubercle, and each writer is confident that his own doxy alone can be orthodox. I have endeavoured to educate myself up to the standard of being a fair critic, and since, in my opinion, the time has arrived when we may profitably take stock, as it were, of facts and theories that have been laid up, I have hailed the opportunity to-day, presented by my appointment as your Lumleian lecturer, to do so. The preacher of old (Eccles. chap. I., v. 10), a man who gave his heart to seek and search out all kings, and who found out the vanity of most kings, wrote, "Is there anything whereof it may be said, see, this is new? It hath been already of old time which was before us."

Bright was not the discoverer of renal disease; no, nor of albumen in the urine associated with it, nor of the dropsy, nor of the death tendencies, nor of the small granular kidney. But he advanced our knowledge upon all these things by his remarkable clinical ability and clear judgment in a manner which has made posterity respect his work, and desire to perpetuate his name.

Hippocrates, in his *Frognostics* (21) distinguishes the

dropsies originating from the flanks or loins from those which are due to disease of the liver; and although, in his description of the diseases of the kidneys, we find nothing to prove that he was acquainted with any pathological condition other than those which are provoked by gravel, calculus, or by extensions of mischief from the bladder up into the kidney, it is obvious, from remarks found scattered through his writings, that he had not failed to observe diminished urination associated with general dropsy, beginning in the feet, and attended by obstinate diarrhoea, that failed to relieve or empty the abdomen.

In Section 7, Aphorism 84, we read: Bubbles maintained upon the top of the urine signify a disease of the reins, and likewise its long continuance; a fact which remained unimportant until the end of the last century, when it was ascertained that albuminous urine held a froth of bubbles on its surface.

Aretæus the Cappadocian (Adams's edition, London, 1856, p. 342) makes some observations upon blood in the urine which, interpreted by our present knowledge (and although vague and rather spoiled by being mixed up with remarks on hamorrhoids), show at all events that he recognised the association of pallor, sluggishness, proclivity to headache, and epileptic attacks, in some forms of urinary disease, as well as general anasarca and dropsy in others. It is probable that Aretæus was a contemporary of Galen, which takes us back, therefore, to the certain date, A.D. 131.

Towards the close of the sixteenth century, necropsis became more frequent; and several medical authors make mention of dropsy in connection with abnormal conditions of the kidneys.

J. B. Morgagni, Epistle 42, "De Sedibus et Causis Morborum," describes the case of a dropsical patient who died suddenly, and whose body he examined. In Epistle 41, art. 4, he notices a case of acute renal dropsy, provoked doubtless by exposure of the body to cold in the treatment of some skin eruption. Morgagni writes: "The kidneys were larger than normal." The itch was treated by an ointment rubbed into the skin; suppression of urine and vomiting followed, pain in the left lumbar region, general dropsy, and death. Granular kidneys and large white kidneys had therefore been discovered before Bright wrote: while Avicenna, in 1164, was certainly before him in distinguishing between the dropsies consequent upon disease of the liver, and those which followed upon disease of the kidney.

It is to Cotugno, however, in 1770 ("De Ichiade Ner-

vosâ Comment." Vienna, p. 24-25), that we are indebted for the discovery of albumen in the urine of dropsical persons, which he attributed to the passage of the dropsical effusion over into the urine, and regarded unfortunately most incorrectly, as Nature's mode of resisting and repairing disease.

Wells, whose "Observations on the Dropsy which succeeds Scarlet Fever," were published in the "Transactions of a Society for the Improvement of Medical and Chirurgical Knowledge," vol. iii., pp. 16 and 194, may be fairly regarded as the pioneer who probably guided Dr. R. Bright to his clinical investigations upon the connection between renal disease and dropsy. Wells it was who pointed out that the urine after scarlet fever contained both blood-colouring matter and blood-serum; and that, even when scarcely abnormal in aspect at all, it might contain sero-albumen, recognisable by its coagulability both with heat and nitric acid. Out of 138 cases of dropsy after scarlet fever, he discovered serum, as he rightly enough calls it, in the large proportion of seventy-eight times; and, later on, pursuing his inquiries further, Dr. Wells observed that other cases of general anasarca were associated with renal disease and coagulable urine. He seems, too, to have completely forestalled Dr. Bright in his analysis of the clinical symptoms, having observed that in this variety of dropsy sharp pains in the loins and limbs sometimes preceded as well as attended the dropsy, and that the pulse, far from signifying general weakness, was often full and frequent. The case recorded by Wells, of a soldier, æt. 47, who died of dropsy, complicated finally by an inflammation of the lung, whose kidneys he found harder than normal, their cortical parts being thickened, and structures generally altered by deposits of coagulable lymph through their substance, is probably the first distinctly diagnosed case during life of chronic renal disease. Wells' work in this direction was eminently philosophical. He discovered albumen first in the urine of post-scarlatinal dropsy; afterwards in the urine voided in other species of dropsy connected with pathological states of kidney; then he examined the urine of persons in apparent health; and again occasionally lit upon the presence of albumen in it. He ascertained that blood-serum was discoverable in the urine in many forms of chronic as well as of acute disease; and discovered it once in the urine of a person who enjoyed the aspect of health, but who subsequently died dropsical.

In 1813, John Blackall published a volume, "Observations on the Nature and Cure of Dropsy," which ran through several subsequent editions. The most frequent cases of renal dropsy, which he records, were the forms following scarlet fever, and the cases of acute diffuse nephritis determined by exposure to cold and wet in persons who were pursuing a course of mercury. He surmised, but failed to prove, that the normal amounts of urea were retained in the system in these cases; and, although he made out that the kidneys were diseased in an unusual proportion of the cases, he was evidently biased by the various other inflammatory lesions, of which, as he writes, "the whole system bears the greatest marks;" and attributed the affection less to the kidney-lesion than Wells had done, and more to a wide-spread inflammatory general disposition. This theory of his led him to recommend free blood-letting and depletory treatment.

Dr. Scudamore, in his treatise on "Gout," published in 1823, insisted on the clinical and prognostic importance of albumen occasionally found in the urine of dyspeptic and gouty subjects, and noticed that these persons were of a peculiar nervous habit, and micturated frequently. More than this, he pointed out that, although no dropsy attended on these symptoms, the urine departed from a normal standard not only in containing albumen, but by holding less urea, less uric acid, and less salts altogether than it should do. It was an imperfect secretion, he wrote.

M. Andral, in 1826, published in his "Clinique Médicale," tome iii., p. 567, a case of dropsy without affection of the heart or peritoneum, in which the kidneys were the sole organs diseased. His description of these granular kidneys is very precise. Thus, he writes, the external cortical substance, and a part of the tubular (*i.e.*, medullary) portion, consisted chiefly of white granular tissue, and appeared divided up into little masses or grains which stood out distinct from the natural red tissue of the kidney. The death-cause in this case was double hydro-thorax; but this he referred to the original or primary renal lesion.

In 1827, Dr. Bright published his "Reports on Medical

Cases;" and in the same year, and probably entirely uninfluenced by his writings, M. Barbier, of Amiens, published in Paris his "Précis de Nosologie et de Thérapeutique," in vol. i., p. 410, in which he describes (Bright's) small granular kidney as a fact well known to him, writing: "On rencontre souvent les reins d'une petitesse remarquable; leur volume réduit au tiers on un quart de qu'il devrait être." He calls the affection "oligotrophie," and adds: "La sécrétion urinaire est toujours (?) notablement diminuée, il survient souvent un œdème général." He gives the case of an old woman in the Hôtel Dieu as an illustration of this affection, and notices that, with the exception of a heart "légèrement dilaté, les autres appareils étaient en bon état." A sudden pleurisy was also the final cause of death here. At p. 553, we find a chapter with the heading "Sclérisie des Reins," in which he shows his intimate acquaintance with this affection in its late stages, and its relation, as a cause, often overlooked, of a rebellious form of anasarca, in which the blood-serum had a more milky colour than was normal—leuco-phlegmasia with kidney-sclerosis.

Dr. Richard Bright's first publication appeared in 1827; it had been led up to, as all great epochs in the history of medicine have been, by study as well as clinical observation. Blackall and Wells had already established the importance of albumen in the urine as a symptom of dropsy. The distinguishing feature of Bright's volume is its careful reasoning and its modest inferences from facts, put forward after patient investigation of them. He heads the first chapter very tentatively, "Cases Illustrative of some of the Appearances on the Examination of Diseases terminating in Dropsical Effusion." The cases are narrated, the clinical symptoms described, and the post-mortem appearances dwelt on. The connection of diseased kidney with certain dropsies is pointed out; and the alterations in the structure of the kidneys found in the bodies of those whose deaths had been preceded by dropsy and albuminuria are sketched by a masterly hand. He distinguishes (as Hippocrates had done some 2,000 years before him) a dropsy in which the kidney is found diseased from a dropsy in which the liver is diseased; but he is far too cautious to advance to inferences unjustified by the facts before him, to talk of renal dropsy or primary renal disease as the cause of dropsy. He speaks of the coincidences—the associated facts. By him, in the first instance, the structural changes in the kidney are attributed to certain injurious influences which, acting on the stomach or the skin, disturb the renal functions, either by disordering the circulation through the kidneys, or bringing about a state of decided inflammation in them. Further on, he writes: "He thinks his observations almost authorize him to establish three varieties, if not three completely separate forms, of diseased structure; but he does not pin himself down to these three typical forms. He thought his third form might be an advanced stage of the same essential process which produced the second; and he distinctly notices other conditions of kidney—a pre-renal softness of the organ, associated with similar flabbiness of the liver, spleen, and heart, as a pathological condition which led to albuminuria; and describes a separate category of cases, in which the kidneys were firmer than is normal, and where the tubules are blocked up.

I wish to point attention to his cautiousness in making varieties, and to the conciseness with which he attributes the renal structural changes to widespread influences, which, acting either through the stomach or the skin, disordered the renal circulation and its functions.

After all the work that has been expended in the closer investigation of the minute anatomy of the different diseases of the kidneys, and all the clinical observations which have been published in the last fifty-four years upon the same subject, the questions whether there be one or more varieties of diffuse renal disease, and what is the real first cause of the renal degenerations to which he called special attention, remain much where he left them.

The writers who followed Bright, amongst whom in England the most eminent were Christison, James Gregory, Osborne, Copland, Elliotson, Graves, and Willis, added clinical information of no inconsiderable value; but some of them busied themselves over-much in controversy upon the etiology of the new disease, and neglected investigating the nature of its pathology. Thus we find doctors differing very early, and ranging themselves in two hostile camps; the one as humoro-pathologists, teaching that the disease was general, and commenced in a vitiated state of the

blood, before ever the kidneys suffered; the others maintaining that the kidney-disease was primary, and led to the impairment and mal-constitution of the blood.

Dr. Bright, in the publication of his second volume, which appeared in 1831, having established upon irresistible evidence the coincidence of the three facts—dropsy, albuminuria, and special pathological changes of the kidneys—inferred that the renal lesion ought to be regarded as the first cause, or entity of the disease, and the dropsy and albuminuria as the consequences of it. Graves, Elliotson, and Copland thought the renal lesion was the part symptom only of a general blood disease.

Christison and James Gregory stood by Bright and regarded it as the primary lesion, and they further advanced our knowledge—Christison by careful clinical examination, both of urine and blood-serum, in various stages and varieties of renal disease. The discovery of urea in the blood, and several estimations of its quantity in renal dropsies, were made by him in some cases of albuminuria; and he was led to accept the idea—first put forward by MM. Prevost and Dumas, founded on experiments made by them in extirpating the kidneys of animals—that urea was not generated by the kidneys, but separated by them.

Christison proved to demonstration the low specific gravity of the serum of the blood that attached to chronic renal disease; confirmed the associated hypertrophy of the heart which Bright had noticed; discussed the essential and non-essential symptoms; showed that general anasarca, although a very frequent was no necessary symptom of diseased kidney; called attention to pulmonary catarrh, emphysema, hæmorrhagic apoplexy, as more frequent complications than inflammations of the serous membranes; and pointed out the tendency to death by coma and so-called serous apoplexy, so often discovered in these cases, when the necropsy presented congestion neither of the brain or of its membranes.

Dr. J. Gregory's observations on diseased kidney (*Edinburgh Medical Journal*, 1831, vol. xxxvi, p. 318), connected with albuminous urine, are quite as remarkable as Bright's work was. He fully recognised the fact that the urine might be albuminous in certain disordered states of the system, unconnected with any special pathological alterations of the kidneys. "But," he writes, "when the urine is coagulable, and at the same time decidedly low in density, and below the natural standard in quantity; and when this state of urine has existed for some time, in a more or less marked degree; and when it is accompanied by dropsical effusion, in some of its forms, particularly slight but obstinate œdema of the extremities and face; and when, in the absence of dropsy—by no means a constant symptom—there is intractable vomiting and diarrhoea, we have evidence of organic disease of the kidney, upon which we may rely with much confidence."

It was in 1838 that Dr. Robert Willis published a work on "Urinary Diseases and their Treatment." It was a work that deserved translation, and it was translated into German by Hensinger, and published at Eissnach in 1841.

In his book, reference is made more than once to Bright's disease, as a new discovery. Dr. Willis's book, read at the present time, offers little of interest regarding the diffuse diseases of the kidney; but there was a certain order about it that recommended it to book-writers; and it is probable that its appearance in Germany introduced Bright's observations to German readers, and stimulated many to read his clinical reports.

It was in 1838 also that Martin Solon published in Paris a work on "Albuminuria or Dropsy caused by a Disease of the Kidneys;" and to him in England we owe the vague general denomination of albuminuria for a variety of renal affections, some of which were, but many of which had no claim whatever, to be classed as the kidney disease which Bright had clinically portrayed.

M. Rayer's work, "Traité des Maladies des Reins," was not yet published, but the materials for it must have been forward in Rayer's hands, for as he himself writes, vol. ii, p. 666, "My first researches on renal disorders were begun in 1830."

As Rayer justly says, to group together, under the head of albuminuria, affections so different in nature and issue as M. Solon did, was practically useless. Albuminous urine is a symptom, not a pathological entity. Evidently there were not many passages-at-arms between M. Martin Solon

and M. Rayer at the Royal Academy of Medicine; the one maintaining his *néphrite-albumineuse*, with six different subforms; the other, his *albuminurie au premier, second et troisième degré*; or, 1. Sans lésion rénale; 2. Avec lésion rénale; 3. Avec hydropisie; 4. Avec les productions granuleuses du Bright; 5. Avec dégénération variée du tissu renal et productions accidentelles.

To Rayer, however, the thanks of all who study renal diseases must eternally attach, for a work quite unparalleled in the annals of medicine for research and clinical acumen. Its weakest part is just Bright's disease—the acute and chronic forms of diffuse nephritis—and here it falls short, because, at that time, neither the minute normal or pathological anatomy of the kidney had been much investigated in Europe.

Hitherto, the disputed points had been a primary renal or primary blood disorder; but now that the German observers—up to this date singularly indifferent to Bright's discovery—took up the matter, the nature of the renal lesion began to be closely sifted by the microscope. Was it an inflammatory process, a fatty degeneration, a steatosis, a fibrous degeneration, or fibrosis? Was it one disease from first to last, with various stages, or were there several distinct varieties, with each their own separate clinical history?

Passing over, as we may, with scant notice the early pathological observations of Gluge Valentin and Henle Vogel, Canstatt, and von Siebold, our attention is arrested by Reinhardt's work, published in the *Deutsche Klinik* (von Göschen), November 5th, 1849, who attached all the pathological states of kidney described by Bright, to inflammatory processes. He gave the name of diffuse inflammation to the changes in question, because the exudation poured out showed so little disposition to organise, and because it extended so widely through the affected organ. It was a croupous form of inflammation, because casts came away from the tubular structures; it was an inflammation that pursued various courses, according to the causes that induced it, and the individual it invaded; but he did not regard the various forms of kidney figured by Bright as the result of one single process of the disease, but of several successive invasions. Like every other inflammatory process, it might come under observation at different stages of hyperæmic congestion or of exudation, with fatty degeneration of epithelium of connective tissue new growth with ultimate scar tissue-like contraction.

It is not to be supposed that the professors of pathology in the Berlin and Vienna schools had overlooked conditions so obviously abnormal as the kidneys of Bright's disease presented. Rokitansky, in his text-book of "Pathological Anatomy," 1842, described eight forms of morbus Brightii, of which the lardaceous kidney was the last; but the clinical symptoms attaching to these were not understood for the minute anatomy of the kidney and physiology of the urine secretion, had been hitherto only imperfectly studied.

The first important step in advance was Mr. Bowman's philosophical paper on the Structure and Use of the Malpighian Bodies of the Kidney, which appeared in 1842 in the "Transactions" of the Royal Society, which described the minute anatomy of the organ with great care. From the facts before him, Mr. Bowman inferred that the glomerules separated the urine-water, and the secreting tubes and cells the urine-solids; and the situation of the tufts incorporated at the terminals or beginnings of the tubules, appointed them, as he thought, an apparatus contrived for washing the more solid secretion out of the renal epithelium. From thenceforth, the study of Bright's disease advanced, *pari passu*, with anatomical investigation and physiological experiment. To follow it step by step would require a longer review than we can afford to give, although we propose to glance briefly at some of the important stand-points, as these have been in succession reached.

For many years in England Bowman's views were accepted without a doubt, and may be certainly regarded as the foundation-stone upon which the English physicians and pathologists based their doctrines of renal disease. Bowman's idea that the tufts are the source of the urine-water I combated many years ago. It is, I believe, one source of the urinary-water, certainly not the sole source. The vasa recta are modified, Malpighian tufts and urine-water passes from them through and into the down-looping tubes.

In November 1845, Dr. G. Johnson communicated to the

"Medico-Chirurgical Transactions" his earliest communications on the Minute Anatomy and Pathology of Bright's Disease (*vide* vol. xxix, 1846). He found that the granulated or mottled aspect of the kidney, associated with albuminous urine and dropsy, was due to an inordinate amount of fat collected in the renal epithelial cells; and he reasoned, correctly enough, that such a distension and infarction of the tubules must encroach upon the intertubular capillary rooms, regard the circulation through these networks, and lead to engorgement of the Malpighian tufts. Fatty degeneration of the renal epithelium was, he thought, the commencement and essence of Bright's disease; effusion of blood and blood-serum in the urine was the result of abnormal blood-pressure, secondary to the tubulous infarction.

Even at this early period, Dr. Johnson distinctly taught that the kidneys described by Dr. Bright could not be accepted as different stages of the same disease. Bright's small red granular kidney had little in common with the large white smooth one; and, if the name of Bright's disease was to be retained for a renal degenerative process, which began and progressed by fatty metamorphoses, the white kidney must be separated from the atrophic organ.

Dr. Johnson's communication evoked a notable rejoinder from Dr. Quain, which appeared in the November *Lancet* for 1845, p. 594. Quain writes that "in more than fifty specimens of this disease examined by me, the fatty condition of the kidney was, in one instance only, sufficient to attract much attention." In the large proportion of cases, he found caco-plastic lymph, either in the form of nucleated cells, or of simple granular matter, or of a deposit that he observed assuming distinctly filamentous or fibrous characters.

Quain assigned the seat of the deposit to the parenchyma of the kidney, external to the tubes, and observed granular matter contained within the tubes themselves. He inferred that congestion preceded the deposits, and that the changes in dispute were from the first inflammatory.

Quain was the first to make three forms of kidney-disease the several outcomes of these different forms of deposit or exudation: 1. The simple enlarged mottled kidney; 2. The truly granular or atrophied kidney; 3. The large, flabby, fatty-looking kidney. Dr. Johnson's views on fatty degeneration received complete sifting and clear answer by Professor Virchow in his "Archiv," Band iv., s. 260 (1847), where the inflammatory nature of the initial changes in Bright's disease was clearly enunciated; who further distinguished between simple tubular catarrhal and parenchymatous inflammation, the former recovering completely without further hurt, the other having possible issue in interstitial or glandular hyperplasia.

(To be continued.)

## DR. GUY ON TEMPERATURE AND MORTALITY. (a)

On the 15th March Dr. Guy read a paper on this subject with the primary object of illustrating the use of tabular analysis in the discovery of truth. But, as the paper has a medical interest of its own, irrespective of this its primary object, we here give it with the necessary omission of certain tables and plans which will be doubtless published in an early number of the *Journal of the Statistical Society*.

It is now nearly forty years (May, 1843) since Dr. Guy tells us that he made an attempt to determine the influence of the seasons and weather on sickness and mortality here in London. Twenty years later, Dr. R. E. Scoresby-Jackson submitted to the Royal Society of Edinburgh an elaborate paper on the same subject, ingeniously illustrated by eight coloured circular diagrams. This paper is one that ought not to be passed over by any student of such matters who would know how industry intelligently directed can be made subservient to the discovery of truth. (b)

(a) On Temperature and its Relation to Mortality: an Illustration of the Application of the Numerical Method to the Discovery of Truth. By William A. Guy, M.B., Cantab., F.R.S., one of the Honorary Presidents of the Statistical Society.

(b) "Transactions of the Royal Society of Edinburgh," vol. xxiii, part ii.

But the works to which Dr. Guy called the attention of the Society were the well known quarto tract of the younger Heberden, published in the first year of this century, (a) and the learned production of Dr. Thomas Short, issued in the middle of the last century. (b)

What Heberden has to say on the subject of Dr. Guy's paper will be found from p. 46 to p. 59 of his work, under the heading of "The Weekly Table of Mortality." Dr. Guy begins by presenting us with Dr. Short's fifteenth table printed at p. 192, which he inserts rather than his eleventh table, because it comprises not the monthly number of deaths only, but also, the ages at which the deaths happened. As this table is the more simple table of the two, Dr. Guy begins by inserting the three columns of that table which throw most light on the subject of his paper. The entire table will be found at p. 176 of Dr. Short's work. It is headed, "Of the London Bills of Mortality Monthly for Fifteen Years, viz., from 1st January, 1732, to 1st January, 1747."

This table Dr. Guy calls a *table of Record or Reference*, and proceeds to inquire what steps we ought to take in order to convert it into a table of *Analysis or Discovery*. How shall we arrange these figures so that they may reveal to us some truth? At present they are all confusion. Let us try to put order into them.

The author assumes to begin with, that the figures of the table are such an approximation to the real numbers as fairly to represent what happened to a considerable number of the inhabitants of London in the aggregate of several successive years, about the middle of the eighteenth century.

The table, if we question it aright, will have something to reveal to us about the relation of the months and seasons of the year to the number of deaths, and of that which most distinctly characterises them—their temperature; for Dr. Guy assumes the greater influence of temperature on mortality, when compared with all other atmospheric conditions which can be measured and recorded by instruments, to be clearly established both by Heberden (to say nothing of earlier writers on the subject) and by Scoresby-Jackson. On the face of the table as it stands, the maximum mortality occurs in January (one of the winter months), and the minimum in July (a summer month), and that both for males and females. Is this because January is cold and July warm, for temperature is obviously the element in which the two months differ most? The way to find this out is to arrange the figures of the table by cold and hot months respectively.

But the months, like the weeks of which they consist, are but arbitrary divisions of time, and so are the seasons. May we not substitute for our seasons something more in accordance with the nature of things? That which we call *winter* in our climate does not embrace all the coldest months, nor that which we call *summer* all the hottest; and *spring*, which resembles *autumn* in the medium character of its temperature, is separated from it by the four warmest months. The vulgar division of the year into four quarters of three months each (first quarter, January, February, March; second quarter, April, May, June; third quarter, July, August, September; fourth quarter, October, November, December), does not readily lend itself to a scientific treatment of the relations existing between the two obviously allied conditions, temperature and mortality. For between the average temperature of January, February, and March, and the average temperature of October, November, and December, the difference is less than 2 degrees (1.9). We clearly improve on this division of the year when we substitute for it four groups of three months each, making December, January, and

(a) "Observations on the Increase and Decrease of different Diseases, and particularly of the Plague." By William Heberden, jun., M.D., F.R.S. 1801. 4to.

(b) "New Observations, Natural, Moral, Civil, Political, and Medical, on City, Town, and Country Bills of Mortality. To which are added Large and Clear Abstracts of the best Authors who have wrote on that subject; with an Appendix on the Weather and Meteors." By Thomas Short, M.D. 1750. 8vo.

February to stand for *winter*; March, April, and May for *spring*; June, July, and August for *summer*; and September, October, and November for *autumn*.

On striking an average of the five years 1838-42, the superiority of seasons over quarters, when temperature is the element to be inquired into, is very obvious. The differences between season and season are very much more evenly, and therefore much more conveniently, distributed; for between the winter and summer temperature there is an average difference of nearly 25 degrees (24·7 deg.), such a difference as may be expected to make itself felt in the record of deaths. This difference is also in excess of that between the first and third quarter by 5·5 degrees.

But there is a better division of the year than either of the foregoing—a division into three periods of four months each; the four hottest months being June, July, August, and September; the four coldest, December, January, February, and March; and the four temperate, April, May, October, and November. This division has one or two obvious advantages. In the first place, it creates for comparison two extremes and an average. In the second place it necessitates only one act of rectification, and that only needed when we are not dealing with a leap year. The temperate and the hot months consist each of 122 days, and so do the cold months in leap year. In other years, the three periods are made of equal length by adding to the four cold months the fraction 1-121.

The average temperatures of these three divisions are as follows:—Four coldest months, 40·0; four temperate months, 49·4; four hottest months, 62·3; the difference between the four coldest and four temperate months being 9·4, and between the four temperate and four hottest months, 12·9, making the difference between the four coldest and four hottest months, 22·3.

By this arrangement, too, the average temperature of the four cold months (40·0 deg.) is widely separated from that of the four hot months (62·3 deg.).

By now converting this table of *Record and Reference* into a table of *Analysis and Discovery*, that is to say, by grouping its figures in accordance with the three-fold division, the higher mortality incident to the four cold months of the year as compared with the four hot months, both in males and females, is brought into distinct relief. The intermediate position of the four temperate months is made equally manifest; so that, without any need of rectification of the figures of the first four months, we arrive at the conclusion that the death-rate is greatly in excess in the cold season of the year. A simple calculation shows that if 55 in 100 die in the colder months, only 45 die in the warmer. Among individual months, January shows the highest figure, and July the lowest. The figures for the two sexes taken together are:—winter, 138,182; temperate months, 125,634; summer, 114,019.

These figures, then, afford a complete justification of Heberden's first proposition, that "the whole number of deaths is the greatest in January, February, and March, and least in June, July, and August." This was true of the early part of the eighteenth century here in London. It may not have been true in Greece or Italy, or even in England, in earlier periods of its history, but we know it to be true of the England of to-day. Nor is it true only of the London of the early part of the eighteenth century, for Heberden appeals to Dr. Short's registers of five-and-twenty different country towns in England in proof that the death-rate follows the same rule in the provinces as in the metropolis; and Woolcombe (a) embodies in one table, at the end of his work, the results obtained for no less than thirteen different countries, cities, towns, and groups of towns. In every case the ratio per cent. of the mortality in winter exceeds the ratio in summer. In the

case of Eccles, near Manchester, it is as small as 4, and so it is in Sweden. But in London it is 8, and at Plymouth as many as 18.

In the whole series of facts there is not a single exception to the rule that winter is more fatal to life than summer, though the winter mortality ranges from the low figure of 52 per cent. to the high figure of 59.

The high mortality of the winter months may, therefore, be taken as a fact placed beyond the reach of doubt; but we have yet to consider the larger question of the relative position, in respect of temperature and mortality, of the three groups of four months each, including the four temperate months.

The three aggregates of burials for the three cold, temperate, and hot sections of the year, as deduced from the table which Heberden gives at p. 48, are 66,357; 61,991; and 52,508. Here we have the same order as above; but the maximum monthly mortality is shifted from January to March and April, and the minimum to August and September. So also with the seven years' register of burials of the city of York, published by Dr. White, and quoted by Heberden at p. 49. The four cold months figure for 1,210 deaths, the four temperate for 1,009, and the four hot months for 956; while the months of January and July resume their places at the top and bottom of the monthly return of deaths.

Six tables given by Dr. Price, in his celebrated essay on "Reversionary Payments," when April and May and October and November are thrown together as the four temperate months, result in similar figures.

Though Sweden and Stockholm show a slight excess of deaths in the four temperate months over those of the four cold months, and one out of the four English towns (Eccles) is an exception to the rule, which places the cold and hot months at the two extremes of mortality, and the four temperate months in the intermediate position, with the one exception of Stockholm, the mortality of the winter months largely exceeds that of the summer.

The same order of the four quarters of the year prevailed, as Heberden tells us, at Edinburgh and Paris, and throughout Sweden.

But at Marseilles and Montpellier a wholly different state of things prevailed, as Heberden shows by a table also inserted at page 49. In lieu of the death-rate varying as the temperature, the four cold months displaying the highest, and the four hot months the lowest, mortality, the figures stand thus:—June, July, August, September—Marseilles, 6,920; Montpellier, 4,021. December, January, February, March—Marseilles, 6,781; Montpellier, 3,363. April, May, October, November—Marseilles, 6,618; Montpellier, 2,960.

If, as is probably the case, the three groups of four months correspond in these southern districts of France to the coldest, hottest, and temperate divisions of the year, we have them ranged in the same order in either place, namely, the four hot, the four cold, and the four temperate months, so that if we mark the four months of greatest mortality by the figure 3, the four months or least mortality by the figure 1, and the four months of intermediate mortality by the figure 2, we shall have the following contrast:—England, Sweden, Edinburgh, and Paris—Cold, 3; hot, 1; temperate, 2. Marseilles and Montpellier—Cold, 2; hot, 3; temperate, 1.

These figures give us good reason to believe that the order of the seasons, as it prevails in the more temperate climates, does not obtain in warmer countries; and it is likely that the Roman physician Celsus had reference to the warmer parts of Italy, when he made the well-known statement, that the healthiest season was the spring, then the winter, then summer, and lastly the autumn. (a) The figures for Marseilles and Montpellier agree in placing the Roman spring at the top of the scale as the healthiest season, and the Roman autumn at the bottom as the most fatal to life.

(a) "Remarks on the Frequency and Fatality of Different Diseases, particularly on the Progressive Increase of Consumption, with Observations on the Influence of the Seasons on Mortality." By William Woolcombe, M.D. 1808.

(a) "Igitur saluberrimum ver est; proxime deinde ab hoc, hiems; periculosior aestas; autumnus longe periculosissimus." Lib II., cap. i.

Having now converted Short's eleventh table, which presents us with the deaths that took place among the population of London during the early part of the last century, from a table of reference to a table of discovery, by arranging the figures in accordance with the probable theory that temperature to a great extent governs mortality, and found that theory to be justified by the figures, Dr. Guy then proceeds to treat Short's more elaborate table, the fifteenth of his series, given in full by Heberden at page 47, in the same way; that is to say, by submitting it to the same process of analysis by re-arrangement, as he had already adopted in respect of Short's eleventh table. This table is described as a table "for fifteen years, viz., from 1st January, 1728, to 1st January, 1743, being monthly, and begins with January and ends with December." It comprises an aggregate of 405,951 deaths.

As this table was extracted by Heberden from Dr. Short's work, Dr. Guy first collated the one table with the other, and found that Heberden's table contained two misprints, one of slight importance, the other so considerable as to seriously affect the results; and as it happened, gave rise to the solitary exception to the rule which the remainder of the figures established.

Having made this necessary correction, Dr. Guy proceeded, as he did with the first table, to transform it from a table of reference into a table of discovery, commencing with the column of deaths for all ages. When the figures of this column were arranged in three groups of four months each—the four coldest, four hottest, and four temperate months—the total were found to fall into the order already made out:—

Four cold months, 146,917; four temperate months, 136,423; four hot months, 122,611.

So that again, and for a different series of years, the death-rate was found to vary inversely as the temperature. The figures of the two distinct series of fifteen years (the first fifteen ranging from 1728 to 1743; those of the second series from 1732 to 1747, yield the same results, and so far confirm each other.

It is also worthy of remark that though the two sets of figures, both for the months and groups of months, differ throughout, the differences between the extreme numbers for the cold and hot seasons approximate very closely. The difference between the extremes in the first being 24,163, and in the second 24,306.

Another fact worthy of notice is, that when the figures of the three sections of the year are reduced to centesimal proportions of the totals, the percentages expressed in round numbers are identical. They are as follows:—Four cold months, 37 per cent.; four temperate months, 33 per cent.; four hot months, 30 per cent.

(To be continued.)

## STIMULANTS IN WORKHOUSES—ALCOHOLIC LIQUORS AS MEDICINES FOR THE SICK.

By NORMAN KERR, M.D., F.L.S., London.

(Concluded from page 266.)

It cannot be denied that medical officers have sometimes laid themselves open to criticism by lavish and indefensible prescription of intoxicants. For instance, in a parish in Ireland in 1873, a district medical officer ordered creature comforts to an out-door pauper to the extent of £1 6s. per week. During the discussion of the case at a meeting of the board of guardians, the doctor recommended the addition, to the weekly grant of £1 6s. of from 14 to 20 glasses of brandy weekly. The *Medical Press and Circular* very properly condemns this indiscriminate prescription of liquor as a most unjustifiable use of authority, and, in the interest of Poor-law medical officers, a subject for regret and deprecation.

Whenever intoxicating drink is prescribed to any pauper, the medical officer should scrupulously take care to write the case off the books, or in some way discontinue the

allowance so soon as the end, for which the liquor has been ordered, has been gained. Otherwise the alcoholic remedy, once ordered, is apt to be continued indefinitely. By way of example, let me refer to the statement made by the medical officer of an extensive London workhouse in the spring of 1873. Attention was called to the enormous consumption of brandy, and the medical officer stated in explanation that the brandy, when ordered by him, was continued to each patient longer than he had intended, in consequence of an oversight on his part in not stating in the in-door medical book when the brandy so ordered was to cease.

Not infrequently the friends consume the brandy meant for the outdoor sick pauper. I was called once to a district parochial case in another district where the sick man, his wife, and his wife's sister were all under the influence of the liquor which was ordered medicinally for the sick man alone. Such cases are by no means uncommon. It would be a decided gain if, when brandy or any other alcoholic stimulant is ordered by the medical officer, the liquor were given in combination with some medicinal bitter, and were supplied to the patient in a mixture as a medicine, and not as an ordinary beverage. By many medical officers this course is followed. The only caution requisite here is to avoid adding to the attractiveness of the liquor, as has been done in one instance with which I am acquainted, the spirit being made more palatable than ever by the addition of cinnamon water.

When I believe a powerful and prompt stimulant to be urgently needed I hesitate to order wine or spirit—for therapeutic reasons—mainly because I have no confidence in the composition and strength of the liquid. Fermented wine, above all other drinks, is of very uncertain medicinal potency. Ordinary port and sherry, for example, range from 30 to about 60 per cent. of proof spirit. On such uncertain and variable compounds the enlightened medical practitioner can place little reliance. Then what is sold as wine is often a mere chemical concoction, in which the juice of the grape is either conspicuous by its absence, or is present only in a homoeopathic proportion. When pressed by clergymen and wealthy district visitors to order port wine in fever to the sick poor, I have told them that if they would place at my disposal some of their own genuine blue seal at 66s. a dozen, I would seriously think of it; but with the common port of commerce, such a prescription would be a mockery, and reliance on such a sham endanger the suffering sick one's life. For these reasons, from a scientific point of view, I prefer, where stimulants are indicated, to rely either on alcoholic tinctures, such as spirit ammon. arom., and spirit chloroform, or on spirit vini. rectificat. and tenuior, in combination with cloves, cardamoms, cinnamon, or other aromatics. By this method I know what I am prescribing, and I can prescribe the exact dose which seems to me called for. From a moral standpoint, too, I hesitate before ordering an intoxicating beverage. The bulk of our pauperism springs from drinking, and a large proportion of the diseases we are called upon to treat among the poor arises, directly or indirectly, from indulgence in drink. When we order them brandy or wine, or beer in illness, these wretched inebriates are delighted. Not only are their prejudices on behalf of their destroyer confirmed, but unhappily fuel is added to the fire already raging within them, and their craving for alcohol is strengthened and intensified.

Though probably if I had been in his place I would have prescribed even a smaller quantity of stimulant than he has, it seems to me that the true spirit in which to order stimulating drinks is well exemplified in a remarkably ingenuous and candid letter in the *Belfast News Letter* from the medical officer of the Coleraine Workhouse, Dr. Carson, himself a life abstainer. Dr. Carson says that the medical officer of a workhouse occupies a responsible post. He must do everything he can to save life, and, as far as consistent with this, save the taxes of the people. The plan he adopts as most satisfactory to his conscience is this. Never to prescribe ale, porter, wine or brandy, but to order malt whiskey as the best of stimulants. He never

gave stimulants as a mere cordial or luxury to nurses or any one else, old or young; but he gave whisky to all whose lives he believed it would assist in saving, and to no others. The number of patients on his sick list daily ran from 45 to 90, according to the season of the year, and he found, from a return made out for him by the clerk, that the quantity of whisky prescribed during two years ending September, 1879, was just 45 quarts altogether. Dr. Carson adds that he has been a teetotaler since boyhood, and prescribes stimulants on principle, not from taste.

If we carry out the experiment in Dr. Carson's spirit, we will ere long be justified in coming to some definite conclusion as to the true usefulness of alcohol and alcoholic drinks in the treatment of the sick poor. Mr. Dolan, of Halifax, justly says that, with the ample material at our command, furnished by the numerous union infirmaries in England, it must be possible to arrive at an approximate and truthful estimate of the real value of alcohol in the treatment of pauper patients.

May I venture to appeal to my colleagues in the Poor-law service throughout the kingdom to give the whole subject serious and impartial attention? That evils, many and grievous, arise from the presence of strong drink in our workhouses, no one will venture to deny. The entrusting of a night supply of intoxicating liquor to nurses and attendants, in the event of a sudden call for a prompt stimulant, especially among the aged and infirm, is a temptation too strong always to be resisted. There are stimulants which would answer the purpose as well, which would not present such temptations to abuse. A comprehensive and exhaustive description of non-alcoholic stimulants has been prepared for the South Dublin guardians by the Chairman of their Stimulant Committee, the experienced and judicious Dr. Evory Kennedy.

Nothing mars the good conduct and discipline of a workhouse as does the presence of intoxicants. At a recent meeting of the Shoreditch guardians the master reported the house to be so full that he was obliged to use the receiving wards to accommodate paupers when they returned to the house the worse for liquor. To see indoor paupers, in the garb of the house, intoxicated in the streets of London, is no uncommon sight. The shocking prevalence of drunkenness among the inmates on their return in the evening of their day for leave of absence, is well known. The records of our police-courts amply attest the existence of this deplorable state of things. In the Holborn Workhouse lately a woman represented to the doctor that she was very ill, and was allowed a certain quantity of brandy. It was afterwards discovered that immediately the allowance was given to her she began to sell it to the other patients in the ward. So impressed were the Lord's Committee with this aspect of the stimulants in workhouse question, that they inserted the following in their report:—"The supply of alcoholic drinks to the poor, whether given in workhouses or to out-door poor (except in cases in which it is medicinally indispensable), has a tendency to create a taste for stimulants in those who perhaps would not otherwise have acquired it, and it leads ignorant people to conclude that as wine and spirits are prescribed for them by the doctor, and supplied by the relieving officer, they must be a needful remedy in most cases of illness, and thus the habit of flying to the bottle for relief is created, and the groundwork is laid for habits of indulgence and intemperance, which would otherwise never have been acquired."

Such being the evils so apt to flow from the presence of intoxicating drink in workhouses and infirmaries, and as it is an acknowledged fact that the great majority of our pauperism springs from intemperance, would it not be a most excellent consummation if the ordinary profusion of these beverages were almost, if not altogether, dispensed with? There is, as we have seen, reasonable ground to believe that the health of the poor would not suffer, and that the mortality would not be increased. It is certain that their behaviour and their *morale* would be improved, that many painful scenes would be pre-

vented, and that discipline would much more easily and effectively be enforced. I ask not for the absolute exclusion of alcohol, but in the interests of the poor themselves, of the ratepayers, and of the community at large, I do earnestly entreat my colleagues to steadfastly set themselves to inquire whether they can conscientiously try the experiment of treating the many afflicted ones under their care with the smallest amount of alcohol compatible with safety.

## ON THE VARIOUS TREATMENTS OF ANEURISMS. (a)

By W. J. WHEELER, M.D.,

Master of Surgery of the Dublin University; Fellow and Member of Council, Royal College of Surgeons, Ireland; Surgeon and Lecturer on Clinical and Operative Surgery to the City of Dublin Hospital.

In this designedly brief communication I do not purpose entering into any lengthened account of the various treatments of aneurisms, which even to the present time there is some difference of opinion.

The treatment by pressure, to which I am more particularly alluding, does not appear to have made much way, though used by Hunter and advocated by Freer; indeed, Guthrie dismisses it in his work on "Diseases of the Arteries" in a manner that would seem to ridicule it. Truly, it was not till Irish surgeons perfected this treatment, and demonstrated its application to that extent which produced the consolidation of aneurisms, that this practice received the place in surgery to which it has proved entitled.

To Dublin surgeons the credit belongs of not only perfecting compression but pointing out the cases for which it is most applicable; for, undoubtedly, there are some cases totally unsuited to this line of treatment, and if applied to such, not only disappoints the surgeon but brings the practice into disrepute. Those who would adopt compression where much œdema was present, or where the sac was about to rupture, or where the aneurism was quickly increasing in size, would surely have cause for disappointment.

The more completely the current of blood is cut off from the sac, the more rapidly does the cure take place; and for this reason digital pressure, when practicable, ought always to be adopted.

I could relate cases of aneurism thus treated to cure aided by position, and a strict observance of regimen. But my object is not to bring forward what has been frequently discussed at this Society—the general treatment of aneurism—but rather to confine myself to the treatment by the elastic bandage, and to hope that, should discussion arise, it will be limited to this.

C., male, æt. 37, in August, 1877, was admitted into the City of Dublin Hospital, and came under my care, for a aneurism situated in the left popliteal space. Up to two months before his admission he states he enjoyed good health. While at work about that time he felt a lump at the back of his knee, which caused him pain, and pulsated or throbbled continually. The posterior tibial artery could not be felt, but both anterior and posterior could be distinctly felt in his other ankle. The surface veins were larger than on the right side. There was no œdema of his limb. The tumour was about the size of a small orange, and a distinct bruit could be heard in it. On pressure of the common femoral artery the sac seemed to be completely emptied. The limb measured one inch and a quarter larger round the patella than on the sound side. He occasionally had cramps in the calf of his leg when standing or walking.

The patient suffered from diarrhoea for three days after his admission; so no treatment was adopted till the fourth day.

On Tuesday evening, the 31st of August, Signosini's

(a) Read before the Surgical Society of Ireland.

clamp was applied for a few hours; and on Wednesday, September the 1st, digital pressure was applied to the femoral artery, from 10 o'clock a.m. till 2 o'clock p.m., when it had to be given up, owing to the students not returning (there being only a few attending, clinical instruction having ceased during the summer recess), to continue keeping up the pressure. Signosini's clamp was applied for the remainder of the day, till 7 o'clock p.m. The limb was also flexed. The amount of pressure exercised on the common femoral artery did not completely stop the current of blood through the aneurismal sac. The clamp was shifted several times to keep the soft parts from injury, which were also dusted with French chalk; but, notwithstanding the precautions taken, the patient would not bear it longer than the above-named hour (7 o'clock).

On Tuesday, the 2nd of September, the limb having been elevated, for some minutes I applied an elastic bandage from the toes up to the inferior margin of the aneurism, and commenced applying a second similar bandage from the superior margin of the aneurism up the thigh, and compressed the femoral artery with the elastic band. The limb lost temperature; the pulsation ceased in the aneurism, which measured one-eighth of an inch larger circumferentially.

After 65 minutes the patient complained of so much pain and uneasiness at and above the seat of constriction, that I was obliged to remove the elastic band, which I did gradually, the limb being elevated, and the precaution taken not to extend the leg, which had been flexed; and also to apply a compressor on the femoral artery close to the pelvis, and above where the elastic band had been. On removal of the band the pulsation returned, but not nearly so strongly as before. The tumour had become much more solid, and the external articular artery of the knee could be felt beating with as much force as is common to the radial artery. There was marked stasis in the cutaneous vessels (capillaries). The compressor was used for two hours, but did not stop the pulsation after that time. I elevated the limb, and re-applied the bandages as before described, making pressure a little higher up on the femoral artery than when it had been controlled by the elastic band previously. In 45 minutes I was obliged to remove it on account of the distress complained of by the patient, and did so after the manner described on the first removal. The pulsation had stopped. The tumour felt solid. The compressing tourniquet was, however, kept on the femoral artery for three hours, but scarcely any pressure exerted. Cotton wadding was applied round the leg, which was partially flexed. There was no constitutional disturbance; the patient only complained of some shooting pains in the calf of his leg.

Mr. Tufnell and others saw the tumour before and after the treatment. Up to the 11th of September the tumour was getting smaller, and perfectly solid. On that day the patient refused to remain longer in hospital, and said he was cured.

I am much indebted to Mr. Ashe, our present house surgeon, for his valuable assistance in this case.

The second case I wish to record is that of a young gentleman, *æt.* 23, who was sent up from the country to me in August last, to be treated for bursal tumour in his right popliteal space. The tumour, which was about the size of a walnut, was an aneurism; and on describing the nature of the ailment to his parents they became so alarmed that I suggested a consultation. Mr. Butcher saw the case with me.

The patient was of a nervous and excitable disposition, and I had difficulty in getting him to remain in bed for two days before applying treatment, during which time I gave him full doses of bromide of potassium.

On the morning of the third day I elevated the limb for two or three minutes, and then applied Esmarch's elastic bandage continuously from the foot to beyond the middle of the thigh, but very lightly over the aneurismal tumour. The elastic band contracted the common femoral

artery; the limb became blanched and cold; the pulsation ceased. He had borne the pressure only for twenty-five minutes, when he complained of pain, and said he could bear it no longer. However, a hypodermic injection of morphia relieved him, and with much persuasion he kept it on for fifty-two minutes. I was then obliged to remove it, which I did gradually, having first placed a tourniquet on the femoral artery above the band. No pulsation could be felt in the tumour. I even loosened the tourniquet for a moment, to make certain; but there was no return. Moderate instrumental pressure on the femoral was kept up for three hours. After the pulsation ceased the limb was bandaged with flannel.

The tumour gradually decreased in size. He left Dublin with a plaster of Paris bandage on his limb five weeks after I first saw him.

The two cases I have brought forward afford examples of treatment of what may be called the interrupted and uninterrupted by the elastic bandage. For my own part, I prefer the latter, and believe it will be found as efficacious as the interrupted, and that there will be less danger to the aneurismal sac than there is in the method of "locking" the blood in the sac.

In the first case I recorded there was some increase in the size of the aneurism, and tension of the sac. I compressed the femoral artery in both cases for some little time after the pulsation had stopped, in case the pressure of blood might injure the newly-formed coagulum.

I do not believe there is any danger of causing gangrene of the limb or rupture of the sac by this treatment, if ordinary precautions are used.

I consider the elastic bandage a great aid in the case of external aneurisms.

## Clinical Records.

### THE LONDON HOSPITAL.

*Case of Psoriasis, associated with Osteo-Arthritis, cured by Vegetable Diet.*

Under the care of MR. J. E. ADAMS, F.R.C.S.,  
Surgeon to, and Lecturer on Surgery at, the Hospital.

Reported by BLAGDON RICHARDS, B.A.

F. F. L—, *æt.* 19, in 1877 was admitted into the hospital for psoriasis. She had been attending for some time previous as an out-patient, without deriving any benefit. At that time she remained in the hospital five months, and was re-admitted on December 28th, 1880, for a return of the skin disease.

*Family History.*—Father and mother both dead; immediate cause of death unknown. Father used to suffer from rheumatism, and mother had ascites when she died. Three brothers and three sisters all living, and in good health.

*Previous History.*—Patient has always been weak and delicate from a child. When very young she had measles and rheumatic fever. After her recovery in 1877, she was apprenticed at a fancy depository at the seaside, and in January, 1880, she was admitted into the London Hospital, under the care of Dr. Stephen Mackenzie, for chlorosis. She remained under his care for five weeks, and went out considerably better. Her chief symptoms at the time were (1) irregular menstruation, (2) *anæmia*, (3) palpitation, (4) weakness (discs normal), (5) dyspepsia, (6) *anæmic* bruit at base of heart. On July 14th, 1880, she was re-admitted, under Dr. Mackenzie, for osteo-arthritis, mitral systolic murmur, and psoriasis, and remained in the hospital till October 29th. The high temperature was controlled by salicylate of soda and quinine. After treatment, tonics and cod-liver oil. She left the hospital much improved, but still suffering from the psoriasis.

*The Skin Disease—First Attack.*—The disease first commenced in 1876, in her left leg; and the remedies applied and drugs administered in the out-patient department were ineffectual to stay its progress. After her admission she

was treated first with liq. soda arsenicalis,  $\pi$  x., ter die; and locally was applied spongo-piline, soaked in liq. carbo. detergens. Afterwards she used the following ointment:—

Hyd. oxid., flav., gr. x.;

Oleum Amygdalæ, quant. suff. Ft. unguentum.

She used at the same time hot water to promote perspiration. No improvement took place until her diet was altered; and this was restricted to vegetables alone, when an immediate amelioration of her symptoms supervened, and she rapidly got better.

**Second Attack.**—Commenced about two years ago (one year after the first), by a small patch on the lower part of her back. The patch was at first red, and small in size. It gradually became white, and increased in size. She also had a very small place on the top of her head. These places gradually spread, and she then noticed patches on the dorsal aspect of her feet, and afterwards in the palms of her hands. The eruption then became general, but was worse on the back than on other parts of the body. She had an attack of rheumatism about this time, which is mentioned above; and she noticed that as the rheumatism became worse, the eruption also increased in intensity, but did not improve as her rheumatism got well.

**Present Condition.**—December 28th.—Patient presents a scaly eruption all over her body and extremities, with the exception of her face, which is quite free. The eruption consists of red scaly patches, circular in character, and affecting more especially, and being more marked on, the extensor than on the flexor aspects of the extremities. There are in several situations on her body "heaped up" patches of epidermis, which resemble rupia in character.

**Treatment.**—

Locally— Liq. carbo detergens; and  
Ung. petrolei.

Internally—Mistura quina.

**Diet.**—Strictly vegetable.

January 6th.—Patient is improving. The scales are rapidly falling off, leaving a reddish condition of the surface of the skin underneath.

14th.—Patient is getting much better under the vegetable diet, but can now only use the ointment, on account of rheumatism.

20th.—Patient is a great deal better, and the skin disease is almost cured. The epidermis is still hard, and somewhat scaly in places, but where the scales drop off there is no redness whatever. Patient to get up this evening. She still continues to keep to vegetable diet, and use the ointment. She complains of severe pains at the back of the head.

25th.—Patient to have warm bath.

28th.—Two eggs each day. Disease nearly altogether disappeared.

February 8th.—Patient still suffers from pains in the head, and rheumatic pains in the shoulders. She sleeps well, and is in good general health, eating with a good appetite, but some distaste for the vegetable diet. The psoriasis has altogether disappeared.

**Remarks.**—Perhaps it is to be regretted that in the treatment of the second attack any local application was used, as it may be said that the lotion cured the disease rather than the diet. It must, however, be borne in mind that in the previous attack no improvement took place under the same local treatment, until the alteration in diet was made. Vegetable diet has been tried many times in cases of psoriasis, and has very frequently proved to be absolutely useless; but Mr. Adams thinks that in cases where ordinary internal and local treatment fail to improve the condition, that a vegetable diet should certainly be tried. Probably, or rather possibly, these general "dermatites" depend upon some chemical changes in the blood or tissues, and that we may not be able to determine the exact process by which they are brought about; but so long as any doubt exists, it is worth while to use any simple means, such as this one of restriction of diet, if other means fail. The convalescence from the previous attack was so marked from the date of the commencement of the diet that Mr. Adams did not feel justified in experimenting with the lotion alone; and in the interests of the patient prescribed the vegetable diet in addition, though feeling that for scientific purposes it would have been better to prove a second time the failure of one before employing the other.

## Transactions of Societies.

### SURGICAL SOCIETY OF IRELAND.

A MEETING of the Surgical Society of Ireland was held on Friday evening, March 4th, 1861, in the Albert Hall, Royal College of Surgeons.

Mr. HENRY GRAY CROLY, senior member of the Council of the Society present, in the chair.

Mr. RICHARDSON, Hon. Sec., read the minutes of the previous meeting, which were confirmed.

#### EXCISION OF THE SHOULDER-JOINT.

Mr. H. G. CROLY (Mr. E. S. O'Grady having taken the chair *pro tem.*) exhibited a specimen of disease of the right humerus of a young man, *æt.* 17, whose history had been given by Mr. Lambkin, the resident pupil of the City of Dublin Hospital. The patient, who was admitted on the 22nd February, was a labourer. He stated that about seven years before, he fell on his right shoulder, but was not much hurt at the time, having been able to use his arm a few days afterwards. Six years after the fall, an abscess formed at the back of the joint and burst; the joint then gradually got stiff until he could not move it at all. For the abscess he was treated by a drainage tube before he came into hospital, and he got some relief from the drainage, in the vicinity of the joint. On his admission the chief symptom was intense pain on pressing over the head of the humerus. There was a sinus over the anterior part of the humerus about four inches below the joint, and another near the angle of the scapula. In consultation the case was seen by Mr. Tufnell who agreed with Mr. Croly that it was one in which excision of the shoulder-joint ought to be performed. In accordance with experience of excision of the shoulder-joint the long tendon of the biceps was destroyed. The capsular ligament of the joint was greatly thickened and there was not an atom of cartilage found on the head of the bone. The periosteum, at the point of a second section he was obliged to make, was properly related to the bone. It was only necessary to gouge the glenoid cavity superficially, the bone under the eroded cartilage being perfectly sound. It was singular the disease was not more extensive.

#### ANEURISM OF ARCH OF AORTA.

Mr. F. J. B. QUINLAN showed a recent specimen of aneurism of the arch of the aorta. The patient, a strong, athletic man, *æt.* 61, had never complained of any symptom, except an increasing coldness of the right upper extremity up to the day before his death, which was caused by anæmia, the result of obstruction of the circulation. This absence of pain was remarkable as the aneurism, which was of very large size, had eroded the sternum in front and the rings of the trachea behind. It also pressed upon the recurrent laryngeal nerve, causing stridulous breathing. The interior of the aneurism was filled by a mass of fibrine of old standing, laminated at the walls of the vessel, and becoming gradually softer towards the centre which was filled by recent coagulum. An embolic process of this coagulum occluded the right subclavian artery. Mr. Quinlan pointed out all these appearances, and added that, on the day of death the pupil of the right eye was dilated.

HAIR-PIN REMOVED FROM THE VAGINA AFTER IT HAD LAIN THERE FOR UPWARDS OF SIXTEEN YEARS AND HAD CAUSED A VESICO-VAGINAL FISTULA.

Dr. ATTHILL spoke as follows, regarding the specimen:—A. B., *æt.* 30, unmarried, came under his care, suffering from symptoms of an undecided character. Of these the most prominent were diarrhoea, spinal irritation, and inability to walk. Menstruation recurred normally, but was scanty; there was a good deal of leucorrhœa. She had been under treatment for years, it being mainly directed to the spine, but little improvement taking place, her present medical attendant thought it probable that her symptoms were due to some uterine affection. She, however, absolutely refused to permit him to make a vaginal examination, and it was with great difficulty that Dr. Atthill succeeded in doing so. The orifice of the vagina was very small, but the finger had not penetrated an inch till it came in contact with a foreign body which, though partially embedded in the anterior wall, was at once recognised to be a hair-pin; and the patient admitted that she was aware of one being there. On being questioned

she stated that while quite a little girl, not more than twelve or thirteen years old, she had pushed a hair-pin up into the vagina, and not being able to get it back had concealed the fact; that at first it caused some discomfort, but that though conscious of its presence, she had for years given it little thought. She was, however, aware that a portion of it had come away. On bringing the patient under the influence of chloroform and exposing the parts by means of a duck-bill speculum, the blunt end of the hair-pin was seen in close contact with, and rather behind, the cervix uteri. One leg which evidently had been free in the vagina had broken off at about its middle; the other had pierced the vesico-vaginal septum, and lay in the bladder. Seizing the portion of hair-pin, which was in sight, with a pair of blunt forceps it was pushed upwards and backwards into the posterior cul-de-sac of the vagina with the view of drawing out of the bladder the part which was in it, but it was so thin that it broke. However, Dr. Atthill succeeded without much difficulty in extracting both fragments through the vagina. The length of the hair-pin was, before it broke, exactly three inches; of this the portion which lay in the bladder measured nearly two. After extracting the fragments the bladder was examined, and on passing the sound through the urethra, a fistula was found to exist between the vagina and bladder; this was of considerable size; it was situated in the upper third of the vagina, and permitted the sound to pass through with ease; the edges were quite round, and strange to say, though nearly a quarter of an inch in length, the patient never had incontinence of urine, nor, though a portion of the hair-pin must have for years lain in the bladder, was it incrustated with urinary deposits; nor had she suffered from the symptoms usually existing with the presence of a foreign body in the bladder. That the urine did not escape from the bladder was probably due to the fact that the fistula was valvular; the other two facts are not so easily explained. The patient was very comfortable after the removal of the hair-pin; and as there was no escape of urine it was decided to postpone any operation for the closure of the fistula for the present, it being considered likely that Nature would effect this, the foreign body being removed which had kept it open. The patient's condition rapidly improved, and she soon became almost perfectly convalescent.

#### MEDULLARY CANCER OF PENIS.

Dr. M. KILGARIFF exhibited a specimen of cancer involving the penis, which he removed on the 24th ult. from a patient, æt. 55, in the Mater Misericordiarum Hospital. About four months previous to his admission, he noticed a small swelling towards the anterior part of the organ. However, it caused him no inconvenience, nor did it grow with any appreciable rapidity for some time; in fact, remaining in a stationary condition until about five weeks ago, when its growth became very energetic indeed. About three weeks after the growth becoming so very active, a protrusion appeared through the preputial orifice. This pressed the urethra, causing considerable difficulty in micturition. Still it caused him no pain; but the symptoms became so alarming, he came to town, and placed himself under Dr. Kilgariff's care. Dr. Kilgariff amputated the organ at the pubis. On making a longitudinal section of it, it would appear to consist apparently of two dissimilar parts; an anterior portion, which was small, the greater mass being situated behind. In appearance, colour, and consistency, the anterior portion strongly resembled a broiled kidney; while the mass behind, which was rather egg-shaped, on its removal was about the size of a turkey egg, and appeared uncommonly like the section of a healthy testicle. The spermatic cords and the inguinal glands were free from any implication. From the history of the case, it struck him as questionable that the original swelling, which the patient stated commenced four months before, and was in shape like a grain of oats, ever constituted a portion of the tumour. On making the longitudinal section, the knife did not divide the skin inferiorly; it stopped short at the urethra, and the mass implicated every tissue of the organ, except the skin. The corpus cavernosum on the left side, was quite unrecognisable. Portion of that body was indisputably on the right side. The growth struck deeply, and invaded portion of the substance of the corpus spongiosum. Degeneration had commenced, and in some places was more advanced than in others. The history of the case pointed to the disease being malignant. His colleague, Mr. Coppinger, had made sections of it, and pronounced it to be a medullary carcinoma, which was rarely found in this organ; so that the specimen was one of interest.

#### CARIES OF MASTOID PORTION OF TEMPORAL BONE.

Mr. WM. WHEELER exhibited portion of the temporal bone which he had removed on the previous Thursday by the trephine, from a patient in the City of Dublin Hospital. The specimen was one of great interest, on account of the comparative infrequency of the operation for the disease, as well as of the appearances of the specimen itself. The patient, æt. 56, had had a discharge for a long period from his right ear, with pain and occasional throbbing. More than two months ago he had typhus fever. On his recovery from the fever, a swelling came in the soft tissues behind his ear. The pain increased. On cutting into the soft tissues, a quantity of matter flowed, about an ounce. The temporal bone was denuded and roughened. Appreciating the precarious condition of the patient, he determined to trephine him, and thus give free exit to pus. Placing the crown of the instrument a little above the level of the external ear, he reached the large spaces lying close above and behind the tympanum. The pus did not flow directly the bone was removed, but since the operation there had been a free discharge, and the running from the external ear had entirely ceased. On close examination of the bone, it could be observed that its inferior surface opened into the cells, and that on its internal and superior surface the bone was worm-eaten and carious. Since the operation the patient had done well; his pulse being 80, and his temperature 99°. Pus continued to flow through the opening. He considered the specimen and the operation worthy of the Society's attention.

Mr. WM. WHEELER read a paper on

#### THE TREATMENT OF EXTERNAL ANEURISM WITH ESMARCH'S BANDAGE,

which will be found on page 289.

Mr. TURNELL said he had seen the first case mentioned by Mr. Wheeler in hospital; and he had observed the application of Esmarch's bandage lightly over the tumour, but firmly above and below it, so as not to run any risk of rupturing the sac while confining the blood. That mode of treatment answered remarkably well, but was not to be adopted where the patient had to be left, as in dispensary practice, for many hours. In applying Esmarch's bandage, it should be done in hospital, or where the patient was under surveillance. The same remark might apply to all pressure except the digital. In the digital the pressure was sustained; but where the pressure was instrumental, the remark was certainly applicable.

Mr. ED. BENNETT asked Mr. Wheeler to give some further details with reference to the second case; because he had heard nothing as to the nature of the aneurism, the symptoms associated with it, the age of the patient, or the history of the case. There was another point which, perhaps, was an oversight. Mr. Wheeler had mentioned that he applied the compressing tourniquet over the common femoral; but that he assumed to be a mistake for the superficial femoral.

Mr. A. H. CORLEY did not know whether or not Mr. Wheeler had clearly indicated the particular kind of cases suitable for that mode of treatment. On theoretical grounds, he would be rather doubtful of treating aneurism in that way. Anyone that saw the extraordinary vascular excitement in the limb when the bandage was taken off, the erysipelatous blush that suffused the entire limb, would conclude that the danger of an unfortunate event would be more likely under that form of treatment than any other. Where it occurred in a very young subject it might be assumed there was no arterial disease present. But in the usual case of an elderly man, as far as his judgment went, he would prefer trusting to the method in which there would not be the same risk of subsequent vascular excitement.

Mr. E. S. O'GRADY referred to the case of a man going about the Dublin hospitals for a good many years who had arterio-venous aneurism of the leg fifteen or sixteen years. He did not know whether the treatment adopted could be compared to that of Esmarch's bandage, but he used an elastic bandage from the toes to the groin. Among others he was under the care of Mr. Wheeler. Though the bandage was used with considerable firmness, it was not applied so firmly as an ordinary Esmarch's bandage. However, the sequel was that the lower tumour in the thigh advanced from bad to worse; in fact, to the verge of bursting. The femoral artery, which was larger than his thumb, he divided and tied each end. The man recovered for a time. He returned again with the aneurism higher up, close to the groin. It burst. The man lost a great deal of blood, and the vessel was dilated

almost to the size of the funnel of the lamp. He died of shock. It was a matter for consideration whether the enormous dilatation of the vessel, and all the vessels about the locality would, in any way, bear on what Mr. Corley had spoken of as the possible consequence of the use of Esmarch's bandage. In three cases he had seen the consummation of aneurism preceded by diarrhoea, so much so that he looked on it as *post hoc propter hoc*.

Dr. NIXON having made the post-mortem examination in the case alluded to by Mr. O'Grady, desired to bear him out as to the size of the external iliac artery, so that he took it to be portion of the small intestine. It was considerably larger than the abdominal aorta. It was also worthy of notice that the corresponding iliac vein was considerably larger than the vena cava. All the vessels of the thigh were enormously enlarged. The specimen was in the museum.

Mr. O'GRADY remarked that he had omitted to mention what Dr. Nixon stated as to the size of the iliac artery. It was about the size of the small intestine—an inch and a-half in diameter. Indeed, it looked like a coil of intestine.

The CHAIRMAN.—Was not there a varicose condition of the veins of the leg all through?

Mr. O'GRADY.—I had succeeded in curing that long before. I had injected it.

Mr. B. WILLS RICHARDSON.—Did you say that you tied the common iliac in that case?

Mr. O'GRADY.—Yes.

Mr. RICHARDSON.—What was its size?

Mr. O'GRADY.—Normal.

Dr. NIXON.—There were aneurismal dilatations, either two or three, below the site of the original aneurism. There was also an aneurism at the point where Mr. O'Grady placed the ligature on the common femoral vessel.

The CHAIRMAN.—I remember seeing that man myself on more than one occasion. It struck me as being a remarkable case of arterio-venous aneurism of a very unusual character, the limb being almost elephantine, with large veins and arteries—anything but a nice-looking case.

Mr. WHEELER replied with regard to the history of the second case that had been asked for—indeed, he might say that both cases would have been recorded more fully had he anticipated that his communication would positively be read that evening, but he expected that the gentleman whose name preceded his on the list would not have disappointed. He observed that the only reason assigned for the popliteal aneurism in the young gentleman was the exertion of jumping over the wickets while playing at cricket, to prevent himself from being run out. It was the superficial femoral artery he compressed, and if he had said common femoral it was a mistake. As to the sudden flow and return of blood when the elastic bandage was removed, he mentioned specially that he had compressed the main artery of the limb with a tourniquet to prevent it. He believed it was better to apply the bandage continuously, and not to lock the blood in the sac, as he did in the first case. He could not say whether or not the bandage would be equally applicable in the case of elderly persons, and where much disease existed, having had only two cases of aneurism treated in the method described, and as far as he knew, there was not further experience of it in Dublin. However, had he to deal with an old person he would, he thought, exert some form of pressure before the bandage, in order that the collateral circulation might become somewhat established prior to its application. The case of arterio-venous aneurism referred to by Mr. O'Grady did not appear to him to bear on his communication.

The Society then adjourned.

#### ASSOCIATION OF SURGEONS PRACTISING DENTAL SURGERY.

WEDNESDAY, MARCH 16, 1881.

THOMAS EDGELOW, L.R.C.P., President in the Chair.

#### IMPERFECTIONS IN THE DENTAL ACT.

Mr. W. A. R. CATTIN drew attention to a courteous letter he had received from the Secretary of the Royal College of Surgeons of England, asking him to correct one or two slight errors into which he appeared to have fallen in his recent address "On the Imperfections of the Dentists' Act," when alluding to the license in midwifery. It would

appear that out of the three unqualified persons who were examined for the license in midwifery, only one (*not three*) received it, and two were rejected. From the regulations respecting the license, a copy of which accompanied Mr. Trimmer's letter, he ascertained the fact that candidates who were members or licentiates of other Colleges, or who had passed through a curriculum of education prescribed by Rule vi. were, up to 1875, entitled to be examined for the license in midwifery, so that he was wrong in saying only members of the College could receive it.

#### CASES IN PRACTICE.

Mr. EDWARD BARTLETT read a short paper on the four following cases:—

Case 1 was that of a girl, *æt.* 20, with a supernumerary tooth posterior and between the central incisors, and which appeared at the same time as the centrals.

Case 2 was that of absence of the second bicuspid, which was accounted for by the posterior deciduous molar being forced nearly into the antrum by the closure of the first bicuspid and molar over it. This (the crown of the molar) Mr. Bartlett removed, which felt, on exploration, like dead bone being covered with tartar.

Case 3.—Two very large supernumerary teeth, and a lateral, which he had removed from the mouth of a man, *æt.* 33, who had a third central incisor indistinguishable from the normal ones.

Case 4 occurred in a young lady, *æt.* 19, in which all the permanent teeth were absent, with the exception of the two centrals, two canines, and two molars; some of the temporary teeth remaining in their position.

The PRESIDENT stated that he had described an almost identical case to that of No. 2 to the Society only a few months since.

Mr. HAMILTON CARTWRIGHT (the Treasurer) then made some remarks on

#### THE TREATMENT OF RIGG'S DISEASE,

Consisting of the destruction of the periosteum of the teeth, absorption of the alveoli, and ultimate loosening and loss of the teeth. He said that it generally commenced in an unhealthy condition of the gums, and that he believed the deposit of tartar to be secondary to the disease: the deposits of the saliva pocketing between the separated gum and the teeth. Of course the first and most important matter was to remove the tartar effectually, but he still held that much might be done by a very, so to speak, "heroic" treatment with the knife, and echarotics used alternately. The Treasurer then gave his mode of treatment in detail.

Mr. HAMILTON CARTWRIGHT then showed

#### A REMARKABLE CASE OF THE JAW OF A DWARF,

about three feet high, and compared the denture with that of the American Midgets. The dwarf was the child of wealthy parents, and grew normally for some months, when the development of his body became completely arrested, whilst that of the head and brain continued to get to a great extent. The boy is about 16 years of age, and highly intelligent, having recently gained a prize for French at school, and having a great taste for study generally. He walks, however, with difficulty, his head being so much larger than his body, but otherwise is of a bright and lively disposition. His teeth, unlike most dwarfs, are not deficient, as in the case of "the midgets," but consist of a perfectly formed first set. In the upper jaw only the first molars had been shed to give place to the bicuspids, which are nearly erupted, whilst the six year old molars are just appearing. In the upper jaw there is a perfect set of milk teeth, without any sign of caries. In conclusion, he wished to draw the attention of the Society to the analogy existing between the teeth and dermic structures in their development, and that, as a rule, both the hair and teeth were deficient in dwarfs; but that, in this case, the hair was as perfect as the teeth; the only peculiarity in the latter being the persistence of the first denture up to the age of sixteen years.

On Monday next an amateur performance of "Out of Sight," and "Les Beaux Arts," will be given at Cromwell House in aid of the new out-patient wing of the Victoria Hospital for Children, Chelsea.

## Department of Lunacy.

### THE NORTHUMBERLAND COUNTY ASYLUM.

IN explaining the fact that the rate of recoveries calculated on the number of admissions in the Northumberland County Asylum for last year were unusually low, being only 26·8 per cent., Dr. McDowall, the Medical Superintendent, justly observes that annual fluctuations in this rate are often dependent on circumstances over which the officers of the asylum have no control. A large number of admissions towards the close of the year, or the practice of sifting paupers through work-houses, will unduly depress that rate, while a preponderance of admissions in the earlier months of the year, and a prompt resort to asylum treatment in all cases of insanity on the part of the poor-law officials, will proportionately raise it. But Dr. MacDowall goes too far when he says "in any asylum the rate of recoveries and deaths depends far more upon such circumstances and upon the character of the cases admitted than upon the treatment adopted. . . . These variations from year to year mean nothing, and are of no importance." If this be so, and if the system of treatment pursued in any asylum has no influence in promoting recovery or postponing death, then it may well be asked why medical officers with large salaries should be attached to such institutions? If, again, the rate of recoveries and deaths in a lunatic hospital has no insignificance whatever, but is the mere sport of incalculable circumstances, the question will arise by what standard are these establishments to be judged, and how are they to be compared with each other. The truth would seem to be that the death-rate and recovery-rate in each asylum are full of meaning to those who can read them aright, the circumstances which produce their annual variations being capable of statement and calculation. No doubt a juster estimate may be formed of the state and management of an asylum by a survey of the results of treatment over a series of years, but very fair inferences may be deduced from the summary of even one year's work, when that is accompanied by necessary explanations. It would be unfortunate should asylum medical officers come to think that the rate of recovery and deaths in the establishments under their care is beyond the province of criticism.

### THE EAST RIDING LUNATIC ASYLUM.

THE annual report of the East-Riding Lunatic Asylum, at Beverley, has just been published. On the 1st of January last, the establishment contained 260 patients. During 1880 the death-rate was 9·69 per cent. calculated on the average number of patients resident, and the rate of recovery was 52 per cent. calculated on the admissions. These figures justify the verdict of the Commissioners in Lunacy at their annual inspection that the present management of the asylum is satisfactory. Dr. Whitcombe, the Medical Superintendent, who is responsible for that management, notes many alterations and improvements that have been effected during the last twelve months, all tending to augment the comfort and promote the recovery of the inmates of the hospital. He refers in his record of surgical experiences to an operation for strangulated femoral hernia performed on a male patient, which evidently contributed more towards the recovery of his mental faculties, than the various drugs previously administered to him. Improvement commenced immediately after the operation, and continued uninterruptedly until the patient was discharged. The want of a detached hospital for the treatment of contagious diseases is, Dr. Whitmore says, keenly felt. Dr. Henry Godfrey James, the assistant medical officer of the

Asylum died in April last, and a graceful tribute is paid to his ability, integrity, and devotion to his duties up till within a few days of his death.

### THE KILLARNEY DISTRICT LUNATIC ASYLUM.

DR. OSCAR T. WOODS, of the Killarney District Asylum, has done an excellent work in calling attention pointedly in his annual reports to the mode of admission of a large proportion of patients, as dangerous and criminal lunatics, into Irish asylums. This mode of admission was condemned by fourteen medical superintendents of Irish asylums in their answers to the Poor-law Union and Lunacy Inquiry Commission, and yet it seems to prevail as widely as ever. Its evils are not far to seek. To brand as criminal, and to pass through the hands of the police an unfortunate being whose only offence is that he is suffering from a disease of the nervous system, is to inflict an injury on him, on his family, and on the public; on him by imperilling his prospects of recovery, on his friends by reflecting some discredit upon them, and hurting feelings already sorely wounded, and on the public by breaking down those strong barriers which ought always to separate visitations of Providence from vicious acts. Dr. Woods adverts to another evil consequence of the abuse of the criminal warrant, and that is, that it deprives the medical staff of the asylum to which the patient is consigned of reliable information concerning him which might guide at once to suitable treatment. The police who accompany him have not that acquaintance with his antecedents which his friends and neighbouring Poor-law officials would naturally possess. It is to be hoped that steps will be taken to remedy the evils which Dr. Woods has so clearly set forth.

## The Mineral Waters of Europe.

### THE "MEDICAL PRESS" ANALYTICAL REPORTS ON THE PRINCIPAL BOTTLED WATERS.

By CHARLES C. R. TICHBORNE, LL.D., F.O.S., F.I.C.,  
President of the Pharmaceutical Society of Ireland, &c.

WITH

### NOTES ON THEIR THERAPEUTICAL USES.

By PROSSER JAMES, M.D., M.R.C.P. Lond.,

Lecturer on Materia Medica and Therapeutics at the London Hospital, Physician to the Hospital for Diseases of the Throat, &c.

(Continued from page 278.)

### VICHY WATERS (continued).

IN our last article we concluded the analyses of the Vichy waters, and we now wish to make a few remarks upon the bottling of these important waters. We do not wish to insinuate that other waters are not bottled equally well, but the Vichy springs being under government supervision, we have an insight into the matter which is not afforded by the general run of information given in other cases. The question of bottling is one of great importance in connection with the importation of mineral waters, and when we observe that very few mineral waters will stand any considerable time without giving a sediment, we see the desirability of dwelling a little time upon this subject.

As regards the Vichy waters, the corking is done by machinery, and good corks are specially selected. There

is an excellent system pursued in connection with them which should be carried out with all the others. Each bottle is secured with a tin capsule bearing the date of the year when it was bottled. Now, having regard to the change that might take place in mineral waters after keeping for some years, we cannot commend this practice too highly; there is no reason to suppose otherwise than that those waters which contain organic matter would, however well corked, become putrid after a lapse of time, such a change being quite irrespective of the deposition of many of their most active ingredients.

To illustrate the important commercial phase which the importation of mineral waters has assumed — Of Vichy waters alone, in 1866, 2,045,140 bottles were sent out, as against 350,000 bottles in 1853. M. Bouquet states that the average loss of carbonic anhydride in the bottled waters is about 10 per cent., but from our own observation this loss is very erratic. The last portions, however, of carbonic anhydride, are retained with great tenacity, and as, in most waters, the quantity required to keep the carbonates in solution is very small, the question is really not of so much importance. The iron is generally deposited by virtue of oxidisation, not by escape of carbonic anhydride. Still, all waters should be stored in cool cellars, with as much care as would be expended upon good wine; and the practice of placing the waters in shop windows, under a broiling sun, or on counters, is most objectionable.

COURT ST. ETIENNE.

*Arsenical Waters.*

Not a very great distance from the historic ground of Waterloo, some arsenical waters were discovered in 1878, at Court St. Etienne. The Court St. Etienne waters cannot be considered as purgative, but it is stated that it is one of the strongest and most permanent of the arsenical waters.

It has been analysed by Prof. De Wilde, of the University of Bruxelles, whose analysis runs as follows:—

Silica ... ..	0.0086
Ferric oxide ... ..	0.0090
Lime ... ..	0.0728
Magnesia... ..	0.0061
Potash and soda... ..	0.0193
Lithia ... ..	trace
Sulphuric acid ... ..	0.0776
Carbonic acid ... ..	0.0110
Chlorine ... ..	0.0176
Nitric acid ... ..	0.0346
Arsenic acid ... ..	0.0097
Organic matter and loss ... ..	0.0259
	— grm.
Total ... ..	0.2921
Less oxygen corresponding to ... ..	0.0039
	—
Chlorine, total per litre ... ..	0.2882 grm.

We do not find this water exactly the same, and would prefer to try and associate the acids and bases together. The specimen gave on analysis—

Chloride of sodium ... ..	1.80
Chloride of calcium ... ..	0.34
Nitrate of calcium ... ..	3.03
Sulphate of calcium ... ..	6.26
Sulphate of potassium ... ..	0.39
Iron (ferric oxide) ... ..	0.35
Silica ... ..	0.60
Carbonate of calcium ... ..	2.07
Carbonate of magnesium ... ..	1.03
Organic matter and loss ... ..	0.80
Lithia ... ..	trace
Arsenic (As <sub>2</sub> O <sub>5</sub> ) 0.5 = Arseniate of sodium ... ..	0.83

Total solids ... 17.50

Free carbonic acid and gases not determined.

*Skeleton Analysis of Half-a-pint (10 fluid ounces.)*

Total Solids.	Antacids.	Arseniate of Sodium.	Salines.
1 1-10th gr.	2-10ths gr.	.05	1-3rd gr.

The Court St. Etienne spring is evidently a very valuable water of a new character. It might, we should say, be indulged in rather freely, because the total solids are under 18 grains per gallon; but at the same time, it must be borne in mind that over 4½ per cent. of those solids consist of arseniate of soda. That the arsenic exists in water as the higher oxide of arsenic there can be little doubt, and in this respect it differs materially from such waters as Vichy, in which the arsenic is present as As<sub>2</sub>O<sub>3</sub>.

The water is perfectly neutral to phenol-phthalin owing to the fact of its antacids being only carbonates of alkaline earths. It contains no alkaline carbonates. It is also perfectly neutral to tropeoline, and seems to possess great permanent properties. It seems to be quite free from nitrogenous organic matter.

SMALL-POX is still very prevalent in London, Paris, Vienna, and Philadelphia; typhoid in St. Petersburg and Paris; scarlet fever in New York, and diphtheria in Berlin, New York and Brooklyn.

ACCORDING to custom, the election of President of the Royal College of Physicians of London will take place on the Monday before Easter. We understand that the honour is likely to be offered to Sir William Jenner, which, if accepted will necessitate the election of another Censor to the College.

OF diseases of the zymotic class in the large towns last week, scarlet fever showed the largest proportional fatality in Bradford and Sunderland; and whooping-cough in Glasgow, Newcastle-upon-Tyne, Leeds, Sheffield, and Portsmouth. Of the 29 deaths from diphtheria 9 occurred in Glasgow, 7 in London, 3 each in Edinburgh and Portsmouth, and 2 in Bristol. The death-rate from fever, principally enteric, was highest in Dublin, Portsmouth, and Oldham. Small-pox caused 52 deaths in London, and its suburban districts, one in Birmingham, one in Newcastle-upon-Tyne, and none in any of the other large towns.

## PRIVATE SCHOOLS.

THE important connection that exists between the surroundings of children and their physical development, is one that scarcely receives the attention it deserves from those directly concerned with the education of the young. School hygiene may be said to be a subject of all but present growth; its recognition as a factor in the determination of beneficial results has been of tardy acceptance, and even now it possesses for the majority of people only a vague significance. And yet but a little attention to all that it involves suffices to convince how essential it is for physical well-being to accompany satisfactory mental evolution. The two may be considered to advance *pari passu*; unhealthy physique and stunted intellect are inseparably connected, as surely as improper punitive proceedings entail immediate or future diseased conditions in the persons of the unfortunate victims of over-zealous authority. And until there is universal appreciation of the fact that sanitary arrangements in schools are as potent to produce healthy scholars, as well-devised methodical teaching, and a general attempt is made to carry out the rules of hygiene in every teaching establishment, we may not anticipate that the schools of this country will rise much above the position they occupy—a position the reverse of good, the antithesis of perfection.

In some measure, the buildings erected under the supervision of the School-Board officers are infinitely superior to the older primary schools, and in many of them the arrangements are such as to permit of well-devised schemes being carried out to secure an ordinary amount of ventilation and warmth. Such school buildings, however, are a minority only of those in which numbers of pupils are each day crowded together. In every town and village of the kingdom, there are to be found ordinary dwelling-houses distinguished by plates bearing the inscription "Establishment for Young Ladies," "Boys' Seminary," "Training Academy," and the like; and in these, during ordinary school hours, will be found classes of children, varying from eight or ten to twenty or thirty, cooped up in one or two rooms calculated to contain at most three or four people for any considerable length of time. The houses selected by the needy individuals who "open a school" as a last resource against starvation, are not likely to be particularly adapted to the purposes held in view by their tenants; the question of rent is a more important one to them than that of accommodation; and herein they and their charges are associated five hours or more daily, under conditions the most injurious to early physical growth. The continued respiration of imperfectly purified air, and the close confinement in a limited space unequal to the requirements of half the persons in it, cannot fail to react most injuriously on the children submitted to its evil effects; and that it does so is within the experience of every parent who has unwisely selected a preparatory school as the scene of his child's first educational efforts. Headaches, lassitude, dullness, general ill-health—these are again and again complained of without any assignable causes being apparent for their existence. A little inquiry, however, will in every case of this kind reveal the fact that the patient is in the habit of attending a local school, where, if examination of it is made, will be found ample evidence of the causes which are to blame for the child's indisposition. And even in the more pretentious schools, which aim at dignity of collegiate titles, but little better arrangements obtain. In them it is a common occurrence to pack from forty to fifty boys in a room twenty feet long by a dozen or fifteen wide, where they remain for periods of from two to three hours; and, in cold weather especially, with only so much interchange between the internal and external atmospheres as can take place through cracks for the admission of the draughts that go a long way to account for the prevalence of colds among juveniles in winter. In some better-conducted schools we have known it to be a constant rule to permit a class to occupy any one room for only an hour, or at most an hour and a-half. It is then taken into a second room, in which open windows have ensured the purification of the atmosphere within; and meanwhile the chamber vacated is thoroughly ventilated before re-occupation. This plan, incomparably superior as it is to that which permits the repeated breathing of vitiated air, is, nevertheless, open to serious objection. Unless thoroughly well warmed, the ventilated room cannot fail, in severe weather, to strike a chill to every sensitive child entering it from a warmer situation, and the danger of this can hardly be over-estimated. The growing child and youth are, until they attain a certain degree of robustness—that is, in the earlier years of development,

from seven to twelve—peculiarly liable to respond at once to whatever depressing influences may be brought to bear on them. The organism at this age requires only a little to disturb the harmonious relations existing between its components; a mere slight cause will lead to disastrous and lasting effects, and possibly induce a permanent condition of disease which terminates with death alone. The deficient supply of purified air for breathing, together with the injurious influence exerted by organic poisons accumulated in a repeatedly-used medium, are in themselves two potent causes in the production of child ailments; but when there are added to them the further defects of improper drainage and close surroundings, the wonder is that so many children escape illness rather than that so many are overcome by the unhealthy influences they encounter.

The question of children's welfare is of vital importance to the progress of the country, for we cannot forget that "the children of to-day are the rulers of to-morrow." That the poorer and lower middle classes do suffer considerably from the inadequate proportions and wholly improper nature of the apartments in which their education is conducted, will admit of no question; neither that the evil effects following from them are perpetuated in numberless instances through the lives of the unfortunate victims. Weakened physique and impaired functions are the constant sequelæ of school experience; and often enough it puzzles the patient to account for the first onset of the symptoms that, in their development, are a source of serious inconvenience, and in no slight degree may shorten the span of life.

There is but one way to reduce, in the future the extent to which this has occurred in the past, viz., to ensure that all schools are arranged, and conducted with a view to the preservation of health and powers. This, moreover, can only be done in one way other than by licensing every teacher to undertake the office of pedagogue; and that is by an efficient system of inspection. Preaching to the public on the folly of sending its young to unventilated school-rooms is altogether a vain proceeding. The British public will send its children where the least money will buy the greatest apparent bargain; and even though it were to certain death, some parents would send their sons to be taught by the teacher with the highest cramming capacity. No question of ventilation or hygiene troubles him then, nor will he hear, as yet, the meaning of these terms in connection with his family. It will not always be so, we fain would hope; and the time, perchance, will come, and come, it may be, soon, when every father's anxious first inquiry will be, on his child's behalf, "Are the sanitary arrangements good?" and not, as is too frequently now the case, "How many did you pass at the last examination?"

The time has arrived for a determined attempt to be made in favour of abolishing all imperfectly-arranged school-rooms; and first among those to be condemned are, we are strongly convinced, the small, stuffy apartments in private houses, which, never intended for the purpose they are put to, are cruelly inadequate to the needs they are called on to supply.

## THE COLLEGIATE VERDICT ON DUBLIN INSANITATION.

THE death-rate of the City of Dublin for the week which ended March 26 was 34·8 per 1,000 of the population. This mortality was lower than that of any week save one since the beginning of February; yet it was *only* about 35 per cent. higher than the mortality in London, Edinburgh, or Glasgow, the reason for the unwonted apparent salubrity of Dublin city being that the zymotic deaths were largely under average. While we congratulate the citizens upon having a little better chance for their lives than they usually enjoy, we must observe that the congratulations under such circumstances are a sufficient justification for the valuable and timely report upon the death-rate of Dublin which has just been issued conjointly by the Dublin Colleges of Physicians and Surgeons. For the first time we have before us a truly unprejudiced exposition of the causes and remedies of the miserable state of Dublin sanitation, and for the first time the apologetic misrepresentations of the Dublin Corporation for the melancholy *status quo* have been extinguished by the authoritative statements and unanswerable arguments put forward by the conjoined colleges. It is in this respect that the report has done, and will do, most good. Long since every one has known what sanitary reforms are needed, and how they ought to be effected; but hitherto the demand for these reforms have been uniformly answered by the Public Health Committee with disingenuous and wholly erroneous assertions that the law at their disposal is insufficient, that the excessive mortality was only visionary because the calculations were faulty, and that the geologic and climatic conditions of the city were chiefly to blame. The Collegiate report sets out with a categorical statement,

"That the existence of an excessive mortality in the city of Dublin is proved beyond a doubt, and that the loss of life and of material prosperity from preventable diseases in Dublin is so serious as to call for immediate action as to its causes, and for the removal of all such deleterious influences as can be remedied."

These assertions the Colleges support with statistical statements which we need not reprint, because, though probably new to most of the citizens, they are familiar to all sanitarians who have given consideration to the state of Dublin. The report then proceeds to demolish *seriatim* the self-deceptive excuses which the Public Health Committee has for years been preaching into the ears of the citizens.

The Colleges are satisfied that the high death-rate cannot be attributed to—

1. A system of registration peculiar to this city.
2. A notable increase in the population.
3. The immigration of sick persons in the provinces.
4. The geological conditions of Dublin, or
5. The climatology of the city.

Upon each of these supposed causes of the high death-rate the Colleges offer the following observations:—

1. The system of registration in force in Dublin is in effect similar to what obtains in cities and large towns of England.
2. There is no reason to believe that any sensible increase in the population of the city has taken place since the year 1871, when the last census was taken. Indeed, the Registrar-General considers it probable that the population has decreased rather than increased during the current decennial period.
3. If it were true that the deaths of immigrants from the provinces were included in the Dublin mortality, that fact

would not render less striking a comparison of the death-rate of the city with that of London and other capitals and large towns, to which immigrants from the country also flock in large numbers for the purpose of seeking medical aid; therefore conclusions based upon such a comparison would not be shaken by such a statement, even supposing it to be true. Moreover, we have it on the authority of the Registrar-General that the deaths of immigrants are deducted from the number of deaths registered in the city.

4. As to the special influences of physical and geological conditions upon the salubrity of Dublin, the College note that in their report the Royal Commissioners express an opinion "that there are no elements in the site, situation, or elevation (of Dublin) to make the climate necessarily unwholesome." The Commissioners consider that "these natural conditions, if properly taken advantage of, may enable the engineer to sewer and drain the city and its suburbs in the most perfect manner known to modern sanitary science, so that Dublin may stand as an example not surpassed in Europe."

5. It is shown in the evidence of Dr. J. W. Moore that the climate of Dublin is in the fullest sense an insular one, extremely equable. It therefore should exercise a favourable influence on the public health. The absence of great heat in summer should diminish the prevalence of, and the fatality from, diarrhoeal affections; and the absence of great cold in winter should diminish the prevalence of, and the fatality from, affections of the respiratory organs.

The Colleges are also of opinion that the period of ten years, upon which the death-rate calculations are based, is sufficiently long to eliminate the operation of weather influences and other exceptional causes of mortality.

The real causes of the excessive mortality of Dublin, the Colleges set out under eleven separate heads which we may abridge by dividing them under the two comprehensive sub-heads, dirt and neglect, as follows:—

1. Dirty tenement houses. 2. Dirty slaughter houses. 3. Dirty streets and ash-pits. 4. Dirty sewers. 5. Dirty cellars. 6. Dirty and drunken lower classes. 7. Neglect to regulate chemical manufactories. 8. Neglect of precautions against infectious disease. 9. Neglect to provide means for conveyance of sick to hospital. 10. Neglect to supervise new buildings.

With these the Colleges group the saturation of the subsoil by disused wells. The first of these causes, the filth of the tenement houses, in which a large proportion of the city population reside, we have ourselves repeatedly referred as the chief origin of the excessive death-rate, and this opinion is thoroughly emphasised by the Colleges. They

Fully concur in the opinion expressed by the Royal Commissioners, that the tenement houses are "the prime source and cause of the excessively high death-rate of Dublin;" a conclusion which is based upon the overwhelming and almost unanimous testimony of the witnesses examined by the Commission. To that testimony the Colleges are justified in adding their opinion to the same effect on behalf of the medical profession in Dublin, whose knowledge of the condition of habitations of the poor, and the results of such condition upon their health is extensive and reliable.

The tenement houses of Dublin, the Colleges consider, are structurally unsuitable for the purpose which they now serve, and they cannot entertain any hope that the health of the poor who inhabit these houses can ever be materially improved except by the demolition of a large number of them.

While recognising the necessity for thorough reconstruction, the Colleges are of opinion that, in the meantime, by due vigilance and by the firm and universal application of the legal powers entrusted to the civic sanitary authority, it is possible to render some of the Dublin tenement houses at least habitable and moderately wholesome, without great delay or any very serious cost to the ratepayers.

In many instances the profits derived by the owners of tenement houses from the letting of those houses are enormous. It was proved before the Commission that a certain owner of this class of property was receiving for a house,

the rental value of which (owing to its state of dilapidation) was only £10, a total rent of £240 a year; and it was further shown with respect to a number of houses taken for the erection of artisans' dwellings upon their sites that the annual rents received were in most cases not less than five times the ratepayers valuation. The Colleges therefore express, in emphatic terms, their sense of the necessity for an immediate, complete, and systematic inspection of these tenement houses by the civic sanitary authority, and for the firm and persistent enforcement of their legal powers until all sanitary improvements which may seem possible have been effected.

It is impossible for us to give place in our columns to following out the evidence adduced by the colleges with reference to the causes of excessive mortality. We must content ourselves with saying that on the authority of the Royal Sanitary Commission, and frequently out of the mouths of the Corporation officers themselves, the colleges prove *seriatim* the existence in Dublin of all the insanitary conditions which we have enumerated, and they wind up their report by putting, in the form of seven practical suggestions, the conclusions arrived at by them upon the evidence before them, these suggestions being neither more nor less than a recommendation to the Public Health Committee to perform, at least, the duty which has been so long and so clamorously urged upon them, and which they have so grossly neglected. That it may no longer be possible for that Committee to escape from discharging its functions upon the plea that it does not possess the requisite legal powers, the colleges give in an Appendix a *resumé* of the sanitary sections of the Public Health Act, from which it seems indisputable that not only has the Dublin Corporation always held in its hands complete authority to reform the sanitation of the city, but that it has been charged peremptorily with the responsibility of using that authority, and has omitted to comply with that mandate.

We cannot more forcibly express our opinion on this subject than by echoing the following words of the conjoint report:—

The Colleges, after careful consideration of all available facts, feel it expedient to give expression to their deliberate opinion that—

The City of Dublin is, and has been, unhealthy in an excessive degree, and its extraordinary death-rate is attributable—not to errors of computation, or irremediable circumstances—but to long-continued disregard of sanitation, and the omission to enforce the legal means provided for a remedy.

The Colleges are further of opinion that—  
The excessive mortality within the city demands from the civic sanitary authority the most firm, energetic, and persevering execution of the powers entrusted to it, to secure even a partial amelioration of the existing evils; and the health of the city will be likely to deteriorate still further unless dealt with by a new and radical method much more vigorous than that which has hitherto been adopted.

If, with this official declaration before it, the Corporation persists in playing at sanitation, it must accept the undivided blame of the disgraceful state of affairs which now exists. Up to a few years ago, when the present superintendent medical officer of health was appointed, the Public Health Committee made hardly even a pretence of doing anything; since then as much has been achieved as can be expected from a committee which is indifferent, a chief medical officer who has a dozen iron in the fire, a staff of medical sanitary officers who are paid as little as possible for doing as little as possible

and an utterly insignificant body of sanitary inspectors and other subordinate officers. This state of things must not continue. The responsibility of the Corporation for the abominable and fatal condition of the city of Dublin has been fairly placed on its shoulders, and it is, we hope, not likely that public opinion will again sleep upon the question until, as the Colleges declare, the insalubrity of the city of Dublin is dealt with "by a new and radical method much more vigorous than that which has been hitherto adopted."

### TYPES OF BEAUTY MEDICALLY CONSIDERED.

THE types of female beauty, by English artists, exhibited last year at the Graphic Gallery, attracted so much public attention that a similar commission was given to several distinguished French artists, and the fruits of their endeavours to portray ideal loveliness, are now on view in the Strand, side by side with the pictures of their English brethren. Most Englishmen will think that British art does not suffer by the comparison thus instituted, and that for purity, grace, intelligence, and moral elevation, the "dreams of fair women" of the twelve insular artists who contribute to the gallery, vastly transcend those of the six continental artists who have supplied materials to it, even though they may think at the same time that the former have fallen short of their highest possibilities, and have put on the canvas veritable portraits, rather than ideal types.

The French contributions to the Graphic collection are not free from that pathological taint to which we called attention last year, as deteriorating materially in the eye of the physician and physiologist, and even in that of the shrewd but unscientific observer, from the merits of more than one of the English pictures. Two of the French beauties, those of M. Carolus-Duran, and Pierre Auguste Cot, may be said to be in vigorous health, and of robust constitution, but the other four beauties display more or less morbid tendencies or bad health. M. Paul Baudry's conception of female beauty involves a wasting disease in an advanced stage, and physical debility and mental exhaustion, that it is painful to witness. The emaciated and ghastly woman whom he paints is quite unfit to maintain the erect posture in which he has cruelly placed her, and ought to be recumbent in bed. Her wan features, pinched nose, everted lips, filmy eyes, and vacant expression, speak of bodily and mental prostration, and an early grave, and do not even give assurance of a bygone and faded charm. M. Gustave Jaquet's specimen of *beauté perfection* again is also of spare habit and sickly look, suggesting by her swarthy complexion and general bilious appearance, some hepatic derangement of a chronic nature. She has endeavoured to disguise her condition by the use of rouge, and the assumption of an arch expression, but her malady shines through, and is not even contradicted by the redness of her lips, of which the upper one projects preternaturally. The queen of beauty of M. Jules Goupit stares from the canvas with an impudent—not to say brazen—self-assertion that consorts ill with her pale pasty complexion, and evident *ischæmia*. Mentone would be a safer place of

abode for this large-mouthed and broad-cheeked young lady than London during the season of north and east winds. Her neighbour, who embodies M. Henri Lévy's best thoughts of comeliness, labours under mental trouble or malignity, and carries danger in her side-long glance. Fair hair, blue eyes, delicate flesh tint, and noble lineaments, fail to make her attractive, for they cannot dispel the repugnance engendered by her hard and vindictive expression, and by the want of anything approaching to tenderness in her countenance and bearing.

M. Pierre Auguste Cot has drawn his inspiration from sunny Languedoc, and paints for us a pleasing brunette not at all *spirituelle*, but firm and practical—a woman sound in body and mind, not without strong passions, which are disciplined, however, by a living faith, and by a powerful will. She presents to us a type of beauty which, if not of the highest, is still worthy of admiration, as being human and serviceable, and free from all mawkish sentimentality. M. Carolus-Duran has gone even further a-field than M. Cot for his model, and depicts a bouncing Circassian maiden, with round dimpling face, florid complexion, plump limbs, and saucy expression. The Circassian is in high health unquestionably, and in high spirits too, born of her proud consciousness of her own fascinations.

The suffrages of the French artists represented in the Graphic Gallery are given in favour of fair hair and eyes, as were those of the English artists last year, a fact somewhat remarkable, for blondes are not so numerous in France as in England. Of the six French types of beauty, four have blue or grey eyes, and two dark brown eyes. Four have fair or light brown hair, one dark brown, and one black hair. The treatment of the hair by the French artistes decidedly leans to dishevelment, five ladies having rough untutored locks, and only one a comparatively calm *coiffure*. Large hats are also in vogue in French studios, three of the ladies being adorned with these appendages. In all the ladies in whom the ears are visible—five out of six—the lobes are long and pendulous. In one case only is incipient bronchocele discernible. Long necks are universal, and so is precision of outline in the lips, which, in a majority of instances, are inclined to fullness.

## Notes on Current Topics.

### Lord Beaconsfield.

ON inquiry we learn that the asthmatic attacks from which Lord Beaconsfield has been suffering have considerably mitigated in their intensity. He is suffering now from bronchitis, extending into the smaller tubes, accompanied by viscid secretion difficult to remove. The heart, both structurally and functionally, is but little affected; and though there is a small portion of albumen in the urine, the specific gravity is 1015 to 1016; and there are no casts. The pulse ranges between 80 and 90, and the temperature seldom reaches 100°. The usual treatment is being adopted, consisting of ammonia, squills, mercurial alteratives, &c. The prognosis in such a case must tend to be unfavourable, seeing the advanced age of the illus-

trious patient—how much physical and mental exertion he has gone through, and knowing how readily in cases such as this sanguineous congestions and the accumulation of viscid secretion tend to block up portions of lining, and to interfere with respiratory process, his lordship's patience and endurance in this very severe illness are very remarkable.

#### Professor Turner on Dental Licensing.

THE General Medical Council may, perhaps, consider it allowable that it should proceed to legislate on dental questions without making itself acquainted with the law and practice of Dentistry under the new Act; but, if it be considered unnecessary for the members to work themselves up in the subject before they give judgment it is, at least, prudent for them to refrain from public speech which displays their ignorance. We find in the *British Journal of Dental Science*, for March 15, the report of a speech delivered by Professor Turner at a dinner of the Edinburgh Odonto-Chirurgical Society, in response to the toast of "The General Medical Council." The proposer of the toast should, of course, say something civil, so he expressed his opinion that they "as dentists might be thankful that they had been taken under the care of so venerable (*sic*) a body as the General Medical Council. He had no doubt that that body would care for them in every particular, and that their dental degrees would be in all cases worthy of the name." Professor Turner does not seem to have realised that the speaker must have been "poking fun" at the representative of a Council which had "cared for the dentists in every particular," by flooding their profession with uneducated *canaille*, for he gravely thanked the gentleman, and proceeded to give some collegiate statistics. The English College of Surgeons, he said, had within a year licensed eighteen dentists with curriculum, and only one without; while the Glasgow Faculty and the Irish College of Surgeons had passed, respectively, thirty-four and fifty-five without curriculum, and none with. Professor Turner "did not profess to give an explanation of the fact, but thought it was worthy of thought and consideration," from which it appears that he is not aware that the Irish College and the Glasgow Faculty have, since the passing of the Act, not yet completed the "year of grace" allowed for the admission of dental licentiates on examination only, and, therefore, are not yet authorised to require a curriculum. They are, in fact, passing through the preliminary stage which the London College passed through many years ago; and after August next, they will be in exactly the same position as that College. It would seem reasonable that Professor Turner would have asked instruction upon these facts from some one who knows something about dental licensing before passing an implied censure on these Colleges.

#### The Faraday Lecture.

PROFESSOR HELMHOLTZ delivered the Faraday Lecture at the Royal Institution, Albemarle Street, London, on the occasion of the triennial festival of the Chemical Society, which was held on the 5th inst. The subject was "On the Modern Development of Faraday's Conceptions of Electricity." The learned Professor will

afterwards proceed to Dublin, where he has undertaken to deliver the same lecture on this day (Wednesday) week at the Royal Dublin Society. The Council of the Royal College of Surgeons in Ireland have determined to present him with the Honorary Fellowship of their College. This honour, which has been very rarely conferred, is granted, under the authority of the College Bye-Laws, only to "such persons as have eminently distinguished themselves in the sciences of surgery or in any of the branches of knowledge auxiliary thereto." By his discovery of the ophthalmoscope alone, Professor Helmholtz has well merited all honour with which it is in the power of the College to distinguish him.

#### Resection of the Stomach.

BILLROTH's remarkable employment of "heroic" surgery on Jan. 29, when he excised a considerable portion of the stomach, including pylorus, in a woman suffering from cancer of that organ, was so successful that he has twice since repeated the operation. These latter cases, however, were unsatisfactory, one living but eight days after; the other only twelve hours. The original operation was performed with the first intention of exploration simply; an incision along the border of the right false ribs, immediately above the tumour, previously recognised as a large movable mass at the edge of the pylorus, displayed it covered by epiploon and adhering to the transverse colon. It was found to be a considerable growth, and its entire removal was effected by making two incisions, one towards the middle of the lesser curvature, and the other beyond the pylorus, in the healthy duodenum. Immediate and complete adaptation of the cut surfaces took place, and sutures put into them were retained with a facility that is among the most marvellous results of the undertaking. The abdominal wound was closed by sutures and antiseptic dressings, but no drainage tube was employed. Two days after the operation, the patient took food by the mouth, and on the eighth day the suture were removed from the abdominal wall. The favourable progress was not interrupted in this case, convalescence having set in, and solid food having been resorted to without any disastrous consequences. The patient, two months after, continues well; and the success of the operation in her case apparently indicates its feasibility in that class of diseases of which hers was an example.

#### Testimonial to Dr. Habershon and Mr. Cooper Forster.

THE movement initiated some time ago to present the late senior medical officers of Guy's Hospital with a testimonial of the admiration in which they are held by past and present Guy's men, resulted in the fulfilment of the design on Monday week. The presentation was made at the rooms of the Medical Society of London, Mr. Lund, of Manchester, presiding. A very considerable gathering took place, and among those present were several well known members of the profession, including Prof. Odling (Oxford), Messrs. Henry Morris and Durham (honorary secretaries to the Testimonial Committee), &c. The subscriptions, which were limited to one guinea, amounted to a considerable sum, and were put to purchasing two handsome epergnes, one, together with an album contain-

ing the names of subscribers, being presented to each of the two guests of honour. Subsequently to the presentation ceremony, there took place a dinner at the Langham Hotel, where over fifty gentlemen met to do honour to Dr. Habershon and Mr. Cooper Forster, in whose entertainment also this part of the proceedings was arranged. The whole affair was eminently successful.

### The Dalrymple Home.

It may be remembered that in our account last year of the meeting held to consider the best mode of carrying out the provisions of the Habitual Drunkards Bill, 1879, we explained the efforts being made to found a home to which recognised dipsomaniacs might be sent. The establishment of such a retreat has as yet been found impossible, and in furtherance of the aim a meeting will be held at the Mansion House, the Lord Mayor presiding, on May 17th, at 3 p.m. Attempts have been made before this to make private "retreats" remunerative, but in vain, Dr. Forbes Winalow having, at considerable loss, kept one open for some time. The meeting called for May will, it is hoped, call forth sufficient voluntary assistance to enable the committee who have the question in hand, to found at an early date the first Dalrymple retreat for habitual drunkards, and maintain it efficiently during an experimental term.

### Inherited Memory.

THE anti-vivisection fraternity will find in *Nature* of March 31st a distressing instance of the callous unconcern with which their nicest prejudices are outraged by the class of beings whose intelligence is not swamped by the maudlin sentimentality of ignorance. Speculating on the probability of memory being an inherited faculty in animals, and on the possibility of definite experiences being transmitted from parent to offspring, Mr. W. Matien Williams suggests the following experiment. "By means of a small Leyden jar, moderately charged, startle both the father and the mother of an intended forthcoming generation of puppies. When these are full grown, and away from their parents, observe whether they are at all disturbed by the sight of a bottle or a Leyden jar, care being taken that the bottle is never shown to the parents in the presence of the offspring." The excruciatingly painful nature of the proceeding for the unhappy dog, will at once commend itself to the pitying sympathy of the Anti-vivisection Society, and possibly they will need only this hint to take some active steps in the matter. Especially since Mr. Williams, in the most determined fashion, continues "a single experiment will not be sufficient. It should be tried by several. There is no more cruelty involved than in an ordinary practical joke. It is not the pain of the shock, but its startling mystery that frightens the animal, especially if the shock is given by placing the jar on a piece of tin-foil or sheet metal, and allowing the dog spontaneously to investigate by sniffing the knob of the jar, while his fore-feet are in communication with the outer coating. Under ordinary circumstances the dog obtains through his nose much information concerning the properties of things before he actually touches them, but in this case his whole life experience is contradicted by the mysterious, inodorous, diabolical vitality of the vitreous fluid. A bottle thence-

forth makes upon the intellect of the dog an impression similar to that which a sheeted broomstick in a churchyard makes upon the similar intellect of a superstitious rustic." The observations suggested in this letter may be almost as easily conducted on the human animal *mutatis mutandis*, and it is a subject altogether well-deserving the attention of the practical psychologist.

### Portable Home-Baths.

F.R.C.P. in the *British Medical Journal* suggests that advantage would accrue from a revival of the custom formerly prevalent, of supplying baths and attendants with everything complete, at the homes of patients who would be benefited by the use of these therapeutic aids. F.R.C.P. advises the formation of a company to work the scheme thoroughly, and there can be little doubt that, ably arranged, it would be a remunerative undertaking. Many practitioners will echo the words of F.R.C.P., and wish success to his proposal. He says, "my experience—and I have little doubt that other practical physicians would agree with me—is that few houses contain the necessary arrangements for the easy administration of baths; and, even if there be a bath-room, it is rarely in such proximity to the patient's room that it is readily available in sickness. In the majority of cases of severe disease, the bath ought to be placed at the bedside, so that the patient may be lifted directly from the couch into the bath, and *vice versa*. The difficulty of filling a portable bath, which may be said never to be at hand in private houses, is great, apart from the inconvenience of the noise and excitement unavoidable when ordinary servants are required to carry up thirty or forty gallons of hot and cold water to a second or third floor. Having in former years often, both in my own house and for my private patients, employed the *bains à domicile*, the absence of which in London I now deplore, I can speak with confidence of the immense convenience of such an arrangement as then existed; and I would urge that you would confer a real boon upon sick people and their medical attendants if you were to draw the attention of capitalists to the present defect in our social economy. If there were a proper organisation of home-baths, the present state of our knowledge on the subject would render it necessary that the institution, which supplied them, should also have a greater or less number of well-trained assistants, who should be conversant with the use of the thermometer, with the importance of the various influences exercised by various temperatures, with the power of reducing or elevating animal heat by the artificial variation of the bath-temperature while the patient was immersed, with the effect and mode of administration of the various modes of manipulating the body while in and after the bath, and perhaps also with the administration of medicated and galvanic baths."

IN the principal foreign cities, the rates of mortality, according to the latest weekly official return, were:—Calcutta 25, Bombay 32, Madras 42; Paris 31; Geneva 16; Brussels 25; Copenhagen 25; Stockholm 28, Christiania 23; St. Petersburg 51; Berlin 22, Hamburg 25, Dresden 24, Munich 29; Vienna 32; Buda-Pesth 35; Rome 29; Naples 25, Turin 37, Venice 31; New York 30, Brooklyn 25, Philadelphia 22, Baltimore 19.

**Lord Beaconsfield's Medical Attendants.**

It would not be fair to Dr. Quain, nor good for the profession, if we were to refrain from noticing the circumstance of his association with a homœopath in attendance on Lord Beaconsfield. We cannot but regret that the public should be the spectators of an apparent fraternisation between so distinguished a physician and a gentleman of Dr. Kidd's medical creed, and we do not doubt that the most will be made of Dr. Quain's supposed recognition of the homœopathic schism by those who would desire to make scientific medicine ridiculous and inconsistent. But strict as we would wish to be in maintaining the line of demarcation between the scientific physician and the homœopath—which line, in our view, is coincident with the distinguishing limit between professional honesty and the reverse—we acknowledge that special circumstances occasionally arise which justify a temporary and guarded communion between these parties, and we fully believe that Lord Beaconsfield's illness created these special circumstances.

Dr. Quain, we believe, at first refused to consult with Dr. Kidd, but on the assurance that Lord Beaconsfield was not under homœopathic treatment (though attended by a professed homœopath), and on the advice of those highest in the profession, he eventually felt bound to obey Her Majesty's command, and visit the distinguished patient. The situation was a difficult one, and we imagine the public would have been very angry if so valuable a life as that of Lord Beaconsfield had been imperilled even for a moment by an incompatibility of practitioners, which would not be clearly understood. Dr. Quain elected to sacrifice his own feelings rather than incur the responsibility of refusing his aid when it was called for by the Queen, and urgently needed by one of England's greatest statesmen. The circumstances—as we have said—had no precedent—and will give no reason for the same course being pursued in other cases; and we feel bound publicly to acquit Dr. Quain of any avoidable infraction of professional propriety, and to approve of the advice on which he acted.

**Fees for Inquests to Prison Surgeons.**

We learn that the dispute in reference to the fee for medical evidence at an inquest upon the body of a prisoner, to which we referred last week, has been decided, without recourse to law, in favour of Dr. Kinkead, who attended the Grand Jury, and laid before them the legal aspects of the question, as set forth by us last week. Notwithstanding a letter from Dublin Castle to the contrary, the Grand Jury paid the fee, thus, for the second time, recognising the validity of the prison surgeon's claims.

**The Notification of Infective Disease in Dublin.**

We publish to-day a report of the speech of Mr. Edward Dwyer Gray in moving the second reading of his Bill. That measure was read a second time without opposition in consequence of the absence from the House of Dr. Lyons, M.P., to whom the Irish Medical Association had entrusted the resistance to it, but the alteration

of the Bill in Committee was reserved by the Government when they allowed it a second reading.

As to the demerits of the Bill we shall say nothing at present, our only purpose being to express our great surprise that Mr. Gray should have misled the House as to the coercive nature of the Bill. We must assume that a report communicated by telegraph from the House to Mr. Gray's own paper is a correct record of what he said, yet we find therein the statement that "the Bill gave no new power whatever," and that it "did not interfere with the interests or convenience of any section of the public," and again, "no additional powers were sought under the Bill, it asked for no compulsory powers nor did it interfere with individuals." We cannot hesitate to stigmatise these assertions as mis-statements which any one who reads Mr. Gray's Bill must necessarily detect. Mr. Gray is perfectly well aware that his Bill gives to the Dublin Corporation and every board of guardians in Ireland which pleases to accept the authority, the "new power" to compel every medical practitioner within its jurisdiction, by means of a police court prosecution and a £5 penalty, to act as notifier of infective diseases whether he likes it or not. We, therefore, do not hesitate to declare the statement that the Bill does not interfere with the interest and convenience of any section of the public to be totally inaccurate, and calculated to mislead Parliament, who may, on the faith of such a representation, be induced to pass a Bill which they would not tolerate if they knew its nature.

THE rates of mortality last week in the principal large towns of the United Kingdom per 1,000 of the population were—Salford 17, Norwich 17, Nottingham 17, Birmingham 18, Wolverhampton 18, Brighton 18, Sheffield 20, Bristol 20, Bradford 20, London 21, Leicester 21, Manchester 21, Newcastle-on-Tyne 22, Sunderland 22, Oldham 23, Hull 23, Edinburgh 24, Glasgow 24, Leeds 25, Portsmouth 25, Plymouth 26, Liverpool 28, and Dublin 34.

At the fortnightly meeting of the Metropolitan Asylums Board, on Saturday last, the returns showed that the total number of small-pox patients in the several hospitals of the managers had increased since the previous fortnight by 19. The cases under treatment numbered 881, and 49 beds were still available. The number of fever patients under treatment was 179, showing a decrease in the total number under treatment since the previous fortnightly returns of 62.

**Scotland.**

(FROM OUR NORTHERN CORRESPONDENT.)

MEDICAL COMPETITION IN GLASGOW.—The correspondent of a contemporary (the *Lancet*) in referring to the recent extensive changes which have taken place in the ranks of the profession in Glasgow descants upon the number of candidates for "the medical officership to an insurance company," and states that "it is a noteworthy fact the President of the Faculty of Physicians and Surgeons is canvassing as a candidate for it." This is doubtless intended as a "dig" to the

aforsaid President. We cannot regard it as personally merited. If it be a fact it reflects rather on the state of the profession, than personally on the gentleman in question. The medical profession is overcrowded in many large cities, and notably so in Glasgow, not relatively to the population, but to the amount of paying work to be got honestly, by the excessive so-called "charitable" work which cuts in so unjustly on the profession, that if a £5 appointment is vacant there may be fifty candidates. We are informed that the medical officership of this "important insurance company" may be worth from £15 to £20 per annum, and that there are nearly thirty candidates for it! No one who knows anything about the humiliation of canvassing for anything in Glasgow, would submit for one moment to it, unless impelled by necessity; and this necessity *does* arise from the panpering and demoralising influence referred to. If the President of the Faculty is thus compelled to go through so much dirt to so little dignity, he has our cordial sympathy. It might be guessed with a strong probability to accuracy that the paragraph in question has been written by some one connected with these professionally demoralising agencies, and who, with more money than brains, has been, possibly, through social influence, pitchforked into a position, in which he is neither qualified to instruct, nor personally fitted to adorn.

EDINBURGH UNIVERSITY.—CLOSE OF THE MEDICAL CLASSES.—The different classes of the Medical Faculty of the University of Edinburgh were closed on the 31st ult. In all of them, with the exception of that of Pathology, the closing proceedings were almost entirely confined to the distribution of prizes, being University medals and other certificates. In the class of Midwifery Professor Simpson expressed the hope that by next winter session they would be able to take up work in the new medical buildings. In the Pathology class, which during the session has been conducted with such conspicuous ability by Dr. D. J. Hamilton in room of the late Professor Sanders, after the distribution of prizes an address, signed by 260 students, was presented to Dr. Hamilton by the senior medallist. In their address the students testified to the highly efficient manner in which Dr. Hamilton had performed the duties which had been so unexpectedly imposed upon him, of interim Professor. In reply, Dr. Hamilton, after alluding to the lamented death of the late Professor, expressed his pleasure at the honour done him by the students, which he took as more than a sufficient recompense for the arduous labours of the past winter.

GLASGOW ROYAL INFIRMARY SCHOOL OF MEDICINE.—The winter session of this school terminated on Thursday, the 31st ult., when the various prizes were presented to the various students. In the absence of the Lord Provost, Mr. Wm. McEwen proposed that Dr. Scott Orr should preside. On taking the chair Dr. Orr said he had come amongst them quite unprepared to make any speech. He stated that the establishment of the school had been a great boon to the students. There was a movement to amalgamate this institution with the Andersonian College. On this matter he did not intend to express any opinion.

GLASGOW UNIVERSITY COURT.—At a meeting of this Court, held on the 31st ult., present—The Principal, Professor Berry, Dr. J. A. Campbell, M.P., Mr. King, and Dr. Kirkwood, Dr. Hector C. Cameron, of Glasgow, was appointed Examiner in Surgery for the next four years; Dr. Donald Fraser, of Paisley, to be Examiner for the same period in Medicine and Clinical Medicine; and Dr. Alexander MacAlister, of Trinity College, Dublin, to be Examiner for the same period in Physiology and Pathology. What Dr.

Donald Fraser's pretensions to this position are, appear to us enigmatical. He is a graduate of the University of Glasgow of 1867, but we have never heard that his reputation extends beyond the suburb in which he practises. This appointment is perfectly in keeping with one or two recently made in Glasgow.

ANDERSON'S COLLEGE.—The Medical Session at Anderson's College was brought to a close on the 1st inst. Prizes and certificates were distributed to the students who had distinguished themselves. Mr. John McGavin occupied the chair, and was supported by the "Professors," several of the "Philosophers," and other Trustees of the School. After a free indulgence in the vulgar horse-play, which usually characterises the young "gentlemen," who are to be the future practitioners of medicine, the chairman congratulated the meeting on the continued prosperity of the School. Its fame was not local, but world-wide. Professors Morton and Lindsay addressed the audience in a similar strain, and on a vote of thanks being accorded to the chairman the meeting terminated.

THE CHAIR OF PATHOLOGY IN THE UNIVERSITY OF EDINBURGH.—The appointment to this important chair continues to create the liveliest interest in Scotch medical circles. The question at present agitated is whether it is expedient that the chair should be purely a scientific one, *i.e.*, dissociated from private or hospital practice; or should be held by one engaged in private and public practice. On the whole, we think the duties of this chair would be more efficiently discharged by one devoting his whole time to the subject. In support of this view a memorial to the subjoined effect has been presented to the curators by a large number of the senior students of the University:—"It becomes year by year more manifest that the rational treatment of disease is mainly founded upon an accurate acquaintance with pathology. Without this knowledge of the altered structure of the body in disease there can be no rational treatment—nothing but symptoms learned by rote, and treated empirically. In the past the conviction that this knowledge was wanting was the encouragement to the growth of charlatanism, pretence, and quackery, which have hindered so much the recognition of the true worth of medicine. From this it is obvious that a thorough training in pathology is absolutely essential to the student of medicine. But the advance of pathology during the last ten or fifteen years has been so rapid, and so many new means of research have been discovered, that it is only by incessant work, direct observation, and single-hearted devotion that anyone can keep abreast of the advance of the science in all its details; and no intellect, however powerful and untiring, can at once combine an unremitting attention to the teaching of this important subject with the cares and duties of a large practice. To carry on, then, such toilsome researches, to exhibit the processes by which they are carried on, and to teach the results, requires a physician willing to devote his whole time to the special study of pathology."

THE SURGEONCY TO THE WESTERN INFIRMARY, GLASGOW.—Exception is taken by the correspondent of a contemporary to Dr. Cameron's candidature for the appointment of Surgeon to the Western Infirmary, Glasgow. We do not think the objection well founded. Dr. Cameron has gone through the drudgery of the subordinate position in dispensary practice, and has had considerable experience as Surgeon to the "Royal." He is, we believe, a fair operator, and a gentleman of a liberal education. It is high time the farce of inviting candidates by public advertisement, when the appointment is already virtually decided upon, should

be terminated, and on these and personal grounds we wish well to the candidature of Dr. Cameron.

**HEALTH OF EDINBURGH.**—For the week ending Saturday the 26th ult., the deaths in Edinburgh rose from 81 to 105, with a death-rate of 25 per 1,000. This is to be accounted for by the unusual prevalence of chest diseases owing to the severity of the weather—at least half the mortality being due to that cause.

**HEALTH OF GLASGOW.**—For the week ending with Saturday the 26th ult., the death-rate of Glasgow was 24 per 1,000 per annum.

**PAISLEY.**—On the 28th ult. the annual meeting of the subscribers to the Paisley Infirmary was held in the Museum, Mr. Russell (ex-treasurer for the burgh) in the chair. The directors were elected for the ensuing year as follows: Messrs. Thomas Coats, William Polson, Hugh Macfarlane, David Melville, Alexander Begg, John Kerr, James Arthur, M. Hodgart.

**TRICHINÆ IN PORK.**—The Board of Supervision has sent to each local authority in Scotland the circular and memorandum which have been issued by the Local Government Board to the sanitary authorities in England and Wales, respecting the alleged existence of trichinæ in the flesh of swine. It states that "inasmuch as the meat infested with these worms cannot be recognised by any popular test, and the worms themselves can only be detected by careful microscopic examination, it becomes important to take precautions against harm to man in the case of meat from all pigs. The only known means of avoiding disease in man from this dangerous quality of meat from pigs is by very thorough and efficient cooking. If there is reason for thinking a particular sample of meat to contain the parasites, it ought not on any account to be eaten, no matter how it is cooked. Hams, sausages, and like articles, whether or not they have been smoked or salted, should never be eaten in the raw state. To be efficient for the required purpose, the cooking of pork, of ham, of bacon, and of other articles should be prolonged for about half as much time again as is customary. The smallest joint should be cooked for not less than an hour; and whatever be the size of the joint, it should have not less than half an hour's cooking for each pound of meat. No part of a joint that is seen to have an underdone portion in it should be eaten. In boiling hams or pork, the meat should be put into cold or lukewarm water, and the period of cooking should be reckoned from the time when the water boils.

## Correspondence.

### VACCINATION FROM THE CALF IN LONDON.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR.—Some years ago, after a visit to the International Medical Association at Brussels, I narrated in the Medical Society of London and in some of the journals the great success of animal vaccination in Belgium. Since then the practice has become generalised throughout Europe until England, or at least London, has been nearly the only place where there has been no chance of having a patient vaccinated direct from the calf. Dr. Brown, of Finsbury Circus, and others, indeed tried for a term to carry on calf vaccination, but found it too expensive, and too little supported by the public; so that until now I have waited in vain to see the plan carried out and with a fair prospect of success.

To-day, however, I have had the pleasure of visiting a most admirably conducted calf vaccine establishment in the Marylebone Road (228), the private venture of Dr. Charles Renner, M.R.C.S., Eng. of Hamburg, and I would venture to predict that the latest attempt to introduce the practice of

animal vaccination into London will succeed, if only the public spirited and able gentleman who conducts it be a little assisted by the profession and the public at the commencement, which I think will be the case.

Dr. Renner at present inoculates two calves weekly with lymph originally derived from the calf vaccine establishment at Rotterdam, each calf being inoculated on two successive days. Thus, the calf which I saw to-day, Monday, March 28, had been inoculated on Wednesday a certain number of times, say 20, and on Thursday a similar number of times. As the vesicles furnish lymph on the 5th day after the last inoculation he can vaccinate from the first 20 to-day, and will vaccinate from the other twenty to-morrow. The other calf vaccinated on Friday and Saturday will furnish vaccine on Wednesday and Thursday; and on the two last days of the week, Dr. Renner vaccinates patients at a reduced fee (5s.), from the lymph collected on the previous days, and not used for calf to arm vaccination. He charges a fee of one guinea on the first four days of the week.

Of course, if the process becomes popular and more calves are wanted, more can at once be vaccinated, and thus an unlimited supply of lymph can be obtained *sans peur et sans reproche*.

Dr. Renner is evidently determined to spare no expense or trouble, as he has secured the co-operation of an experienced veterinary surgeon to watch the health of the calves—I advise all who care for the progress of practical hygiene to visit Dr. Renner's clinique at 2 p.m. on the first four days of the week. There they will see a most carefully conducted experiment and one which is destined to take root in the customs of this country.

I am sir, yours, &c.,

CHARLES R. DRYSDALE, M.D.

17 Woburn Place, London, W.C.  
March 28, 1881.

### A PRACTICAL TEST OF THE VALUE OF EMULSIONS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR.—I understand that it was the unanimous wish of the meeting of the Medical Society of London on Monday evening, March 28th, that a thorough trial of the new principle of preparing emulsions of cod-liver oil (suggested by Dr. Fothergill's paper) should be made with a view of testing its therapeutic value. Being myself also desirous of further knowledge on this important subject, I beg you will publish the following offer from me:—

"I shall be pleased to make a donation or present of such emulsion to as many as twelve different hospitals (where a careful trial of it will be made), to the value of at least two guineas to each hospital, and will prepare the emulsion of the finest cod-liver oil, and according to the suggestions of the physicians of the hospitals where it is to be tried, using as the emulsifying agents either bile, or choleate of soda, and extract of malt.

"I can also guarantee to make a permanent and palatable emulsion.

"I hope that twelve hospitals will avail themselves of this offer of a donation immediately. Acceptances of this offer will be attended to in the order in which they are received, until the number of twelve acceptances is reached.

"My object is (as a pharmacist) to learn from the experience of the medical profession the value of bile, choleate of soda, and extract of malt as emulsifying agents in increasing the usefulness of cod-liver oil."

Yours, very respectfully,

S. M. BURROUGHS.

Snow Hill, London, E.C.

P.S.—I make this offer at the suggestion of the Medical Society of London.

### THE COURAGE OF MEDICAL OFFICERS IN BATTLE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR.—As many people are under the erroneous impression that the position of the medical officer in war time is one attended with much less danger, and consequently with less honour, than that of the combatant officers, and as every

opportunity should be utilised to place the matter in its true light before the public, perhaps you will kindly insert in your next issue the following remarks from the special correspondent of the *Times*, which appeared in that journal on the 26th inst. After speaking in highly laudatory terms of the conspicuous coolness of all the officers under a deadly fire, he continues: "Where all were calmly courageous it seems invidious to make mention of any; but Dr. McGann, Army Medical Department, behaved splendidly. He never spared himself for an instant, and when the cry was heard 'pass the word for the doctor,' he quickly made his way to the wounded man, making himself for the nonce the most prominent target for the Boer marksman." The other medical officers are also spoken of in terms of praise.

Yours faithfully,

D. H. CULLIMORE, F.R.C.S.I.,  
Surgeon in H.M. Indian Army.

15a Connaught Square, London, W.

## Literature.

### EXPERIMENTAL CHEMISTRY FOR JUNIOR STUDENTS. (a)

"ANOTHER yet," and still they come. It is, however, pleasant to feel that we are here dealing with a book that the student may rely upon, and which possesses some novelty. Everything that Prof. Reynolds undertakes will sure to be carefully considered, and, besides, emanates from an experienced teacher.

In this book the author generally follows each theoretical description by a series of experiments; no better system could be adopted for instruction. If we are to take exception to any part of this book, it is that the experiments are needlessly repeated, and are too primitive in their character; as an instance we give, page 80, experiments with acids, and alkalies, and salts.

Wherever required this little work is judiciously illustrated by wood-cuts. Prof. Reynolds is fond of taking two, or a few elements, to ring the changes on. No doubt such a system has an advantage for the student, as it does not needlessly confuse things. Most of the physical and chemical illustrations in the book are tacked on to the two elements, oxygen and hydrogen.

### HISTORICAL SKETCH OF THE PROGRESS OF PHARMACY IN GREAT BRITAIN. (b)

JACOB BELL has now been dead many years, and time has added to the bright halo which has gathered round his name. Not so much from striking powers displayed by the man as from a steady and fixed determination to raise the status of pharmacy in England. This historical sketch was written at a time when pharmacy was trying to assert itself (1842). Nothing could be possibly worse than the state of pharmacy previous to that date in England, and it must ever remain a blot upon the general advanced civilisation of that country. The struggles for the emancipation of pharmacy from the thralldom of ignorance and trade interests, is well detailed in the first part of this work, which was written by Jacob Bell. The history of the progress of pharmacy in England since that day may be said to be the history of the Pharmaceutical Society of Great Britain. The story has been well told in the book before us by Prof. Redwood, as a continuation to the first sketch by Bell—one of the foremost soldiers in the fight himself; no better man could have been selected for this purpose. Like all that he does, it is done thoroughly. It places strikingly before us the delicate position that the Pharmaceutical Society was frequently placed in. It, however, always seemed to have come out well, and we doubt if the public, or the medical profession in England, will ever thoroughly appreciate all that they owe to the Society. There are many anecdotes in this work that will interest the medical practitioner.

(a) "Experimental Chemistry for Junior Students." By Emerson Reynolds, Professor of Chemistry, University of Dublin.

(b) "Historical Sketch of the Progress of Pharmacy in Great Britain." By Jacob Bell and Theophilus Redwood. 1880.

## Medico-Parliamentary.

### HOUSE OF COMMONS.—MARCH 30TH.

#### NOTIFICATION OF INFECTIOUS DISEASES (IRELAND) BILL.

Mr. E. DWYER GRAY rose to move the second reading of this bill, to the principle of which he had not heard the slightest objection taken by any individual. The Bill proposed to give no new power whatever, and it would be construed with the Public Health Act, which conferred certain powers on the sanitary authorities for the prevention of infectious disease. The main difficulty experienced by the sanitary authorities hitherto had been that information did not reach them in sufficient time to enable them to take steps in order to check the spread of infectious disease. His attention had been directed to this subject by the fact that last year, when he occupied the Dublin Mansion House, a very influential deputation waited on him, consisting of the whole medical profession of Dublin, asking that the Corporation of Dublin should see that steps were taken to secure the notification of infectious diseases when it occurred within their sanitary district. The proposal the Bill contained was that the authorities of every sanitary district may apply to the Local Government Board to declare the Act in force within its district. It required the sanitary authority to take the initiative, not the Local Government Board; and then it would be in force in such district, or in whatever portion of it as that sanitary authority may decide, but the identical provisions will obtain in every district in which it may be put into operation. If the bill turned out effective, and did result in checking infectious disease, it would be open to Parliament to act in regard to it in the same manner as it had done in previous sanitary acts, and make it compulsory after it had first been tried as a permissive enactment. He had a large body of evidence to urge in favour of the Bill, but he would not weary the House by going into it. In Dublin, unfortunately, they had had very bitter experience of the way in which small-pox can make its home in a district. For the past four or five years a state of things existed which would be rendered impossible if the sanitary authorities possessed the power conferred on them by the Bill now before the House. It should be understood that this bill did not interfere with the interests or convenience of any section of the public; it did not harass the poor at all. The poor, however the wretched tenements in which they dwelt favoured the spread of disease, were when they were dealt with properly generally tolerably ready to do whatever may be right. The difficulty was their ignorance; and their permitting disease to spread through the members of their families before they are rightly aware of the risk they run by so doing. No additional powers are sought under the bill; it asked for no compulsory powers, nor did it interfere with individuals; it simply provided that notification should be given to the sanitary authorities to take whatever steps for the checking of disease which they are already empowered to take by existing acts. With regard to the details of the bill, he could only say that whatever views the house was disposed to take with regard to them he was quite prepared to accept. (Hear, hear.) In conclusion, he would just mention that recently a joint committee of the Royal College of Surgeons and the Royal College of Physicians of Ireland was appointed to inquire into the causes of the high death-rate of Dublin, and in their report the very first remedy they suggested was the notification and registration of infectious diseases by the sanitary authority.

The SOLICITOR-GENERAL for IRELAND said he entirely agreed with the object of the bill, and therefore the Government would not oppose it going into committee; on the contrary, they would assist. (hear, hear.) But the Government would reserve to themselves the power of amending the bill in committee on the ground that a large and influential medical body in Dublin—the physicians of the King's and Queen's Colleges—were of opinion that some of the details of the bill required to be altered. It was desirable to obtain all the assistance they could from the medical profession to alter and extend the scope of the bill (hear, hear).

### NOTICES TO CORRESPONDENTS.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a distinctive signature or initials, and

avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

**LOCAL REPORTS AND NEWS.**—Correspondents desirous of drawing attention to these, are requested kindly to mark the newspapers when sending them to the Editor.

**A PUBLIC VACCINATOR.**—There are one or two establishments in London for public vaccination from the calf and for the supply of calf-lymph. One has recently been opened by Dr. Renner at 228 Marylebone Road, W. The lymph can be obtained, post free, at 2s. 6d. for one glass-tube, or two ivory points from Messrs. Allen & Hanbury, 37 Lombard St., City, or Mr. Martindale, 10 New Cavendish St., W.

#### COCK'S OPERATION ON THE URETHRA.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—In your issue of 30th March I am reported correctly as having said "that I did not afterwards attempt to establish the continuity of the urethra" in a case in which I performed Mr. Cock's operation; the reason for my not doing so, and which I stated, has been omitted—namely, that the patient was suffering from albuminuria. Kindly insert this, and oblige,  
Yours faithfully,  
27 Great Fitzwilliam Street, Dublin,  
W. J. WHEELER.

April 2, 1881.

**CUTICLE.**—We believe Dr. Balmanno Squire was the first to introduce the practice in this country.

MR. G. S. C.—Unsuitable for our columns.

**ANTI-QUACK.**—The letters which originally appeared in this Journal exposing the nefarious system, have been long since reprinted in book form and have met with an enormous sale.

#### THE DUALITY OF CHANCERE.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—In reference to this subject, now being debated in your columns, will you permit me to state that I have found constitutional symptoms follow soft sores, and been blamed for having assured the subjects that the sores were non-infecting.

Fark Place, Leeds,  
April 1, 1881.

Yours, &c.,  
PHILIP FOSTER, M.D.

**FRANK, BUT NOT FLATTERING.**—The *Students' Journal and Hospital Gazette* is certainly an amusing little journal, characteristic of the class by whom it is supported. There is a *verve et bonhomie* in its correspondence which is refreshing, though at times more honest than polite. As an instance of this may be given the editorial answer to a correspondent in last Saturday's number. It runs thus:—"Your opinion that 'science is all humbug, and there is nothing but classics and mathematics worth a man's knowing,' has, no doubt, been arrived at after a full and exhaustive survey of all human knowledge; and we do not hesitate to believe that you are especially competent to decide the relative advantages of different studies. We shall be glad to see you at an early date if you can make it convenient to call. We never knew but one man of your capacity, and he died—mad."

MR. BARNWELL.—We never give the name of any practitioner for consultation. There is a list of consultants in Silverlock's "Medical Reference Book," but this is manifestly incomplete and unreliable. Any practitioner of standing should be able successfully to treat your case.

DR. CHURTON (Leeds) is thanked.

**PRISON LIFE OF THE CONVICT BUCHANAN.**—Dr. Buchanan, the foster-father of bogus medical diplomas, entered the Eastern Penitentiary at Philadelphia a few days ago, says the *Louisville Medical News*, with his head covered by a sack to prevent his knowing the location of his cell. He had been confined up to that time in the county prison, but now he is a convict in the Penitentiary, fulfilling the sentence passed on him for conspiracy to defraud the United States of his bail. There are other charges still pending against him, and it is not unlikely that, at the expiration of his present sentence, his diploma-mongering may be placed indefinitely in abeyance on other counts.

A CANDIDATE should get Gant's "Guide to the Examinations," the fourth edition, a copy of which has just reached us, contains all the alterations in examinations at the College for the Membership and Fellowship, together with a re-arrangement of the anatomical and physiological preparations in the Museum by Dr. Garvon, Assistant-Curator.

MR. J. B. H.—We shall shortly devote one or two articles to the subject, for which we shall not fail to make use of the information contained in your note.

**IN MEMORIAM—DR. PERLE.**—The following lines have been composed by Sir Francis William Brady, Bart. :—

"Hushed is the voice so lately raised  
In sweetest notes of sacred song;  
Those notes, that God so oft have praised,  
To God, for evermore, belong.  
Cold is the hand that oft has led  
The weary sufferer back from death,  
When, by some lonely pain-racked bed,  
Each moment seemed the last of breath.

Still is the heart, so warm and true,  
That ever beat at Honour's call,  
What'er was Right, 'twas his to do,  
To Duty live, to Duty fall.

**ROYAL COLLEGE OF PHYSICIANS OF LONDON.**—Wednesday, April 6, and on Friday, April 8, at 5 p.m., Lumsian Lectures: Dr. Southey, "On Bright's Disease."

**BROMPTON CONSUMPTION HOSPITAL.**—Prof. Marshall, F.R.S., will deliver two lectures at this Hospital to-day (Wednesday), and on Wednesday next, at 3 p.m., "On Diseases of the Chest requiring Surgical Treatment," to which members of the profession will be admitted on presentation of their cards.

**HUNTERIAN SOCIETY.**—This evening (Wednesday), at 7.30. Comed Meeting.—3 p.m. Dr. Hughlings Jackson will exhibit Cases of Disease of the Spinal Cord.—Dr. Port, "On a Case of Disseminated Sclerosis."

**EPIDEMIOLOGICAL SOCIETY.**—This evening, at 8, Deputy Surgeon-General Joseph Ewart. "On Scrofula, Tuberculosis, and Phtisis in India."

**OBSTETRICAL SOCIETY OF LONDON.**—This evening, at 8, Specimens will be shown by the President, Drs Godson and Cory, and Mr. Alban Doran.—The Discussion on Dr. Barnes's paper "On Missed Labour" will be resumed, after which "A Case of Delivery through an Imperforate Vagina," by Dr. Heywood Smith, and other communications.

**OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.**—Thursday, April 7, at 8 p.m., Living Specimens.—Dr. Hughlings Jackson, "On a Case showing the state of the Discs ten years after recovery from optic Neuritis."—Mr. Waren Tay, "On a Case of Disease at Yellow-spot Region in an Infant."—Report of the Committee on Colour Blindness (presented by Dr. Brailley).

**LINNEAN SOCIETY.**—Thursday, April 7, at 8 p.m., Dr. Cobbold, "On Parasites of Elephants."

**ROYAL INSTITUTION.**—Friday, April 8, at 8 p.m., Prof. Tyndal, "On Conversion of Radiant Heat into Sound."

#### VACANCIES.

Aberdeen.—Medical Officer of Health for the City. Salary, £300. Applications to be lodged with the Town Clerk before April 9.

Carrickmacross Union, Donaghmoynne Dispensary.—Medical Officer. Salary, £100 per annum, and £15 as Medical Officer of Health. Election, April 11.

Dundalk Union, Barronstown Dispensary.—Medical Officer. Salary, £120 per annum, and £25 as Medical Officer of Health. Election, April 7.

Hertford General Infirmary.—House Surgeon and Secretary. Salary, £100, with board. Applications to the Chairman of the Board before April 22.

Lancaster Union.—Medical Officer for the Southern District. Salary, £45, with the usual extra fees. Applications to the Clerk of the Union before April 15.

Liverpool Royal Infirmary.—Resident Medical Officer. Salary, £100, with board. Applications to the Chairman of Committee before April 20.

Salisbury Infirmary.—House Surgeon. Salary, £100, with board. Applications to the Secretary before April 21.

Sunderland Infirmary.—Two House Surgeons. Salary commencing at £90 and £80 respectively, with board. Applications to the Chairman of the Medical Board before May 4.

#### APPOINTMENTS.

BLANDFORD, J. W., L.R.C.P.Ed., M.R.C.S.E., Medical Officer for the Norton District of the Stockton Union.

CARDEN, G. A., M.R.C.S.E., Honorary Medical Officer to the Branch Dispensary of the Cheltenham General Hospital.

CATHOART, C. W., M.B., F.R.C.S.E., Lecturer on Anatomy in the Royal College of Surgeons, Edinburgh.

CHAPMAN, J. H., M.K.Q.C.P.I., L.R.C.S.I., Medical Officer to the Hospital for Incurables, Dublin.

HAYWARD, J. B., M.R.C.S.E., Medical Officer for the All Saints' District of the Maldon Union.

JEFFREYS, R., M.R.C.S.E., Medical Officer for the Bampton and Walton District of the Chesterfield Union.

KENNE, F., L.R.C.P.L., M.R.C.S.E., Medical Officer of Health for the Aylesbury Rural Sanitary District.

MOGHEGH, W., M.D., M.Ch., M.R.C.S.E., Honorary Assistant Medical Officer to the Ladies' Charity and Lying-in Hospital, Liverpool.

MEERES, E. E., M.D., M.R.C.S.E., Physician to the Plymouth Public Dispensary.

MALLEY, A. C., M.B., M.Ch., Medical Officer for the Manalaw District of the Ludlow Union.

MATURIN, Dr., Temporary Medical Superintendent of Kilmainham Fever Hospital, Dublin.

#### Births.

DEANE-BUTCHER.—March 30, at 18 Friar Street, Reading, the wife of W. Deane-Butcher, M.R.C.S., of a son.

HAMILTON.—Feb. 7, at Tandragee, South Australia, the wife of T. Kinley Hamilton, M.D., F.R.C.S.I., late of Tandragee, co. Armagh, of a son.

#### Marriages.

DOCKEY.—KNOX.—March 31, John Alexander Dockey, L.R.C.S.I., and Edin., of Usher's Island, Dublin, to Marie Louise, eldest daughter of John T. Knox, Esq., late of her Majesty's Customs.

JONES—HICKS.—April 2, at St. John's, Notting Hill, William Jones, L.R.C.P., L.R.C.S., of Edmonton, to Emily Elizabeth, eldest daughter of George Hicks, Esq., of Royston Villa, Bayswater.

PYE—KIDSTON.—April 1, at 27 Blythwood Square, Glasgow, Walter Pye, F.R.C.S., of London, to Anna, daughter of J. B. Kidston, of Glasgow.

#### Deaths.

DOVE.—March 31, at St. Stephen's Square, Bayswater, W., W. Watson Dove, L.R.C.P.Ed., late of Alexandria, aged 33.

MERRIDMAN.—March 24, at West Lodge, Putney Common, after a few hours' illness, John Merridman, M.R.C.S.E., L.S.A.L., Apothecary Extraordinary to the Queen, aged 80.

SAUNDERS.—Feb. 23, at Weston-super-Mare, Thomas Dudley Saunders, L.R.C.P., M.R.C.S.E., of Sion Hill, Bath, aged 35.

WEBB.—March 29, at the Vicarage, Heckmondwike, Yorks, Edward Charles Webb, L.R.C.S.Edin., aged 32.

WHEATLY.—March 24, at Gainsborough, Torquay, Edward Wheatly, M.R.C.S.E., aged 61.

### THE LUMLEIAN LECTURES ON BRIGHT'S DISEASE.

Delivered before the Royal College of Physicians, London.

LECTURE I.—PART I.—Delivered APRIL 1ST.—(Continued).

By REGINALD SOUTHEY, M.D. Oxon., F.R.C.P. Lond., Physician to St. Bartholomew's Hospital.

In reviewing, however, what was done at this date, it would be unjust not to mention a very elaborate paper communicated by Mr. Toynebe, to the "Medico-Chirurgical Transactions," in 1846, on the intimate structure of the human kidney. Toynebe was most successful in his injections, both of the tubules and of the arteries. Dr. Bright had himself furnished him with a great variety of kidneys in several stages of disease, and very good use he obviously made of them, as his drawings and text prove. He was the first to establish distinctly the existence of intervacular spaces (*vide* "Med.-Chir. Trans.," vol. 29, p. 304) of no inconsiderable size, situated between the blood-vessels and tubuli, and occupied by a substance he named parenchyma. Ruysh had described this as a cellular network, connecting the vessels together. Toynebe recognized the importance of this intertubular parenchymatous network of cells in diseased processes. Those who care to examine his drawings of the tubuli uriniferi (*vide* figs. 2, 6, and 8), will see how entirely they confirm the latest modern views (Dr. Klein) on the size and contours of the tubes. He showed how in the second stage of Bright's disease, when the primary congestion of the organ subsided, the swelling and dilatation of the tubuli, compressed the intertubular capillaries, while the afferent artery to the Malpighian bodies became enlarged to eight or ten times its normal dimensions, and proportionally varicose, and how, in the third stage, the parenchyma became hard, and appeared composed of elongated stellate cells, having fine thread-like prolongations. His views, therefore, formed quite independently of Dr. Johnson, tended to strengthen those of the latter, in his separation of the large anæmic fatty kidneys from the small granular vascular one.

In 1847, Dr. Johnson's second communication to the

"Medico-Chirurgical Transactions" was published, which discussed the inflammatory diseases of the kidney, which he divided into two classes, traumatic and constitutional. The lesions, which he attributes to a constitutional cause, some abnormal condition of the blood, he subdivides into four different types or forms. 1. An acute desquamative nephritis. 2. A chronic desquamative nephritis. 3. Simple fatty degeneration. 4. A combination of fatty degeneration with desquamative nephritis. He showed that in all these forms morbid materials were deposited in the tubules, and washed out of them again, forming casts (Franz Simon's fibrinous threads), which were to be of the highest importance hereafter as indices for treatment and in prognosis.

In the same volume of the "Transactions," vol. xxx., 1847, appeared a remarkable paper from the pen of John Simon, who thought it "indispensable for correct nomenclature, that the name of Bright's disease should be discontinued." He is convinced that there are two forms of disease at least confounded together under this term, for he, too, like Johnson, is an early dissident or dualist. He separates one form of kidney-disease from the other by the nature of the inflammation which sub-tends it. One is an ordinary subacute inflammatory process, the other a scrofulous degeneration.

Subacute inflammation of the kidney might, according to his views, be provoked by exposure to cold, by rheumatism or by gout, by intemperance, by the circulation of various fever poisons in the blood. The products of inflammation poured out into the tubes, led to blocking and bursting of them, and to liberation of inflammatory exudation, as well as of free renal epithelium cells into the parenchyma of the organ, the exudation materials subsequently underwent contraction, the free renal cells developed into cysts. Thus was brought about the small, red, granular multiple cyst containing kidney.

The scrofulous degenerative disease, however, as it had a different etiology, so, too, pursued a different pathological course, which consisted in the successive deposition of fatty materials in the glandular substance, which slowly accomplished its entire disorganisation, and resulted in a large white or mottled kidney. "The mottled kidney," he writes, p. 158, "in an infinitely large proportion of cases remains large and mottled to the end."

That the temperament and health of the individual modifies the course taken by disease in all his organs, who shall gainsay; but the distinctions he drew admit of fixing by no hard and fast lines, and, therefore, as grounds for basing a classification on, do not commend themselves.

But among the many valuable and most suggestive ideas scattered through this careful paper, the following passage proves how thoroughly he realised the fact that the peculiar shape and length and alterations in calibre of the tubuli uriniferi modified the end result of inflammatory processes involving them. Thus (p. 142) "the complexity of the tubules, the narrowness of the canals renders them especially liable to be embarrassed by changes in the physical qualities of their secretions." "The delay, accumulation, and obstruct action, of which suffice to derange the whole microcosm of the (gland) in which they occur."

Even at this early date the thickened state of the renal vessels had attracted attention, as well as what Bright had observed, the associated hypertrophy of the heart. It was not very easy to ascertain who was the first to perceive that the arterial walls of the renal vessels became thickened. Toynebee noticed the fact that in his injections of Bright's kidneys, published in 1846, and Dr. Johnson, in his third communication to the "Med.-Chirurgical Transactions" in 1850 (vol. xxxiii., p. 107), writes to this effect. "The changes of the secreting cells involve imperfect elimination of real constituents of the blood, the nutritional changes, do not go forward properly, and this accessory circulatory force becomes impaired. Hence the tendency is for the blood to dally in the capillaries, and to require additional pump-force from the heart to drive it forward, when, what happens is that the heart becomes hypertrophied, and the walls of the arteries also."

The same fact is dwelt upon by him later on, as a most important factor, in the development and prognosis of renal disease. It is only necessary to call attention to the matter here, as a part of the history of Bright's disease; its importance will claim notice later on.

At this date, *i.e.*, about 1850, Martin Solon's vague name of albuminuria for acute and chronic renal disease was, in England, as in France, creeping into general use; it recognised a fact, and avoided a difficulty; it implied that the kidneys functioned faultily, and hazarded no diagnosis upon the nature of the lesion in them. It left room for an open prognosis to be drawn from observation of other symptoms; it might, or might not, be a serious symptom itself. It must be borne in mind that Bright's disease was a term as yet of very uncertain value. English physicians were quite undecided whether it should be held to comprehend one uniform or a variety of pathological states of kidney.

Dr. Owen Rees now published (1850) a volume on "The Nature and Treatment of Diseases of the Kidney." In this he thoroughly sifted the subject of what Bright's disease consisted in, and what it should be restricted to—namely, degenerative changes of the kidney, which were the result of past or present inflammatory processes.

After ably showing (p. 40) the fallacy of the argument that a general blood-disease should not be found guilty of inducing degeneration or inflammation in one special organ, he writes, but so far as our present knowledge extends, it is in the tissue of the kidney itself that we see those first departures from a normal state which produce albuminuria. Many of the changes observed in the blood may undoubtedly be traced to the condition of the kidney. Dr. Rees was the earliest writer to point out that urine, with excess of earthy phosphates in it, gave a copious white deposit on being boiled, which closely resembled albumen, and had often been mistaken for it. He also showed how to obviate error by the well-known reaction with nitric acid. He was too, I think, the earliest to notice the frequent desire to rise and pass urine at night as a symptom of Bright's disease (p. 59), and the hard, wiry pulse, less elastic than in health, and tortuous, which, if connected with a pallid face, is, as he says, very suggestive of the nature of the malady.

In 1851, Frerichs' monograph, "Die Brightsche Nieren Krankheit," was published in Germany, and carried throughout Europe, the name and discoveries of the great Guy's physician, who had linked together albuminous urine, general dropsy, various pulmonary affections, asthma, bronchitis, and pleurisy, uræmic symptoms, and apoplexy, with a peculiar and insidious pathological degeneration of the kidney, and showed how the kidney disease led to an alteration of the blood, and this alteration of the blood to an hypertrophy of the heart, wholly independent of any disease of its valves.

New and more comprehensive views upon inflammation than those which had hitherto chiefly emanated from the Vienna school, were advancing from the north of Germany. The era of fluxions and exudations, catarrhal, croupous,

and fibrinous, was drawing to a close. Could the pathological alterations, described by Bright as taking place in the kidney, be left to fulfil the old conditions of an inflammatory process? Could it be interpreted by them?

Frerichs describes the pathological events as succeeding each other in the following order. The mischief began in the kidney by a first stage of hyperæmia and exudation into the parenchyma of the gland; it was continued, his second stage, by various metamorphoses which the exudation underwent; it terminated, his third stage, by retrograde changes and atrophy of the glandular substance. One important feature of the second stage, which he illustrates by a woodcut, is the varicose dilatation of the secreting tubes sometimes, as he says, to twice or three times their natural size (p. 28); some portions of the tubes retaining their cell-linings in an apparently normal state, others presenting altered and fatty cells in them, and others, again, being left apparently quite denuded, as Dr. Johnson had described them. He admits that the second stage was that which most frequently fell under observation. He makes an acute and a chronic form of the disease. At p. 58, he shows the objection to Dr. Johnson's inference, that the nature and extent of the degeneration can be diagnosed by the casts, because the diseased process exists in different stages at the same time in the same kidney, and because every variety of cast may be present at one and the same time. He considers the amount of albumen in the urine a measure of the intensity of the exudation process, and applicable upon the anatomical changes in the gland, so much of which is destroyed. As to the effect of the removal of renal epithelium upon the escape of albumen, he pronounces no definite opinion. According to him, the immediate effects of renal disease upon the system are: impoverishment of blood, increase of organic materials in it from impurities, which ought to have escaped, remaining combined in the blood. Among the symptoms to which he calls special attention—and his symptomatology leaves little to be improved upon—he notices the occasional follicular ulcers of the colon (p. 103), and the presence of carbonate of ammonia in blood.

The great novelty of his work was his ammoniæmia theory of uræmia, which may be stated in few words. Urea, he said, as experiments led him to believe, might circulate in great excess in the blood, but would provoke no toxic symptoms, unless it underwent decomposition into ammonia carbonate; and the presence of some special ferment in the blood, as well as of urea, was requisite in Bright's disease for the production of uræmic symptoms. The proclivity of any patient who had renal disease to uræmia could be estimated by the amount of free ammonia in his blood, and its great excess easily be rendered apparent by a glass rod, dipped in hydrochloric acid, fuming freely when brought into contact with ammonia-laden breath. The original experiments were faulty, and his inferences were not justified by his facts. They obtained very little acceptance. Ammoniæmia has been long since relegated to the limbo of unproven physiological doctrines.

Frerichs' book was strongest in its clinical descriptions of the symptoms marking the different stages of renal disease; these are sketched by a masterly hand.

In 1852, Dr. Wilkes published an article, entitled "Cases of Bright's Disease," in the "Guy's Hospital Reports," 2nd series, vol. viii. He began by expressing his preference for the name of Bright's Disease over that of Albuminuria; since renal disease, he found, might exist, and no albumen escape in the urine, and albuminuria might occur temporarily without depending upon any such lesions as Bright had described in the kidney. Bright's disease, he acknowledged, was still very imperfectly understood, pathologically or clinically; but certain well-observed structural changes in the kidney, accompanied by a regular train of symptoms and secondary pathological phenomena, might be vouchsafed to indicate it. He criticised Frerichs' book, and naturally assailed the weak point in his argument. If the small granular kidney was the final stage of one uniform process of disease, successive inflammatory congestions, exudations, and subsequent degenerations and contractions, how was it that so few examples of the intermediate pathological states were encountered? Why was it that no single case was mentioned in which the symptoms betokening the large inflammatory kidney could be traced gradually altering into such as appointed a small granular kidney? or that no case of ascertained small granular kidney is observed as having been preceded by acute symptoms? At p. 238 he writes: "In chronic granular kidney, the urine is often in good quantity, containing no deposits, and may or

may not be albuminous. Dr. Wilks pronounces himself as a very positive dualist, and discriminates two principal forms of Bright's disease—the large, white; the small, granular—and then describes the rarer or lesser varieties, the mixed forms, and secondary forms, of later writers. He distinguishes the red swollen coarse kidney of passive venous hyperæmia; the dense white fibrous kidney (which I shall hope to show hereafter) is the obstructed urinary outlet kidney, and the simple fatty kidney of phthisis. He is the first author I have read who points out plainly that the large white kidney may have two modes of commencement: either by acute general dropsy, or quite insidiously. He is the first to talk of granular kidneys as premature senility; to notice how (*vide* p. 256) "the older the patient is, the more liable is he to granular degeneration of the kidney;" and remarks among the thick tortuous radial artery, the general anæmia, the characteristic pale urine, and the desire to micturate so frequently, as well as the death-tendency by apoplexy or nræmia, in this chronic malady. He compares the changes in the large white kidney to bronchitis in the lungs, which may be recovered from entirely, or may pass on by extension of the inflammatory processes through the parenchymatous tissue of the organ to degenerations analogous to those which take place in bronchopneumonia.

His description of Bright's disease leaves nothing to correct, and little to add to; but he is not much captivated (*vide* p. 274) by Johnson's theory of the mode in which the albumen escapes from the blood, attributing the albuminuria, straightforwardly, to obstruction of the circulation through the tufts and capillaries, and not to its transudation through the tubes, because of their cell-denudation.

In 1852, appeared Virchow's pamphlet, "Ueber Parenchymatöse Entzündung." This form of inflammatory change in the kidneys is thus described by him: the elements of which the actual tissues of the organ are composed swell up, the cells become cloudy, less transparent and more granular, as well as more friable than they should be. The possible issues are in one of two directions: 1. The epithelial elements may soften down into a proteinous jelly or pulp. 2. They may become milky, and undergo fatty metamorphosis. Parenchymatous inflammation in the kidney, he insists, does not exclude the simultaneous occurrence of interstitial hyperplasia. Catarrhal, croupous, and parenchymatous exudation may be combined together, and will then lead to the highest degree of renal degeneration.

Virchow's simple catarrhal affection of the tubuli appears to correspond with Johnson's acute desquamative nephritis; and both allow that this admits, in its slighter grades, of complete recovery. Virchow's croupous nephritis is a graver grade of catarrhal inflammation, in which fibrinous exudations are poured out into the tubules, and block them up; and Virchow advises the attachment of the name of Bright's disease, not to any temporary or transitory affection with albuminous urine, but to those graver and more extended inflammatory changes, which, starting from parenchymatous inflammation, ultimately invade every elemental structure of the kidney, and entail its complete degeneration.

Johnson and Virchow are agreed in what they are describing and what they would call Bright's disease; but they differ widely in the terms they employ to represent the pathological process, and in the method in which they interpret the phenomena. Johnson is a trifle too allegorical with his desquamative nephritis, and Virchow stretches the old-world notion of inflammation prevalent at that time to bursting point with his parenchymatous swelling.

Traube, in his volume on the connection between renal and heart disease, broke fresh ground in 1856, when he distinctly separated the cardiac kidney, *i.e.*, the kidney of passive renal hyperæmia, from the kidney of Bright's disease or primary kidney-disease, and showed that, while valvular heart-lesions entailed kidney-disease in many instances; chronic kidney degeneration, and especially Bright's atrophic kidney, compelled heart-hypertrophy as an almost inevitable consequence. In this work, Traube summed up, with the master-hand of a clinical teacher, the mode of distinguishing the primary from the secondary disease, writing: "In both, the urine is albuminous; but when the renal degeneration is primary, and the cause of the heart-hypertrophy, and the hypertrophy, is adequate to the renal defect, the urine is copious, pale, and generally of low specific gravity, and the amount of albumen in it variable (but seldom considerable); whereas, when the renal degeneration depends upon passive congestion secondary to heart-disease, the urine will be dense,

scanty, and high-coloured, and its albumen contents large in amount." His pathological description of the two kidneys is equally good. "The kidney secondary to heart-disease is large, tough, and extremely blood-gorged in its vascular zone, while the kidney, whose degeneration has evoked widespread complications and changes secondary to itself as events, although not in importance, will be found atrophic, pale, tough, and granular."

Traube's inferences were criticised by many writers, and with some skill by Bamberger in an article published in Virchow's "Archiv," Band xi., 1837, p. 12, who showed that valvular lesions of the heart (those remarkable fibrinous vegetation accretion forms), not only were no rarity in, but formed really a very common incident and complication of, the renal disease (as later experience has abundantly proved they especially occur in the large white kidney-disease of short course and excessive albuminuria); and that these valvular lesions, and not the kidney circulatory impediment, ought sometimes to be held guilty of the cardiac hypertrophy. He concedes, however, the main issue, Traube's real hit, that in some cases of chronic renal disease the heart was found greatly hypertrophied without valvular disease or any other obvious cause, and for this he was the first person to offer a mechanical explanation.

Meantime, the English observers and physicians were not idle, but having arrived at the conception of Bright's disease as a renal degeneration, presenting itself in several varieties with distinct pathologies, clinical symptoms, and issues, were directing their attention more to the best mode of distinguishing these separate forms during the patient's life, and at advancing diagnosis, prognosis, and treatment—*vide* Dr. Basham, "On Dropsy and its Connection with Disease of the Kidneys" (1st edition, 1858), and Dr. Dickenson: "Two essentially distinct conditions of kidney, giving rise to what is called Bright's disease" (*British Medical Journal*, 1859).

By both these writers good use was made of the microscope in investigating the sediment of the urine, as a clue to the changes taking place in the kidney, and in examining the kidney, in the hope that it might explain how its degeneration had been brought about.

It is an easy and an invidious task to look back now, and say how much of this labour was profitless; how few inferences made by Basham as to diagnosis upon the appearances of renal casts, have been confirmed; and how little light the earlier microscopical examinations of renal disease really threw upon the changes that took place in the tissues of the kidney, or upon the order in which they succeeded each other. The anatomy of the organ still was very imperfectly ascertained; and as with the lung, so with the kidney, to read the course of disease backwards to its beginning, from the appearances found at the death-stage, is to court failure and invite error.

Those who refer to Dr. Basham's work will see that, at this period, the estimate of the extent and gravity of renal degeneration, instead of being based, as the older writers—Christison and Gregory, and Osborne—had urged that it should be, upon the amount of urine passed, and on its density, as a measure of the functional capacity of the kidneys, ran grave risk of being hurriedly inferred from casts found in the sediment of the urine, which were valuable, no doubt, as additional evidence, but far from being all-sufficient in themselves to base an opinion upon.

Differentiation was the order of the day. The pendulum which Ferriehs had forced back to Bright's last-issued idea, that his disease was, essentially and pathologically, one interrupted by death, and thus encountered at different stages, was swaying, irresistibly swaying, in an opposite direction.

Beer, in his work on the connective tissue of the human kidney, published in 1859, was calling attention to two distinct forms of interstitial hyperplasia, which he had observed in renal disease: the one in circum-glomerular, the other intertubular. The circum-glomerular interstitial nephritis was, according to him, marked clinically by yellow-coloured urine, of low specific gravity, and presenting little urinary sediment; whereas, the intertubular commenced with hæmaturia, was attended by urine of high specific gravity, and possessing much sediment.

Traube writes in 1860 ("Klinische Untersuchungen," page 969), appealing that the name of Bright's disease should be given up, because it promulgated error, and led to the confusion together under one head of ever such a variety of forms of renal degeneration; the parenchymatous inflammation did not constitute it; this was a first change only, which might lead to it. Interstitial nephritis, or interstitial hyperplasia,

could be developed without any previous stage of parenchymatous swelling; and parenchymatous swelling was to be found in the renal changes secondary to old heart-affections.

Acts of Parliament and the Queen's pleasure apart, there are few things so difficult to shake yourself quit of as the name of a place, or of a man, or of a disease. While Traube was urging that the name of Bright's disease should be surrendered, because of its vagueness and uncertain applicability, Dr. Goodfellow, in some admirable lectures on "Diseases of the Kidney," published in 1861, was as strongly recommending its re-adoption in England in lieu of albuminuria for a varied but peculiar (specific) renal degeneration, which possessed certain well ascertained symptoms, and a moderately precise pathology of its own. He writes (p. 237): "It is from not separating the acute from the chronic stages, and from taking the mixed varieties as so many independent forms, that so much confusion has arisen."

Goodfellow was no blind believer in casts; he advised those who wished to make a sound diagnosis of the extent, and would forecast the issue of any case of renal disease, to go back to estimating the amount of urea excreted *per diem* by the patient; and directed attention to the grave secondary change undergone by the blood, when the normal elimination of urea was rendered defective, in consequence of any renal inadequacy.

Dr. Goodfellow's lectures showed considerable knowledge of foreign labours, as well as original ideas. In explanation of its peculiar coehetic colour, he argued (page 54), that the impurity of the blood in chronic renal disease might act, much as solutions of urea in laboratory experiments, in destroying the red blood-cells, and causing them to break up. At p. 217, he compiled a valuable table of measurements of the tubuli uriniferi, and of the small arteries of the kidney; and he was the first, at all events in this country, to recognise the important part played by the arteriols rectæ as channels whereby the blood could pass from the renal artery by a short cut into the renal veins, when the circulation by the lengthier route through the Malpighian bodies in the cortical substance, was obstructed by swelling of the tubules, or effusion of fibroserum into the intertubular lymphatics—a point which had been insisted upon by Professor Virchow in a very interesting pamphlet, published about 1860.

### ON TEMPERATURE AND ITS RELATION TO MORTALITY: AN ILLUSTRATION OF THE APPLICATION OF THE NUMERICAL METHOD TO THE DISCOVERY OF TRUTH.

By WILLIAM A. GUY, M.B., Cantab., F.R.S.,

One of the Honorary Presidents of the Statistical Society.

(Continued from page 283.)

DR. GUY, resuming the study of the table which he selected for examination, first distinguished the maxima from the minima in the several columns by close and open dots, and connected them by thin lines; thus converting it from a table of reference into what he terms a *Tentative Table*; and he learnt from it two facts, obviously meriting further investigation, namely, that after the fifth year of life, the highest mortality occurs uniformly, at all ages, in the first three months of the year, January, February, and March, and the lowest in the three months, June, July, and August, and that in six out of nine instances the lines and dots of maxima and minima ran parallel. Proceeding further with his inquiry by converting the table of reference into a table of discovery, by grouping the months into three sections of four each, Dr. Guy obtained results of singular interest, as adding a new fact to our knowledge of the relation of temperature to mortality. Heberden laid great stress upon the truth that cold is the most effective cause of a high death-rate. But he thought that it produced its deleterious effects chiefly on persons above 60, and in a less degree on the consumptive. He did not make such a use of his figures as to discover the two broad truths, 1. That the lowest mortality occurs at all ages in the summer, and with the exception of infants and children under five years, the highest in the winter; and 2. That with a solitary excep-

tion, the high mortality of the cold months increases, while, without exception, the low mortality of the summer months becomes less and less as age advances.

The high mortality of the colder months shows itself by a nearly unbroken increase, the low mortality of the warmer months falling lower and lower as men grow older.

Dr. Guy then showed, by the aid of figures, what the diseases are to which this high and low mortality are to be respectively attributed, so as to carry the inquiry beyond its present limits.

We know that cold weather is fatal to the aged, and we ascribe this their mortality to bronchitis as its leading cause. Perhaps we shall find that what is true of the bronchitis of old age is true in a less degree of the diseases of the lungs in the earlier periods of life, as well as of some diseases of other organs.

Heberden had already recognised the effect of cold in enhancing the mortality from consumption, but he did this without producing the figures that warranted his belief. Yet the materials for such a comparison are presented to us in his table for the three years 1797, 1798, and 1799, as well as the deaths from asthma. The aggregate figures for the three years, as obtained from the same source, are as follows:—

Cold months, 3,765; temperate months, 2,710; hot months, 2,189.

The facts relating to consumption and asthma and some other diseases, and groups of diseases were found to be as follows:—

1. *Consumption*.—Four cold months, 5,934; four temperate months, 4,834; four hot months, 4,016.

2. *Asthma*.—How fatally cold affects the asthmatic will appear from the following figures:—four cold months, 956; four temperate months, 468; four hot months, 263.

The mortality of the cold months exceeds that of the hot months to a very remarkable degree. While the death-rate by consumption in the cold months in no year amounts to double the rate of the hot months, in the case of the asthmatic it is more than twice as great in one year, nearly fourfold in a second, and close upon fivefold in a third. Nor is there any exception to the rule in any of the years comprised in the tables.

We see now why the lesser mortality of the hot season, already known to prevail among persons above 60, should extend through the whole of life for all ages without exception, and the greater mortality of the cold season, with the single exception of children under 2 years of age. Cold proves fatal in infancy and childhood mainly through the difficulty which must exist in maintaining a suitable temperature in union with a healthy atmosphere. Even in childhood the wasting maladies entered as consumption make themselves felt in the register of deaths, while the disease known as pulmonary consumption sweeps off a fifth or so of all who die between early youth and old age, and asthma and bronchitis complete the harvest of death among the aged.

3. *Dropsy*, or to speak more precisely, another precursor of death in the chief diseases of the internal viscera (heart, lungs, liver, and kidneys), which attack chiefly middle-aged and aged adults, is dropsy. The figures for dropsy are:—four cold months, 1,022; four temperate months, 873; four hot months, 735.

So that dropsy follows the rule of the better defined diseases which chiefly attack the adult. Cold is most, and heat least, fatal to those who suffer in this way, while the temperate months again occupy an intermediate position.

4. *Apoplexy, &c.*—There is a miscellaneous group of causes of death to be found in Heberden's tables, under the heading, "Apoplexy, palsy, suddenly," the facts being given for nine years (namely, the six years 1763-68, and the three years 1797-99). For this group also the winter season is the time of greatest mortality, and the summer season that of lowest mortality in seven years out of nine, and in the aggregate of the whole. But in one instance the mortality of the four temperate months exceeds that

of the winter season, and in one instance also falls short of the mortality of the summer season; but in both cases the difference is very small. If we convert the totals into percentages, we obtain 41 as the percentage for the cold season, 28 as that for the hot season, and 31 as that for the temperate season, which here again occupies an intermediate place.

The figures for this mixed group of apoplexy, palsy, suddenly, are as follows:—four cold months, 1,142; four temperate months, 860; four hot months, 780.

5. *Convulsions*.—These may be said to be to the disorders and diseases of infancy what dropsy is to the diseases of the adult. They are rather forerunners than causes of death. The figures for convulsions are:—four cold months, 4,330; four temperate months, 3,660; four hot month, 3,565.

The figures for the first and third of the three years, as well as the totals, follow the usual order. The four cold months are most fatal, the four hot months least fatal, the four temperate months intermediate. The totals reduced to a percentage yield for the three seasons in their order the numbers 37 per cent., 32 per cent., and 31 per cent., the cold months contrasting strongly both with the temperate and the hot months; but the difference between the last two being inconsiderable. In this convulsions differ from most other causes or precursors of death.

The influence of these five diseases or groups of diseases on the mortality of all ages proves predominant over other causes of death, of which some act directly as the temperature, and others follow an order of their own, that is to say, prove fatal neither in an inverse nor in a direct order.

The diseases returned in a bill of mortality as colic, flux, gripes, and looseness, belong to the category of those of which the fatality varies directly as the temperature, the hottest months being the most fatal, while the coldest are least destructive to life. The average figures for six years are as follows:—four coldest months, 136; four temperate months, 141; four hottest months, 156.

The figures for the several years offer great variety. Thus, in one year the cold months are credited with 6 deaths; in another with 42; the temperate months with 10 and 24; the hot months with 5 and 37.

But fever and small-pox both afford examples of diseases of the exceptional order, which do not vary directly or inversely with temperature; the deaths from fever being most numerous in the mixed temperate months of spring and autumn, the cold and the hot months following in order; while the largest mortality from small-pox occurs in the cold months, which are followed in their order by the hot and temperate months.

There is also a difference worthy of remark in the order of the seasons, or divisions, of the year in at least one of the group of zymotic diseases, according as the disease is epidemic or non-epidemic. It seemed reasonable to expect that measles would follow the inverse order of diseases aggravated by cold; and so it turns out to be in three non-epidemic years, when the figures stand thus:—

Four cold months, 77 deaths; four temperate months, 66; four hot months, 49.

While in a series of epidemic years there were no less than 139 deaths in each of the groups of temperate and hot months, made up of different numerical elements for the four months, and only 30 deaths for the four cold months.

But Dr. Guy here reminds the reader that he has been dealing hitherto with numerical returns which date as far back as the interval from 1732 to 1747, or with Heberden's tables, which begin with 1763 and end with 1799. (See his work from p. 8 to p. 27.) In referring to them he says he cannot withhold the expression of his surprise that numerical returns of a date so remote, and open to so many obvious objections, should have yielded to his method of treatment results, stamped, as it seems to him, with the characters of the highest probability, if not of positive

certainty. But be this as it may, it is but natural that he should seek to know whether more recent returns confirm or invalidate, as the case may be, the inferences drawn from those earlier documents. With this object in view, it was but natural to turn to the work of Dr. Scoresby-Jackson, to which reference was made at the beginning of the paper. Table C of his elaborate paper contains all the numerical elements required for an answer to Dr. Guy's inquiry.

The figures of that table show that what was true of the climate of London more than a century and a half ago was also true of the climate of Scotland a quarter of a century since, for the figures are taken from the reports of the Registrar-General for Scotland, as they relate to the eight largest Scotch towns, and are doubtless faithfully recorded. If we reduce the results to approximate percentages, we obtain the following figures:—Four cold months, 38 per cent.; four temperate months, 13 per cent.; four hot months, 29 per cent.; and there is not a single year of the six which forms an exception to the general rule. In each year and in the average of years the same order prevails. The mortality varies inversely as the temperature, though the figures, when reduced to percentages, exhibit inconsiderable fluctuations from year to year.

(To be continued.)

## OBSERVATIONS ON SKIN GRAFTING.

By CHARLES W. MCCARTHY, L.R.C.S.I.,  
L.K.Q.C.P.I., &c.

SINCE its introduction in 1869 by Reverdin, of Paris, skin grafting has been recognised by the profession at large as one of the most valuable additions of late years to our surgical art. This useful process is now in pretty general adoption in our hospitals, and, to some extent, in private practice, in the treatment of large granulating sores where completion of cicatrisation is retarded or impossible, owing to a too great area of granulating surface, and limited power of cicatrisation in the cuticular margin of the sore. I believe there is no operation which can be more successfully accomplished by minute attention to details; there certainly is none in which a little extra care and nicety in its performance will yield more satisfactory results,—a fact which, in my own practice, I have had ample opportunity of verifying.

Transplantation of skin is applicable to a variety of cases. Speaking generally, it is of value—

1. As the only means at our disposal of establishing cicatrisation in sores previously incurable owing to a too large area of granulating surface, or extreme skin tension, as over bony parts.

2. As a certain means of facilitating the completion of cicatrisation in any healthy granulating surface.

3. As a means of limiting undue contraction of cicatrices, and thus, in a special manner, contributing to obviate the unsightly deformities, that too often result from severe burns and scalds.

In large healthy ulcers it is invaluable to hasten cure; so also in the extensive sores that remain when the sloughs in anthrax have come away. In the latter cases I have had the very best results from it. I shall select from my notes two instances where I have been especially successful.

Mr. C., æt. 50, suffered in September, 1874, from a very large anthrax—the largest I have ever seen—engaging the occiput and nape of neck. When the sloughs separated an immense chasm was left, extending from ear to ear, presenting a frightful appearance. In the course of his illness the usual stimulating, tonic, and nutritive treatment was adopted. When the sloughs were removed I applied on lint, three times a day, carbolic oil (acid. carbolic  $\frac{3}{4}$ ss.; Ol. olive ad.  $\mathfrak{z}$ vij.) Under this local and constitutional treatment rich healthy granulations sprang up. Owing to the great extent of the sore, I deemed it

advisable to introduce skin grafts, with the twofold object of hastening cicatrization, and preventing subsequent disagreeable contraction of parts. The granulations were soon in a suitable condition for the reception of the grafts, *thirty-two* of which, at one operation, I carefully placed in position, the patient having freely allowed me to remove from the forearm seven or eight small pieces, which, by sub-division, made this number. Only trifling pain was experienced. On exposing the sore three days afterwards, I had the satisfaction of finding that *twenty-seven* had taken. It was most interesting to watch the stages of growth in these "centres of cutification." In a very few days islands and peninsulas of cuticle filled in the sore, and cicatrization was completed with magic rapidity, leaving perfect freedom of movement in the head and neck.

In a case of large anthrax occurring beside the spinal column—dorsal region—in an old gentleman, Mr. L., in April, 1878, I had equally good results, *twenty-five out of thirty* having grown at one operation, and the sore healing in a marvellously short space of time.

So large a number of grafts having been planted at one operation, the result in both these cases must be considered satisfactory, and was, no doubt, due as much to special care in placing and maintaining them in position, as to the suitable soil on which they were placed.

I believe the most favourable condition in granulations for the reception of skin grafts, is that in which they are ruddy, full, and ripe looking. To secure this, carbolic acid, in suitable combination, is invaluable, especially in anthrax, or, indeed, in most sores of the indolent class. As an antiseptic and stimulant it acts beneficially on the sore, and on the grafts themselves. In cases requiring much local stimulation, I have prescribed the following ointment with great advantage:—

R Vaseline } aa ℥j.  
Ung. resinæ }  
Acid. carbolic, ℥j.—℥ss.

Ft. ung.

When clarified, by submerging in another vessel containing hot water, it makes a very elegant preparation.

Given a case where skin grafting is desirable, the first and most essential condition to ensure success is a healthy state of the granulations. I have attempted the process in one or two instances where the granulations were not quite healthy, but cannot say I have been rewarded with even partial success. One was the case of an old lady with an irritable ulcer on the leg. Other methods of cure were previously tried without avail, so I determined to put on a few skin grafts. I placed half-a dozen in position, but was not satisfied that any of them grew. The ulcer, however, cicatrised soon after. Whether one or more of the grafts, unknown to me, may have carried on an abortive growth at the margin of the sore, and thus exerted a favourable influence, through contact or impression, producing healthy action and exciting cicatrization in the marginal cuticle, I am not prepared to say. I am persuaded by experience there is little use, if any, in transplanting skin on granulations not perfectly healthy. Suitable treatment, constitutional and local, to secure this important condition, will suggest itself in individual cases. Bearing in mind that *excessive* action in the process of repair is injurious, I believe the best results in skin grafting—all other things being favourable—are to be achieved in the maximum of local stimulation, at a point, in fact, when any further stimulation would be excessive. I find ruddy, ripe granulations on an even surface, discharging healthy pus—the most favourable conditions.

To procure grafts I generally select the anterior aspect of the forearm, where I find there is least pain, and usually proceed according to the directions given, so concisely, by Mr. Bryant, of Guy's Hospital, in his admirable work on surgery. Instead, however, of using the instrument he recommends, I catch directly and nip off, with an ordinary curved scissors, a small oblong piece of skin,

about a quarter of an inch long, taking care not to cut too deeply into the cutis vera, a very thin layer of which will suffice. If done dexterously, including only the cuticle with the *rete mucosum* and the mere apices of the papillæ, the pain is very trifling. There is no bleeding, and the patch heals without any treatment. On my thumb-nail, as recommended by Mr. Bryant, I divide this piece into about four parts, taking care not to bruise or otherwise injure the grafts. They usually curl up, and I catch each gently, by its outer surface, on the point of a tenaculum needle, to which it adheres almost without pressure, as if by attraction. The sore having been washed previously with carbolised water, I lay the raw side of the graft on a good ruddy granulation, to the convex surface of which it will immediately adhere, if *lightly* taken on the tenaculum. The curled graft at first does not lie evenly, but by a little gentle continuous pressure with the curve of the tenaculum, it quickly absorbs moisture from the granulation, loses its shrivelled appearance, unfolds itself, appears to get larger and fuller, and in a few seconds lies evenly on its new bed. Bleeding the granulations, as formerly practised, is not necessary. Indeed, I believe it rather tends to mar the success of the operation. The other grafts should be placed with similar care, one inch apart, according to Mr. Bryant. I generally, however, place them half an inch apart, and about the same distance from the margin of the sore, covering with successive rows of grafts the entire surface, unless it be exceptionally large, in which case I leave the centre free, as the grafts here will not take so readily. I believe it to be an advantage to place a sufficiently large number at one operation. It generally obviates the necessity for a repetition; and, if such can be avoided, it is better not to subject the patient a second time to even the trifling pain experienced. With due care it is quite as easy to get a large number to take as a few, especially if the grafts be placed in wide sores chiefly around the margin. The more numerous these "centres of cutification," the greater will be their effect in exciting cicatrization at the margin (a power which any ordinary observer must admit they undoubtedly possess), and the more quickly will they unite and cover in the sore by proliferation of their own cells. The grafts having been placed, it is of the utmost importance to keep them undisturbed *in situ*. I follow, with some modification, Mr. Bryant's plan, covering the sore carefully with a piece of fine gutta-percha tissue, previously rubbed with carbolic oil, placing over this a small pad of French wool to secure equal pressure, the whole being lightly strapped with adhesive plaster, and bandaged. On the third day I expose and wash the surface very carefully with tepid, carbolised water. Other methods, such as keeping the grafts *in situ* by means of threads strained across them, are not, perhaps, quite as practicable. Some surgeons object to the use of gutta-percha tissue, owing to its non-absorbent nature. It has done sufficiently well in my hands. Those who object to it might try very thin gauze, or, better still, some fine, white gossamer, lubricated with a weak solution of carbolic acid in oil, with or without glycerine, placing over it a light pad of that useful material known as "absorbent" cotton wool, and carefully, but not too lightly, strapping and bandaging.

Generally speaking, if the granulating surface be in a fit state to receive the skin grafts, if due attention be given to neatness and delicacy of manipulation, and the grafts be not subsequently disturbed from their position, there is no reason why each and every one of them should not grow. Failure is only to be ascribed to clumsiness or some neglect in the particulars mentioned.

A question naturally suggests itself. Why should not a large piece of skin be planted instead of several smaller pieces? The reasons are:—Firstly, it will not take with equal certainty because (a) it is difficult to remove a large piece without including in it too much of the cutis vera; this would be likely to militate against its growth. (b) It is difficult to keep its entire surface on intimate

apposition with the granulations; those parts not in apposition are prone to decay, and this decay is likely to spread to the entire graft. Secondly, even if it should take, no advantage would seem to be gained, for it remains, mushroom-like, on the cicatrix, in marked contrast to the tissues around, and growth from its edges is very limited.

Mr. Bryant questions whether newly-engrafted skin is not more liable than the old skin to undergo disintegrating changes. No doubt, for a limited period, it needs protection on exposed parts. Time, however, would seem to produce a hardening effect on the grafts and on the cicatricial tissue formed by them. This is fairly illustrated in the case of Mr. C. (above detailed), whom I specially visited yesterday (December 14th, 1880), *six years and some months* having elapsed since the pieces were engrafted in his neck. I found a slightly raised, movable cicatrix, flat, even, and healthy-looking, half-an-inch wide and six inches long, on which the site of most of the grafts was plainly visible, *twenty-two of which I counted*. The remaining five were not discernible. The grafts were mostly embedded in small depressions, but one or two appeared on a level with the surface, with a circular furrow around. None were above the surface. The cicatrix bore rough handling, which the patient himself exemplified. The individual grafts on being pricked with a needle proved to be highly sensitive. I questioned him as to any unusual tenderness in the cicatrix. He answered: "No, I have no tenderness whatever in it. I can use the comb as roughly here as on the crown of my head. Certainly, for a year after it occurred I had a sensitive feel in it, but nothing will affect it now." If anything were calculated to break down this engrafted tissue, the constant irritative effect of the comb would have done so.

The cicatricial tissue produced by grafts is apparently identical with that formed by the margin of the sore. The *rete mucosum*, or pigment layer, is evidently contained in it, as shown by the transplantation of grafts from a negro to a white man, the coloured area increasing largely around each graft—a fact which also proves growth from their edges by proliferation of their own cells. This growth, however, is at best but an imperfect copy of the grafts, which, even after so long an interval as above instanced, *retain their original size and colour, and appear distinct in character from the cicatricial tissue formed by them*. This has its drawback when we consider transplantation of skin as an aid to plastic operations on the face, where a neat result is looked for, though I have no doubt it is useful here in some degree. Doubtless, when the process was originated, surgeons were more sanguine as to its doing away effectually with scars, contractions, and deformities. At this happy result we have not yet arrived, nor are we, apparently, nearer its full attainment. It is certain, however, that very considerable advantages may be derived from skin grafting in suitable cases. From inquiries I have made, it does not seem to be as much employed by surgeons in provincial practice as it ought to be, considering its simplicity and usefulness. For my part, I have found it to work satisfactorily in private cases, where its employment was indicated; the patients feeling interested in this simple yet marvellous process, and gratified at its results.

Cloumel, March, 1881.

THE rates of mortality last week in the principal large towns of the United Kingdom per 1,000 of the population were—Leicester 13, Sheffield 17, Norwich 17, Bradford 18, Newcastle-on-Tyne 18, Edinburgh 18, Brighton 19, Birmingham 20, Leeds 20, Portsmouth 20, Sunderland 20, Salford 20, London 21, Wolverhampton 22, Plymouth 22, Glasgow 22, Nottingham 23, Liverpool 24, Hull 25, Bristol 26, Oldham 28, Manchester 28, and Dublin 30.

## Clinical Records.

### VICTORIA HOSPITAL FOR CHILDREN.

*Abscess in Thoracic Parietes simulating Epyema—Death—  
Post mortem.*

Under the care of Dr. JULIAN EVANS.

Reported by Mr. DAWSON WILLIAMS, M.B., Registrar.

WM. B., *æt.* 9, was admitted on February 9th, 1881. The family history was not good, one other child of the same parents had died of consumption, and the patient had always been a pale, delicate boy. He had scarlet fever in April last year, but made a good recovery; and appeared to be in fairly good health until about the middle of December last, when, without any obvious exciting cause, he began to complain of pain, referred to the region of the heart, and vomited. So far as was known he had received no injury. When admitted, he was seen to be a pale, fragile-looking boy, he lay habitually on his back, and appeared to be much prostrated. The left side of the chest moved less than the right, and measured a little less in circumference; the intercostal spaces at the left base were obliterated, and there was some superficial tenderness in the axilla; the side was absolutely dull on percussion as high as the third rib in front, and the angle of the scapula behind: above these levels the percussion note was tubular, and the breath sounds had a tubular quality; on passing downwards the breath sounds grew gradually fainter, and were scarcely audible at the posterior base. The percussion note over the right side was hyper-resonant, and the breath sounds were exaggerated. The cardiac impulse could be faintly felt in the usual situation, but at a maximum in the epigastrium a little to the right of the middle line. During the two days following admission the temperature ranged from 101 deg. to 98 deg.; respirations averaged about 30 in the minute, there was very little cough, but frequent profuse sweatings. On the evening of Feb. 11th a trocar was passed into the chest through the 7th space in the axilla, and about eighteen ounces of thick, brownish pus, with a very foul odour drawn off; under these circumstances it was thought best to lay the chest open freely, and introduce a drainage tube. The operation was followed by temporary relief of all the symptoms, and a fall of temperature to the normal. On the third day, however, the temperature ran up to 103 deg., with profuse sweatings, rapid breathing, and great distress.

On Feb. 15th a second opening was made in the 10th space, and a drainage tube passed through from the upper opening; on this day it was observed that a considerable area of the 8th rib, at the point where the tube entered the chest was bare and rough. As however, considering the condition of the child this did not seem an unlikely consequence of the previous operation, no importance was, unfortunately, attached to it. This second operation was followed by temporary improvement: but after four days the fluctuations of temperature and profuse sweatings again became marked, and were but little affected by the liberal exhibition of quinine. Without detailing the daily variations in the symptoms, it will be sufficient to say that, in spite of a stimulant line of treatment, combined with thorough cleansing of the suppurating cavity with antiseptic lotions, and most careful nursing, the patient's strength gradually ebbed away under the severe pyrexia, and frequent sweatings which he experienced, and he died on March 15th. The temperature for three days before death had been almost continuously above 102 deg.

The post-mortem examination revealed complete collapse of the left lung, which was universally adherent, so that the pleural cavity was entirely obliterated; the thickened parietal pleura was detached from the diaphragm, and from the side of the chest as high as the second rib, leaving a large cavity which had evidently

contained the pus withdrawn during life—in it was found about one ounce of purulent fluid, with shreds of yellow lymph. The upper margin and inner surface of the eighth rib, over an area of about half a square inch was rough and carious. On section the left lung was of a deep purple colour, breaking down easily under the finger: portions from every part sank in water. On the right side there were a few scattered pleural adhesions; the lung was emphysematous in patches, but not otherwise altered. The brain and other organs were examined, but showed no traces of tubercle or other pathological process.

*Remarks.*—As will be seen from the account of the physical signs (transcribed from notes taken at the time), the case presented all the signs commonly associated with empyema, and the operation proved that there was pus within the chest. The interest of the case seems to be the unusual source of this effusion, for looking at the facts, there can be little doubt that the suppuration really proceeded from the carious rib, since the pleural cavity was entirely obliterated: had this fact been recognised during life it would probably have been advisable to have excised the diseased portion of rib—an operation which would probably have been attended by no inconvenience, for the excision of a portion of one or more ribs for empyema is an operation which has been attended by the most favourable results in the hands of Peitavy, in Germany, and Mr. Thomas, in Birmingham (*Birmingham Med. Rev.*, 1880). It is doubtful, however, whether in this particular case anything could have obviated the fatal result, owing to the prostrate and exhausted condition of the patient. The facts of the case may, however, make surgeons more alive to a possible source of purulent collections simulating empyema.

## Transactions of Societies.

CLINICAL SOCIETY OF LONDON.

FRIDAY, APRIL 8TH.

T. SMITH, F.R.C.S., Vice-President, in the Chair.

Dr. BERNARD O'CONNOR on a

CASE OF "SYPHILITIC PSORIASIS OF FACE AND NECK."  
(Patient exhibited 11th March, 1881.)

Patient first came under observation 2nd March, 1881. Aged 28 years. Always healthy up to six months ago, when complaint was made of pains in the head, most severe in the temples. For this she went under treatment. A week subsequently there was sore throat; a fortnight later still, an eruption appeared all over her, that on the face being similar to what we now see, while that on the body and limbs took the form of "dark bluish spots." She remained under treatment for six weeks. The patient's husband had, with the exception of the remarkable eruption on the face, presented the same symptoms, though a little earlier; he had also had a severe iritis. He never had a chancre. Has two healthy children; never lost any; has had neither abortion nor a miscarriage. Is quite regular. Mother died at 34 of some "liver disease." Father and all other members of the family quite healthy. On examination I found a number of pinkish-white scaly rings and some darker circles all over the face, including eyelids, and on front, sides and back of neck; also some half-circles. All stages of development were noted at the same time. Skin between is healthy. The rings, which spread by three outer margins, are not quite symmetrical. Rings incomplete at point of contact. The skin is naturally fair. Eruption always dry and itches most at margins. No trace of it on elbows, knees, palms, soles, nose, lip, mucous membranes, ears, or scalp; but the hair has been shed in large quantities, and there is dry seborrhoea. Few brownish maculae on body, backs of thighs, and inner sides of arms, evidently resulting from syphilitic roseola. Excavated ulcer near right tonsil. No affection of nails. Scaly eruption on shins somewhat resembling, though really different from,

squamous eczema and ordinary psoriasis. Eruption on face might, in some respects, be compared to that of lichen rubra and *Herpes Circinatus*. Under the microscope, with a power of 450 diameters, were found slight hyperemia and infiltration of rete mucosum. Reasons for classifying this case as *sypilitic psoriasis*:—1. History of patient and husband, and absence of any history of psoriasis (or, in fact, of any skin disease) in any member of her family. 2. Dry scales less in amount and darker in colour than those found in ordinary psoriasis. 3. Absence of eruption from elbows and knees. The non-appearance of any affection of the palms of the hands and of the sides of the feet is unusual in syphilitic psoriasis. *Treatment.*—Hydrarg. perchlor. (gr. 1-12), c. tinct. chinchonæ, t. die, and topical application of ungtm. hydrarg. nitratæ.

Mr. RUSHTON PARKER on a

CASE OF ARTERIAL HEMATOMA OF THE FOREARM DUE (APPARENTLY) TO EMBOLIC ARTERITIS AND PERFORATION.

William Griffin, æt. 14, had rheumatic fever in the first quarter of 1879, during which he experienced pain in the right forearm, followed by swelling of the whole limb, eventual subsidence in the arm, but gradual increase in the forearm. He was admitted into the Liverpool Royal Infirmary on 23rd July, 1879, and was found to have an oval swelling of the right forearm, tense, but slightly elastic, without pulsation, the previous existence of which the patient distinctly negated. Incision under ether revealed a blood tumour between the bones and deepest muscles on the flexor side, and an open artery with upper and lower aperture. This vessel was tied, and the wound treated by the cartilage method without the spray. Inflammation, however, became intensified, and septic conditions arose, without, however, any evil result until after the 20th, between which and the 30th several attacks of secondary hæmorrhage occurred. The wound was eventually searched for a bleeding point, but none found, the cozing being general. Ergotine subcutaneously, and turpentine locally, with elevation of the limb were followed by cessation of bleeding and rapid cicatrisation. Hitherto no cardiac or respiratory symptoms had been present, though a systolic and diastolic murmur revealed aortic obstruction and regurgitation both on admission and since. He now, after the sixth week, had severe dyspnoea, with palpitation and cardiac pain, commencing with an attack of epistaxis, and producing cyanosis. Opium and digitalis were given, and in a fortnight he was better, with occasional remissions. Under a regulated diet of bread, butter, potatoes, tea, and beef-tea, excluding especially milk and flesh, with opium and no digitalis, he gradually made a complete recovery from all impairment of the respiratory and circulatory functions. The murmurs, however, remained for months, but he was lately (February, 1881) totally free from murmur, and in robust health and strength. Partial division of the median nerve in the final operation, has resulted in impairment of the palmar muscles concerned, but the main use of the hand is good, and all the most important movements preserved. *Remarks.*—The appearance of septic influences is of course due to causes which were probably preventible; and the secondary hæmorrhage was almost certainly due to the intensified inflammation which ensued. This case is only one among examples, which to many surgeons are well known, proving in the clearest way the influence of inflammatory irritation in promoting hæmorrhage from vessels in the vicinity. The converse, though not demonstrable here, is experienced in other cases where the removal of irritation (such as the distensible force of retained discharge or blood-clot) is followed immediately by cessation of bleeding which may previously have been profuse, and apparently unquenchable. As to the original blood-clot, the hæmorrhage of which it was the substance, resulted evidently from perforation of the artery concerned. The blocking of this artery and the consequent collateral flexion are circumstantially evidenced in the history, while the conditions requisite for embolism were, to say the least, rendered possible by the clinical signs. The age of the patient and all the circumstances leave, it is thought, no choice outside the supposition that an embolism, consisting of active inflammatory material, on becoming impacted in the anterior interosseous artery of the forearm led to acute arterial inflammation and consequent perforation in place of the obliteration more commonly to be expected.

Mr. T. SMITH said these cases were very rarely met with. He thought the explanation offered a probable one. Rupture frequently ensued from cerebral embolism, but occurs in limbs only very infrequently.

Mr. GODLEE inquired if any arterial disease had been noticed in any other part of the patient's body?

Mr. HEATH remarked that it was unusual to find arteries diseased at so early an age, and for this if for no other reason Mr. Parker's case was unique. He did not, however, feel quite satisfied with the explanation of it that had been given. Had careful inquiry been made to ascertain whether an accident might have produced the arterial wound? He thought the boy might have done better had the wound been closed with lint and a compress applied over it.

Mr. M. BAKER inquired when the boy had last been seen, and what his condition then was? Curious cysts, he said, sometimes occur and simulate the appearances due to embolism, but only a thin layer of blood is found surrounding them.

Dr. COUPLAND wished to know if embolism had been found in any other part of the body. He commented on the remarkable fact that the boy had lost the signs of valvular disease of the heart apparent during his early treatment.

Mr. RUSHTON PARKER replied that the age of his patient (14 years) excluded the idea of aneurism. The two openings in the artery were well defined. The back of the vessel was plainly visible. In explaining the condition, he imagined an embolism might have lodged in the artery and caused the mischief. He had been unable to gather any history of a traumatic origin for it, and examination by the aspirator proved it to be non-malignant. The record of the case, moreover, suggested embolism. There had been pain and swelling of the whole arm, which gradually diminished. The clot found was firm and black, and formed under considerable pressure. The heart was in a bad state on admission; its improvement was very marked.

Mr. HEATH asked if the artery had been divided?

Mr. PARKER said it had not; and there had been no evidence of other embolisms, or of any other disease.

Dr. STEVENSON on a case of

#### MENINGOCELE.

A female child, the last of a family of thirteen, was brought to the Children's Hospital when three weeks of age with a cleft in the cranial and facial bones extending from the posterior fontanelle to the alveolar process of the jaw. Between the widely-separated eyes and nostrils there was a tubercular swelling communicating freely with the cranial cavity. There was no cleft palate. Respiration was peculiar, a few short, quick inspirations being succeeded by a pause. The heart's action was accelerated. The mother stated that when she was three months pregnant she was much frightened by seeing the body of her son in a hospital mortuary, and to this fright she attributed the infant's deformity. The child lived to the age of 4½ months, and a post-mortem examination was refused. Out of 39 cases recorded by Laurence, 21 were males and 18 females. In 53 out of 79 cases the meningocele was occipital; in 6 instances adult life was attained; the majority dying in early life.

Mr. T. SMITH said he had never seen a child so horribly deformed as the subject of Dr. Stevenson's paper. The major part of the brain was in the region of the nose, and the eyes were widely separated. It was remarkable that life had been prolonged to four months. The mother had told him that besides merely seeing her son in the dead-house she felt his head, and had been shocked to find his skull-cap removed, and a soft yielding vacuity where it should be. This produced a strong mental impression to which the congenital defect of her child might be due.

Mr. JOHN H. MORGAN on a

#### CASE OF PROGRESSIVE PAINFUL INFLAMMATION OF ARTERIES.

G. W., æt. 46, contracted syphilis at eighteen; has since married, and has several healthy children. He is subject to a curious congenital enlargement of superficial veins of chest and abdomen. Nine years ago was a patient at Guy's Hospital, under Dr. Willis, who has described his case. In 1876 suffered pain in left armpit, which passed down to bend of elbow, and then left him. In 1877 came under Mr. Morgan's care suffering from pain in the left arm, for which there seemed no evident cause. There was no swelling, and he soon recovered from this attack. In 1880 an attack of

sudden and severe pain in the right groin, deep-seated, and made intense when the part was pressed. The area of pain was confined to two to three inches in the course of the femoral artery, and to one to two inches on either side of it. This pain gradually travelled down in the course of artery to the popliteal space, being traceable throughout, and being more severe at the part corresponding with the opening in the adductor magnus. In course of time the pain passed into leg, and here some limited œdema was seen at the seat of pain, but not beyond. Similar pain came suddenly in the right axilla, and passed gradually down in the course of the brachial artery into the forearm, and here again a limited œdema occurred. He was treated with iodide of potash, alkalies, and biniodide of mercury at various times, and in varying quantities, but without material effect upon the disease. Subsequently the right carotid artery was affected in a similar way; the symptoms varied evidently to disease of an artery, probably inflammation of the fibrous coat, since the pain passed from the centre to the periphery, was in the course of the various arteries, and was made intense directly the finger perceived the pulsation of the artery beneath it. I have not been able to find any record of observation of similar symptoms. The patient is now in good health, and has had no recurrence of the symptoms. He was shown to the Society.

Mr. HEATH said the case was peculiarly interesting from the fact that none of the arteries were blocked, as usually occurs in arteritis. The condition of the vessels might possibly be consequent on inherited diathesis, tending to weaken their walls, e.g., gouty, &c.

Mr. McHARDY described a disproportion he had observed with Dr. Buzzard, between the retinal vessels of the patient, the arteries being only one-third the size of the veins. This was due to the diminution in the size of the arteries; the coats were not thickened, but the whole vessels were indistinct, exhibiting a double contour.

Dr. F. TAYLOR thought it would be interesting to know the present condition of the arterial walls.

Mr. HAWARD considered that, the patient having suffered from syphilis, this fact afforded the most probable explanation of the disease. Intermission in such cases is a common experience, and in the one described its occurrence favoured the view that it was an instance of syphilitic arteritis. In connection with Mr. Heath's remarks on the absence of clots from the vessels, the question arose whether arteritis is recognisable at all during life, and whether clots did form in the living vessels.

Mr. HEATH explained that arteritis is not common in clinical experience. Books describe the arteries as obstructed in it, but its occurrence is most rare. He, himself, had no personal experience of the disease, and quite believed the ordinary book views of it might require to be modified.

Mr. HAWARD continued that in an extensive series of post-mortem examinations, he had never found clots in arteries, though often he had discovered evidences of inflammation in the walls of those vessels. Of course, those cases in which a plug had been lodged in the vessel, and then, acting as a foreign body, excited inflammation around it, were excepted.

Mr. T. SMITH thought the diagnosis of this case during life had been unique. He would like to know more definitely what led to it. He, himself, had never seen arteritis during life. In those instances where, in cases under his care, arterial obstruction occurred, it was due to excessive thickening of the walls.

Mr. R. W. PARKER asked on what grounds neuritis was excluded in the diagnosis?

Mr. RUSHTON PARKER said, in some instances, arteritis produces clots by plugging. Mr. Lister, twenty years ago, recorded an instance of clotting in the artery of a child. Traumatic arteritis produced arterial clotting. In two instances he had witnessed plugging produced by acute arteritis in a wound. In one case the brachial, in the other, the subclavian artery, was plugged by blood-clot after the injury.

Mr. MORGAN said gout was excluded by the patient's family history. He was aware of the frequency with which arteritis is accompanied by plugging, but at no time could he find in his patient any difference in the volume of blood in the diseased vessels. He would be glad to add the facts described by Mr. McHardy to his paper. No sphygmographic tracings of the pulse had been taken. Neuritis was not at any time indicated as the cause of disease, this never having

been of nervous origin. The diagnosis was not made till some time after the first observation of the case.

#### NEVOID ENLARGEMENT.

Mr. T. SMITH showed at the end of the meeting, a child in whom one leg was the site of extensive nevoid enlargement, unique in character. Mr. Smith described three somewhat similar cases. One he had treated by bandaging, which induced a red and painful state of the limb, followed by weakness, and death. The skin and subcutaneous tissues were much hypertrophied, and the cellular tissue of the pelvis was invaded by the nevoid growth. A second case was that of a young lady, in good circumstances; the hypertrophy of the limb was very great, but she improved under the better home treatment she enjoyed than is usual in the more dependent classes of society. In the case exhibited, bandaging had been first attempted, but the child's rapidly deteriorating health recalled the experiences formerly gathered under similar circumstances, and an elastic-stocking had replaced the bandage, with marked benefit to the patient.

## Special.

### ARMY, NAVY, AND INDIAN MEDICAL ITEMS.

**FEVER IN MADRAS.**—The following particulars occur in an interesting paper by Surgeon C. Sibthorpe, I.M.D., which appeared in the *Indian Medical Gazette* for March:—Typhus fever is never seen in Madras, although there is a very great over-crowding in some of the native bazaars, and their houses are hardly ventilated. Enteric fever—that is, a continued fever characterised by the presence of rose-coloured spots, chiefly on the abdomen, and a tendency to diarrhoea, with specific lesion of the bowels—exists in Madras, and has done so for many years; in fact, as far back as 1838 the records of the civil hospital show such cases, but until the year 1878, judging by the mortality statistics, this fever has never appeared in a fatal form, and since then the admissions have again become rare, though the sanitary state of Madras has not much improved since 1878, and there is now as much decomposing matter in the bazaar as there was then. The differential diagnosis between this disease and tubercular meningitis, acute phthisis, and tubercular peritonitis, presents the same difficulties as it does in cold climates; but here we have the question before us whether the case is one of malarial remittent, simple continued, enteric fever, or a mixed variety of the first and last, and the diagnosis is by no means easy. Mr. Sibthorpe does not think that the temperature range is of much help; in fevers it may vary much. Relapsing fever does not occur in Madras. During the late famine no case of that disease came under notice. Malarial fevers are also of rare occurrence in the Presidency town, the greater number of cases observed originate further inland.

**THE ARMY MEDICAL SERVICE.**—Sir William Muir, so the *United Service Gazette* states, is now commencing his eighth year as Director-General of the Army Medical Department, which requires a deal of nursing after its recent changes. It is difficult, however, to see why Sir William should be retained as nurse when his proper successor was at hand, and the promotion could have gone in the usual way. An attempt may be made to perpetrate a job, but it will be a job which is certain to meet with a scathing exposure.

**ARMY HOSPITAL CORPS.**—An Army Hospital Native Corps for service with British troops has been established in India, the head-quarters being at the office of the Surgeon-General of Her Majesty's Forces, who is charged with the command and administration. The corps comprises such men of the previously existing hospital establishment as may be qualified by age and character, and additional recruits are to be appointed as required. All men joining the corps will be duly enlisted and attested as "hospital attendants." The corps will consist of the following classes, viz., ward servants, cooks, water carriers, and sweepers. For the present the total strength of the corps will consist of 1,872.

### NEW REGULATIONS FOR THE NAVAL MEDICAL SERVICE.—

A report circulates that candidates for the Medical Department of the Royal Navy are no longer to be sent to Netley, but that as heretofore they are to undergo their course of probation at Haslar. It is also stated that passed candidates for the Indian Service will for the future undergo their probationary course elsewhere than at the Royal Victoria Hospital, probably at the several Presidency hospitals in India. This is in accordance with reason, for surely Indian diseases are best studied in India.

**MILITARY PUNISHMENTS.**—According to the draft rules on summary punishments in the army recently promulgated by the War Office, they may consist of "any one or more of the following, namely:—(a) Putting the offender in irons. (b) Attaching him, while on the line of march, to a cart, waggon, or horse, so as to compel him to move onward at a walking pace. While so attached he may be handcuffed or otherwise secured, so as to prevent his escaping, but he must not be in fetters. (c) Requiring the offender to carry extra burdens or weights not calculated to injure his health." Then follow a number of particulars in reference to the manner in which these punishments are to be carried out, the whole concluding with this admonition: "Officers will take care that the above punishments are inflicted in such a manner as is not calculated to cause injury or to leave any permanent mark on the offender, and the punishment shall always be stopped or mitigated on the representation of the responsible medical officer that the continuance of the punishment will be prejudicial to the offender's health." Now, with regard to these matters there appears to be this difficulty, that if a soldier declines to carry weights or to be dragged along at a cart tail, how can he be forced to do so. Men under such circumstances have been known simply to throw themselves down and absolutely refuse to be so dragged; nor can any medical officer declare that "the pains" in the joints, "the rheumatism," the "oppression at the heart," and so on, which they may assign as a cause of their inability is not real. If, on the other hand, an undetected aortic aneurism should give way while a man is being dragged, what would be the result to the medical officer concerned? And yet there are cases in which its detection may be simply impossible.

### THE NAVAL MEDICAL WARRANT.

THE *London Gazette* of Tuesday, April 5th, 1881, contains the following:—At the Court at Windsor, the 1st day of April, 1881. Present, the Queen's Most Excellent Majesty in Council.

Whereas there was this day read at the Board a Memorial from the Right Honourable the Lords Commissioners of the Admiralty, dated the 30th of March, 1881, in the words following, viz.:—

"Whereas we have had under our consideration the Regulations governing the position of Medical Officers of your Majesty's Navy, and whereas we are of opinion that it is desirable to effect certain modifications and improvements therein with a view of placing such officers in the position we think it advisable should be granted to them, we would humbly submit for your Majesty's approval the following regulations for the remuneration, position, advancement, and retirement of the aforesaid officers, and we would submit that such regulations should take effect from 1st April, 1881, and be applicable only to officers on the Active List of the Royal Navy at that date, except that as regards surgeons entered since 1st January, 1881, we would submit such regulations be in force from the date of entry.

"**Numbers.**—1. The Active List of Medical Officers not to exceed—Inspectors and Deputy Inspectors-General of Hospitals and Fleets, 16 (of whom not more than four to be Inspectors-General). Fleet Surgeons, Staff Surgeons, and Surgeons, 400.

"**Promotion.**—2. An Inspector-General of Hospitals and Fleets to be selected from amongst deputy inspectors-general who have in that rank three years' foreign service; or four years' mixed service, of which not less than two to be abroad, or five years' home service in such appointments as produce foreign service, and provided that they have not refused to go abroad if called upon.

"3. A Deputy Inspector-General of Hospitals and Fleets to be selected for ability and merit from amongst fleet surgeons.

"4. (a) The rank of Fleet Surgeon to be granted to Staff Surgeons on completion of twenty years' full-pay service, if recommended for advancement by the Medical Director-General, subject to our approval. (b) Power to be given to us to make, at our discretion, special promotions from the rank of Staff Surgeon to that of Fleet Surgeon in cases of distinguished service or conspicuous professional merit, such promotions to be exceptional, and not to exceed the rate of one in any two years. The total number at any one time of Fleet Surgeons holding that rank by such special promotions not to exceed six. (c) Officers who have been specially promoted to the rank of Staff Surgeon for distinguished service or conspicuous professional merit, to be eligible for promotion, if recommended by the Medical Director-General, to the rank of Fleet Surgeon after eight years' full-pay service as Staff Surgeon.

"5. (a) Rank as Staff Surgeon to be granted, subject to our approval, to surgeons at the expiration of twelve years from the date of entry, provided they are recommended by the Medical Director-General, and have passed such examination as may be required after completion of eight years from date of entry in the rank of Surgeon. (b) Power to be given to us to make, at our discretion, special promotions to the rank of Staff Surgeon, in cases of distinguished service, or conspicuous professional merit, such advancements to be exceptional, and not to exceed the rate of one a year. No officer to be so promoted unless he passes the examination prescribed for other Surgeons, but in such a case the requirement of eight years' service to be dispensed with. The total number at any one time of Staff Surgeons holding that rank by such special promotions not to exceed eight.

"Relative Rank.—6. Existing regulations to remain in force with the following exception—viz: In all matters wherein the Army and Navy Administration are concerned, Fleet Surgeons to rank with and as Brigade Surgeons.

"Full Pay and Allowances.—7. The undermentioned scale of full pay to be substituted for that now in force:—

Rank.	Daily.	Yearly.
	£ s. d.	£ s. d.
Surgeon—		
On entry .. .. .	0 11 6	209 17 6
After 4 years' full-pay service ..	0 13 6	246 7 6
8 " " " " " "	0 15 6	282 17 6
Staff Surgeon—		
On promotion .. .. .	1 1 0	388 5 0
After 4 years' full-pay service in rank ..	1 4 0	488 0 0

Deputy Inspector-General .. .. .	2 2 0	768 10 6
Inspector-General .. .. .	2 15 0	1003 15 0

"8. The allowance of 5s. a day in addition to full pay at present granted to the Fleet Surgeon of a flagship bearing the flag of a Commander-in-Chief on a foreign station to be given to the senior medical officer of such ship, whether a fleet or staff surgeon, and an allowance of 2s. 6d. a day to the senior medical officer (being a fleet or staff surgeon) of the ship of a commodore or of a senior officer commanding a foreign station. Allowances to be granted as follows to officers giving the course of instruction to surgeons on first appointment to the Naval Service:—To a medical officer of Haslar Hospital, conducting the course, £150 a year. To a junior medical officer of the same hospital, assisting him, £50 a year. No other alterations to be made in the allowances of medical officers.

"Half-pay.—9. The undermentioned scale of half-pay to be substituted for that now in force.

Rank.	Daily.	Yearly.
	£ s. d.	£ s. d.
Surgeon—		
Under 3 years' full-pay service ..	0 6 0	109 10 0
After 2 " " " " " "	0 7 0	127 15 0
" 4 " " " " " "	0 8 0	146 0 0

" 6 " " " " " "	1 0 0	365 0 0
Deputy Inspector-General—		
On promotion .. .. .	1 5 0	456 5 0
After 3 years' full-pay service in rank ..	1 7 0	492 15 0
" 4 " " " " " "	1 9 0	529 5 0
Inspector-General .. .. .	1 18 0	663 10 0

"Retirement.—10. Compulsory retirement to be as follows:

Inspector and Deputy Inspector - General of Hospitals and Fleets .....	At the age of 60, or at any age if he has not served for 5 years.	To be retired irrespective of age if found physically unfit for service.
Fleet Surgeon, Staff Surgeon, and Surgeon .....	At the age of 55, or at any age if he has not served for 5 years.	

"11. Voluntary retirement and withdrawal to be allowed as follows:—(a) Every officer to have the option, subject to our approval, of retiring after twenty years' full-pay service on the scale of retired pay, provided in paragraph 12, or on the scale of gratuities provided in that paragraph, if he is not eligible for retired pay. (b) At the expiration of eight, twelve, or sixteen years' full-pay service every officer to be permitted, subject to our approval, to withdraw from the Naval Service, receiving a gratuity on the scale laid down in paragraph 12. The name of an officer so withdrawing will be removed from the lists of the Navy, with which all connection will then be severed. (c) Voluntary retirement and withdrawal to be allowed, as a rule, only when an officer is unemployed or serving at home.

"12. Gratuities and retired pay on the undermentioned scale to be granted on retirement and withdrawal:—

Surgeons and Staff-Surgeons—	Gratuities.		Daily.		Yearly.	
	£	s. d.	£	s. d.	£	s. d.
After 8 years' full-pay service	1000	0 0				
" 12 " " "	1500	0 0				
" 16 " " "	2250	0 0				
Fleet Surgeons—						
After 20 years' service .. .. .			*1 0 0	..	365 0 0	
" 24 " " " " " "			*1 2 6	..	410 12 6	
" 27 " " " " " "			*1 5 0	..	455 5 0	
" 30 " " " " " "			*1 10 0	..	512 10 0	
Deputy Inspector-General .. .. .			1 15 0	..	638 15 0	
Inspector-General .. .. .			2 0 0	..	780 0 0	

\* To obtain this rate an officer must hold the Commission of Fleet Surgeon.

† Or on compulsory retirement at the age of fifty-five.

"13. An officer retired with less than twenty years' service, on account of disability contracted in, and attributable to the service, to receive the half-pay of his rank, or with our consent, a gratuity on the scales given in paragraphs 12 and 14 (b).

"14. An officer retired with less than twenty years' service, on account of disability contracted in, but not attributable to the service, to receive—(a) If he has over eight years' full-pay service, either a gratuity on the scale given in paragraph 12, or half-pay, according as we think fit. (b) If he has less than eight years' full-pay service, such gratuity as we may think fit, not to exceed the rate of £125 for each year of full-pay service.

"15. Under circumstances other than those specified in paragraphs 13 and 14, an officer retired with less than twenty years' service to receive a gratuity, on the scale laid down in paragraph 12, if he has eight years' full-pay service, and on that provided in paragraph 14 (b) should his full-pay service not amount to eight years. Half-pay or retired pay not to be allowed—except that every officer on the Active List on 1st January, 1881, if compulsorily retired, shall be allowed, at his option, to receive half-pay, but subject to the provisions of Orders in Council for reduction of half-pay and retired pay.

"16. The power vested in us of granting reduced rates of half-pay and retired pay in cases of misconduct, to be extended to the award of gratuities on retirement, and the gratuity awarded in such case to be reduced to such amount as we think fit.

"17. An officer retiring after 20 years' full-pay service to be eligible if recommended by the Medical Director-General for special reasons on account of distinguished or meritorious service, for a step of honorary rank, such step to be awarded at our discretion, and not to confer any claim to increase of retired pay or widow's pension.

"18. All retired Officers to be liable till the age of fifty-five, to be called upon to serve in time of declared national emergency in a rank not lower than that held on retirement. This liability not to exist in cases of withdrawal on the conditions specified in paragraph 11 (b).

"Definition of Service.—19. Service to reckon as follows:—(a) When borne on the books of any of your Majesty's ships or vessels, or when employed in Naval Hospitals or other Civil establishments at or under the Admiralty to be full-pay service for all purposes, but subject to the provisions in paragraph 2 as regards promotion. (b) Service under any other department which may be declared by us, with the consent of the Lords Commissioners of your Majesty's Treasury, to be for this purpose Naval Service, and Service on Commissions or

Committees on Naval matters of importance to be full-pay service for such purposes, and to the extent to which it has hitherto reckoned as service under the provisions of Art. 216 of the Regulations of 1879, and those of Orders in Council of 22nd February, 1870, 18th May, 1870. (c) Time on half-pay to count as one-third service for increase of retired pay, but not for any other purpose.

"*Widows' Pensions.*—20. Where an officer retires or withdraws on a gratuity, his widow and children to have no claim to pension or compassionate allowance. 21. The undermentioned articles of the regulations and provisions of Orders in Council to be cancelled except as regards officers retired before 1st April, 1881. Queen's regulations and Admiralty instructions 1879. Articles 215 as regards medical officers; 219 the whole; 241 paragraphs *a* to *d* inclusive. 265, the whole. Appendices XX. and XXIII., as far as relates to full-pay and half-pay of medical officers. Order in Council 22nd February, 1870. Section V. the whole. Section VIII. the whole as far as relates to medical officers. Section IX. the whole as far as relates to medical officers. Section X. the scale of retired pay, and paragraphs 2 and 3, as far as medical officers are concerned. Section XII. as regards medical officers. Order in Council 4th February, 1875, the whole. We would represent to your Majesty that the Lords Commissioners of your Majesty's Treasury have assented to the above proposals."

Her Majesty having taken the said Memorial into consideration, was pleased by and with the advice of Her Privy Council, to approve of what is therein proposed. And the Right Honourable the Lords Commissioners of the Admiralty are to give the necessary directions herein accordingly.

C. L. PEEL.

## The Mineral Waters of Europe.

### THE "MEDICAL PRESS" ANALYTICAL REPORTS ON THE PRINCIPAL BOTTLED WATERS.

By CHARLES C. R. TICHBORNE, LL.D., F.C.S., F.I.C.,  
President of the Pharmaceutical Society of Ireland, &c.

WITH

### NOTES ON THEIR THERAPEUTICAL USES.

By PROSSER JAMES, M.D., M.R.C.P.Lond.,

Lecturer on Materia Medica and Therapeutics at the London Hospital, Physician to the Hospital for Diseases of the Throat, &c.

(Continued from page 295.)

#### Vals.

THE Vals waters are also very well known alkaline springs in Ardèche, France. Like the Vichy waters they are bottled under government supervision, but the system adopted is not so good, the year of bottling not being marked upon the capsules as in the last-named waters. This point is of some considerable importance as the waters are inclined to deposit. The bottle therefore, should be held up to the light, and if it contains any appreciable amount of deposit it should be rejected. There are a great number of springs at Vals, but it will be sufficient to give the composition of a few.

The most important springs are—

*Magdeleine* (S).—Very rich in carbonate of sodium, contains about 350 grains per gallon.

*Saint-Jean* (S).—Very little mineralised, only containing 175 of total solids per gallon.

*Dominique* (M).—Similar, but said to contain arsenic and iron in considerable quantities.

*Précieuse* (S).—Is stated to be the most gaseous. It is the least alkaline of the strong alkaline waters.

*Desirée* (S).—Similar to the previous one.

*Rigolette* (W).—Given as containing no magnesia.

It will thus be seen that the Vals waters vary considerably, and that if they were prescribed indiscriminately as "Vals waters," the patient would find a marked difference if, after taking St. Jean (175 grains), he accidentally changed it for Magdeleine (350 grains).

The Vals springs are all highly carbonated, and it is probable that they are more suited to consumption at the source than for importation. M. Candelle in his "*Manuel de Médecine Thermale*" divides the Vals into strong, medium, and weak, according to the quantity of bicarbonate of sodium that they contain. We have, according to his classification, put "S," "M," and "W" against those waters which we have named, but do not wish it to be inferred that we adopt this classification.

We now subjoin our analyses of four selected Vals waters—

<i>Précieuse.</i>			
Bicarbonate of sodium ... ..	...	...	180·32
Bicarbonate of potassium ... ..	...	...	7·02
Carbonate of calcium ... ..	...	...	11·72
Carbonate of magnesium ... ..	...	...	13·06
Carbonate of protoxide of iron ... ..	...	...	0·34
Chloride of sodium ... ..	...	...	1·90
Chloride of potassium ... ..	...	...	0·52
Sulphate of soda ... ..	...	...	6·01
Sulphate of calcium ... ..	...	...	5·60
Alumina ... ..	...	...	2·03
Lithium, trace			
Organic matter, trace			

Total solids ... .. 228·52

Free carbonic acid not determined

*Skeleton analysis of Half-a-pint (10 fluid ounces).*

Solids.	Antacids.	Salines.	Purgatives.
14·28 gra.	13·27 gra.	·15 gra.	·37½ gra.

#### *Desirée.*

Bicarbonate of sodium ... ..	...	...	165·01
Bicarbonate of potassium ... ..	...	...	7·12
Carbonate of calcium ... ..	...	...	9·54
Carbonate of magnesium ... ..	...	...	13·96
Carbonate of protoxide of iron... ..	...	...	0·36
Chloride of sodium ... ..	...	...	26·72
Chloride of potassium ... ..	...	...	3·02
Sulphate of sodium ... ..	...	...	5·41
Sulphate of calcium ... ..	...	...	6·11
Alumina ... ..	...	...	1·56

Total solids ... .. 238·81

Free carbonic acid not determined.

*Skeleton analysis of Half-a-pint (10 wid ounces).*

Total Solids.	Antacids.	Salines.	Purgatives.
14·92 gra.	12·24 gra.	1·85 gra.	·35 gra.

This spring and the previous one, with another, Magdeleine, may be considered as being very much of the same character, and as being typical of the strong Vals waters.

H.R.H. PRINCE LEOPOLD will preside at the Annual Festival Dinner of University College, which will be held in Willis's Rooms, on the 20th May.

### THE NEW NAVAL MEDICAL WARRANT.

ELSEWHERE in these columns the terms of the Royal Warrant for the Medical Department of the Navy are given in detail. That document, as it stands, favourable as some of its provisions are, creates in other respects a degree of hesitation in our estimate formed on first perusing it. Perhaps some of the doubts which thus present themselves may dissipate hereafter; and it is by no means unlikely that explanations by “My Lords,” in regard to individual points may hereafter aid this process. In the meantime, however, some such elucidation appears called for as to the following—unless, indeed, it was intended that the apparent disadvantageous terms as indicated are intended to be so in reality—a conclusion not to be hastily or willingly accepted. Thus, although in the case of medical officers whose length of service is less than twenty years, a definite scale of gratuity is laid down, yet the paragraphs which follow appear to leave in the hands of the Admiralty absolute power, as detailed in paragraph 15 and 16, to reduce and otherwise modify the terms of retirement as may seem to themselves good. Whether also an officer voluntarily withdraws from the Service, or has to do so under compulsion, so long as he has not completed twenty years’ service, his widow and children have

no claim to pension or compassionate allowance (paragraph 20)—a most serious and illiberal reservation indeed. Considering that medical officers in the service of the Navy are liable to be at any time thrown upon half-pay by circumstances entirely beyond their own control, as the ship to which they belong being paid off, the provision in the Warrant that the time so spent on half-pay shall count only as one-third service for increased retired pay, and not for any other purpose, is extremely hard and illiberal (paragraph 19 c). In fact, by the operation of this clause, the date at which a medical officer may count upon becoming absolutely entitled to retired pay becomes indefinitely postponed.

Then, again, under paragraph 14, a medical officer whose service is less than twenty years, if he has the misfortune to contract a disability in, but not by, the service, may have granted to him either a gratuity or half-pay, as the Admiralty sees fit. In other words, from the time he accepts service in the Navy he is absolutely, as regards pay, gratuity, and rate of pension, at the mercy of that body as they may think fit to decide—a very vague expression, yet one which bears an important significance when interpreted by the light of what “My Lords” have heretofore thought fit to lay down as their policy towards medical officers. With regard to several points to which a good deal of importance is attached by medical as by other officers, the Warrant is altogether silent. Thus it contains no provision with regard to good-service pensions, to appointments as honorary surgeons and honorary physicians to the Queen, or to honorary distinctions. No doubt it is intended that with regard to these the provisions formerly laid down shall continue in force. Now, however, that an increase has been granted in the army to the number of distinguished service pensions a corresponding measure of liberality ought to be extended to the Navy. As to honorary distinctions, the policy of the authorities towards medical officers in all branches of the public service, has been most illiberal and unfair, considering the nature of the duties performed by them. In the Navy this illiberality has been very marked, nor is a departure from a similar policy in the future indicated in the Order in Council dated April 1, 1881.

### CRAWFORD v. THE BRITISH MEDICAL ASSOCIATION.

THE great Cork Pilocarpine libel case was tried last week, and we trust that we have heard the last of a controversy which has for the last year afforded a perennial source of conversation and discussion to the gossiping little metropolis of the South. We will not on this occasion go into the pitiful details, or describe how a physician of the highest personal character and professional eminence was hounded down for having been a little in advance of his contemporaries, and for having, in an admittedly dangerous case, employed a remedy which, in other more enlightened places, is regarded as a matter of the most ordinary and unquestioned routine. People who have never lived in a country town can form but little idea of the ordeal through which Dr. McNaughton Jones has gone, or can hardly picture to themselves the spectacle of all the dead walls of the city in which he had to practise and live

spread with flaming posters headed "Hospital Torture," *et alia talia*. There were two investigations, one private, by the committee, and the other public, by the corporation; and at the latter the luminous evidence of Dr. George F. Duffey satisfied every reasonable man in Cork, medical and non-medical, that Dr. Jones had simply, in the exercise of his professional discretion, done what any educated Dublin physician would have done under the same circumstances; and that the unfortunate delay which retarded the administration of the pilocarpine until it could no longer do good or harm was due to the omission of the house-surgeon to carry out Dr. Jones's orders. This would have satisfied anyone open to logical reason; but Mr. Crawford appears to have got into his mind a fixed idea—a species of monomania—that Dr. Jones was in the wrong, and accordingly he returned to the charge. When the municipal inquiry closed the Cork Branch of the British Medical Association passed an unanimous vote of sympathy with their oppressed colleague, and in due course transmitted it to the parent association in London, which, as they were bound to do, expressed their opinion on the whole matter in an article in the journal. To everyone reading that article it was evident that the strong, but not too strong, expressions therein, alluded to the two medical men, and to the solicitor who joined in the hunt against Dr. Jones; and in a much lesser degree, if at all, to Mr. Crawford, in whose sad bereavement everyone sympathised. Mr. Crawford, however, thought fit to put the cap on his own head, and brought an action against the *British Medical Journal*, its editor, Mr. Ernest Hart, and also against the *Cork Constitution*, a local paper which copied the article as a matter of general interest.

The case occupied five days on the banks of the Lee last week, and once more the plaintiff and his counsel, Mr. Murphy, Q.C., told the thrice-told tale, which was promptly dissected and torn to pieces by Mr. Porter, Q.C., and Sergeant Heron. The friends of the plaintiff appeared to be under an impression that the article had been written by Dr. Jones, and by him transmitted to London and to the local paper; but Mr. Hart proved conclusively that this article was his sole composition, and that the facts were obtained from the resolution of the Cork Branch, and from the reports of the municipal investigation in the Cork papers; further, that Dr. Jones had not in any way whatever inspired or suggested the article. Dr. Quinlan demonstrated that the child had died of malignant suppressed scarlatina, and that the pilocarpine had nothing to say to the matter. Further, this witness explained at great length the physiological action and properties of pilocarpine, its uses and mode of administration, and proved that in Dublin it has long been a matter of the most ordinary routine. A severe cross-examination failed to shake this testimony, which was warmly commended from the bench by Mr. Justice Barry, and on its termination the jury informed his lordship that they considered it conclusive, and required no more medical evidence on the matter, on which understanding Mr. Porter, Q.C., closed the case.

On the technical question of whether the impeached words exceeded the limits of fair comment the jury disagreed, although, after Mr. Justice Barry's charge, we can hardly see how they could hesitate to find for the defendants. The British Medical Association is a society partly

for the advancement of medical knowledge, and partly for the protection of individual members from unjust attacks. A journal circulating exclusively among the ten thousand members of that association was bound to speak out manfully in behalf of Dr. Jones, and it did so. Milder measures would not have satisfied those members, or, in our opinion, been suitable under the circumstances. Although the result on the technical point is an open one, it is evident that the Cork special jury, by withdrawing the medical aspect of the case from consideration, decided that Dr. Jones was in the right, and that, in the eloquent words of Mr. Justice Barry, whatever the result of the case might be, it would leave no stain on his learning, ability, or devotion to his duty. We sincerely congratulate Dr. Jones on this most satisfactory termination of an ordeal in which he has always commanded the sympathy of the Irish medical profession, of which he is an ornament.

#### THE GARDNER BEQUEST FOR THE BLIND.

THE decision of the Vice-Chancellor, to whom the settlement of the Gardner bequest for the blind was referred, will certainly be received with great satisfaction by those who take an interest in the welfare of this afflicted class. It will be in the recollection of our readers that the late Mr. Gardner, who, throughout his life, manifested much concern in the education of the blind, was led to help on the work of the Royal Normal College, and at his death gave legacies to this and other kindred institutions. He also directed his executors to set aside a sum of £300,000, free of legacy duty, for the benefit of blind persons in England and Wales. This munificent sum he ordered to be invested in the names of a committee of five trustees, who were to employ it in the education of poor blind persons in suitable trades, handicrafts, and professions, especially that of music, and in providing pensions for poor and deserving blind persons incapable of earning their livelihood. All this was admittedly specific, and it might have been supposed that trustees would have had no difficulty in following the directions of the testator.

The Committee appointed were his daughter, Mrs. Richardson Gardner, the Bishop of London for the time being, Lord Kinnaird, the Hon. A. Kinnaird, and Mr. Beaumont, all of whom were apparently agreed as to the desirability of giving special facilities for the musical education of the blind, upon which the testator laid particular stress, but they differed amongst themselves as to how this should be done. Moreover, two of the trustees, Mrs. R. Gardner and Mr. Beaumont, were bent upon spending the greater part of the trust fund on bricks and mortar, and very pertinaciously urged upon their co-trustees a scheme for building an asylum or college at Windsor, which should bear the name of Gardner. This scheme not receiving the approval of the other three trustees, the matter was referred to Vice-Chancellor Malins. This judge took the wise course of placing the matter and the rival schemes (for we hear there were three) in the hands of a barrister of standing, who he authorised to collect and take evidence as to what had already been done in England, on the Continent, and in America, with a view to benefit and educate the blind, so as to enable them to earn their own living by teaching, &c., in short, making

of them useful members of society. An immense mass of valuable information was in this way obtained. A very large number of persons interested in the welfare of the blind came forward and gave evidence of a useful and instructive character. Amongst those who were examined was Professor Fawcett, Dr. Armitage, Sir Charles Trevelyan, Professor Campbell, Mr. Wilkinson, Mr. Jabez Hogg, and many of the superintendents of the various blind asylums throughout the country, all of whom were opposed to spending money on bricks and mortar. The upshot is that the Vice-Chancellor last week decided against the building scheme, and in favour of applying the fund to helping existing institutions. He was convinced, he said, "that there are in London and elsewhere in England numerous institutions of an excellent character, and, further, there is one institution of great merit—the Royal Normal College and Academy of Music for the Blind, in which the testator took a great interest. In my opinion, therefore, in founding a new separate institution, and merging the fund in bricks and mortar and other ways, instead of assisting those established and shown to be useful, there would be great loss. I think it is desirable that the fund should be applied in assisting existing institutions rather than in founding and endowing a new one. I do not propose to exclude the application of a part of the funds to that purpose if it should be found that after sufficiently helping those in existence, there should be enough left to do so. It has been pressed upon me that the testator has not mentioned his desire that the fund should be applied to existing institutions, but neither has he shown any desire to found a new one. He has very wisely allowed the greatest liberty to the committee to do that which, after due inquiry, they should find to be most beneficial." This decision will, we are convinced, in the end be the wisest and best for all concerned in the application of the Trust.

## Notes on Current Topics.

### Lord Beaconsfield's Medical Attendants.

We referred briefly last week to the regrettable public association between Dr. Quain, a physician of the most orthodox type and of the highest professional rank, with Dr. Kidd, a professed homœopath, and therefore necessarily an avowed disbeliever in the scientific medicine of which Dr. Quain is the representative; and as we regard this fraternization as temporary and inevitable, but as a distinctly anomalous condition of things, we must regret that it has not, since we last wrote, come to an end by the restoration of the distinguished patient to convalescence. Indeed, the frequent parade of "consultations" between practitioners who can by no means interchange ideas on equal terms is very painful to the profession, and it would be truly pleasing to them to think that Dr. Quain's ministrations towards Lord Beaconsfield were not in any way subject to modification under the advice of the gentlemen to whom he is acting as consultée. We have said, and we retain the opinion, that under the peculiar and very coercive circumstances we cannot see how Dr. Quain could have refused to meet Dr. Kidd, and we repeat that the public would

have been very angry if so valuable a life as that of Lord Beaconsfield had been imperilled even for a moment by an incompatibility of practitioners, which would not be clearly understood. It appears to us, indeed, that the least creditable place in the false position which both gentlemen occupy is that filled by Dr. Kidd, for he, a professed homœopath, a repudiator of allopathy and all its therapeutics, and an avowed disbeliever in scientific medicine, is now daily engaged practising the abominations of allopathy in association with a physician whom, if consistent, he is bound to regard as a benighted and un instructed delusionist. Dr. Kidd is either an homœopath or no homœopath; and it cannot be regarded as otherwise than culpable for a practitioner to earn a fee to-day by means which he declares to-morrow to be the embodiment of error and ignorance.

We cannot suppose that Dr. Quain is easy in his association with a gentleman engaged in this line of practice, and we are quite sure that he is anxious, as we are, that he should be disconnected from Dr. Kidd, and freed from what we venture to call the professional cloud which at present obscures his lustre.

### The International Medical and Sanitary Exhibition.

THE allotment of space to intending exhibitors is now being rapidly proceeded with, and at the meeting of the committee last week the names of 225 exhibitors were registered, and approved as follows:—Medical section, 115; sanitary section, 94; miscellaneous section, 16. In addition to the wall space and counter space taken, upwards of 1,200 feet frontage of floor space will be allotted to the above exhibitors, representing an area of no less than 8,000 square feet. This area will be occupied by articles which come strictly within the object of the exhibition, the committee having refused all applications for exhibiting curiosities, &c., which too often are added to exhibitions for the purpose of making them more attractive to general visitors without regard to the primary object aimed at. The executive committee of the Parkes Museum of Hygiene may certainly be congratulated on the success which has thus far attended their efforts to organise the first International Exhibition of Hygiene that has been attempted on so large a scale. The list of exhibitors already includes the leading manufacturers in Great Britain and Ireland in connection with the medical industries, and the industries connected with architecture and sanitary engineering, and important exhibits are announced from France, Germany, Austria, Italy, Belgium, Holland, Norway, and the United States.

### Pilocarpine in Uræmia after Scarlatina.

IN *La France Médicale* Dr. Mook relates a case in which hypodermic injection of pilocarpine was successfully employed in albuminuria and uræmic poisoning following scarlatina. The patient, *æt.* 11, had had an attack of scarlatina, and when Dr. Mook saw her was suffering from consecutive albuminuria. The next day, Aug. 2, she complained of headache and nausea, no vomiting, and the amount of albumen was increased. In the course of the day the child vomited and complained of dimness of sight; she answered vaguely; pupils dilated. She

had only passed since the morning a few drops of reddish urine. Ordered a draught with 4 grammes of infusion of jaborandi leaves. Dr. Mook was called again between 2 and 3 the next morning, and found the child absolutely unconscious, hearing nothing; seeing nothing; breathing stertorous. No perspiration. He then injected hypodermically in the hypogastric region 3 milligrammes of hydrochlorate of pilocarpine. In five minutes the child began to expectorate saliva abundantly; the skin became warm and covered with sweat. On seeing the patient again, eight hours later, Dr. M. was told that the linen had been changed twice, being soaked. The patient had slept; the breathing was more quiet; the patient understood what was said, but could see nothing. From this time, however, under digitalis, blisters, &c., the child improved: the sight returned, albumen diminished, the amount of urine increased, and on August 18 was well. It is worthy of note in this case that while jaborandi had no effect, the efficacy of pilocarpine was immediately evident.

#### The International Medical Congress.

As the time of the meeting approaches the evidence of general interest in the Congress becomes increasingly apparent. In several of the sections the number of communications already promised is large enough to fill up the entire time likely to be at their disposal, and these, by contributors whose high scientific character is sufficient guarantee for the merit of their intended papers. The choice of the executive committee of a representative of French medical science to give the fourth of the general addresses, has fallen upon Dr. Maurice Raynaud, a distinguished physician and an accomplished orator, the author of "Le Medecine au temps de Molière," as well as more strictly scientific works of high merit. In Paris and Berlin a lively interest is taken in all that pertains to the Congress by a large number of the hospital physicians and surgeons, and a number of medical men from the provincial towns and schools in France and Germany have conveyed their intention to be present. The Royal College of Surgeons of England have decided to give a *conversazione* in the Hunterian Museum, on Friday, August 5th, and the preparations that are being made, both in respect to public and private hospitality, will not be unworthy of so great an occasion, and one indeed of which so very great expectations have been formed abroad. The Society of Apothecaries of London have liberally granted the sum of £52 10s., to the funds of the Congress, and the Royal College of Surgeons of Ireland the sum of £25, and it is hoped that all intending subscribers to the Congress will signify the amount they wish to give as soon as possible, as otherwise the executive and reception committees are unable to finally decide upon the programme of entertainments, the cost of which for so large a number as that which is expected being necessarily large.

THE Home Secretary "regrets that pressure of parliamentary duties prevents him receiving the proposed deputation respecting the management and affairs of Guy's hospital." We suppose the fact that a member of the late government being on the hospital board, had nothing to do with this refusal.

#### The Royal Society.

THE annual election for 1881 of fifteen Fellows of the Royal Society will take place on June 2nd next. The duty of classing the candidates is first performed by the Council of the Society, and the list is then submitted for the approval of the whole Society at its annual general meeting. Amongst the men of scientific eminence selected for the present year, the medical profession is represented by Dr. J. Syer Bristowe, Senior Physician to St. Thomas's Hospital, Dr. Alexander Macalister, Professor of Surgical and Comparative Anatomy in the University of Dublin, Dr. Ramsay H. Traquair, of Edinburgh, formerly Professor of Zoology in the Royal College of Science, Ireland, and at present Keeper of the Natural History Collections in the Edinburgh Museum. The decoration of these gentlemen will be hailed in the profession as an appropriate recognition of the valuable services rendered by each respectively in the cause of scientific progress.

#### The Census.

WE recently commented on the little use made of the opportunity the taking of the census afforded for acquiring information concerning the national constitution, and expressed regret that more advantageous employment of the means at hand was not made. Since the actual operation has been completed, however, there have been reported so many instances of neglect even to comply with the first essentials to obtaining an accurate return, that but little reliance can be placed in the figures with which, by and bye, we shall be presented as the result of the enumeration. In many cases, judging from complaints forwarded to daily contemporaries, whole streets have been omitted by the census officials, and we know of more than one establishment where no form was, or has been, left to be filled in. The imperfections of the latest census, indeed, are even at this early period so apparent that they cannot but add force to the lament often made in our pages and other places, that, in appointing a Registrar-General the late Government selected an untried and untrained man, rather than the one whom every consideration suggested as the fittest candidate for the post. It is not, perhaps, surprising that the census should be marred by the mishaps that go to make it almost useless as a register of population; but, none the less, it is intensely mortifying that so valuable a source of important information should be docked of any of its usefulness, by reason of a blunder that ought never to have been made. The supplementary census it is now necessary to take in numerous quarters will hardly be such as to satisfy the requirements to be made of it; and at best the whole affair is, it almost appears, an unfortunate but well-intentioned failure.

#### Judicial Torture.

THE proceedings in connection with a prominent law case, now in course of hearing at Westminster, bring into strong relief certain practices commonly prevailed in by examining counsel, which are calculated to inflict serious injury on the nervous organisms possessed by many witnesses submitted to the ordeal of a searching cross-examination. The privileges enjoyed by counsel are of a kind to protect him from any consequences that would certainly follow to him were he not covered by

the security given him while under the eye of the judge. He may, in the exercise of his functions, put any question to a shrinking witness, and, as we know by frequent experience, he does often so interrogate his victim as to call forth the most explosive utterances of disgust, which however, are forthwith prohibited as being "contempt of court." It seems a most unjustifiable outrage that a man should be permitted to address to a lady questions calculated to excite her indignant denial, and then to deny the unhappy witness the privilege of expressing the pent-up loathing of her tormentor's insidious suggestiveness. The consequences of any continued examination of this kind are of a nature to seriously injure her nervous system, and produce effects that may be more or less lasting. There are few occasions on which it is not apparent how far this terrorism can be pursued with impunity, and in the interests of humanity it would seem that the protection of the judge should be extended to witnesses against examining counsel, at least as much as to the latter against the object of their attack.

#### The Proposed Royal Commission.

THE Commission on the Medical Acts, which as first proposed was to consist solely of lay members, is, in accordance with the almost universal desire expressed in professional circles to be recast to include medical representatives also. It is to be hoped the selection will include not only those interested directly in associations and corporations, but those also who are, as general practitioners, well acquainted with the needs of the rank and file. There can be no doubt that a strong and able commission can be selected by judicious consideration of the merits of the question to be decided, and a hope may now be fairly entertained that as a result of the coming sessions of the commission, there will be formulated a scheme embodying the best propositions that have, from time to time, been made.

#### The Faraday Lecture.

THE circumstances attending the Faraday lecture of 1881 were unusually important on Wednesday last, from the fact that Professor Helmholtz occupied the post of orator. The subject chosen was "The Modern Development of Faraday's Conception of Electricity," and the discourse was an eloquent exposition of the labours achieved by the famous physicist, whose memory was perpetuated by the gathering assembled to listen to the greatest of his living successors. The enthusiastic reception accorded to Professor Helmholtz at each one of his public appearances in England will prove a grateful tribute of the admiration and respect in which he is held in this country, and will be duly appreciated by him in this way.

#### The Health of Dublin for the Month of March.

FROM the official Report of the Superintendent to the Dublin Corporation, we find that the death-rate continues high, but the high mortality is not due to the prevalence of zymotic diseases. In the whole registration area the number of deaths from all zymotic diseases in March, during the last ten years, was 147, whilst last month

these diseases caused only 98 deaths, of which 61 were chargeable to the city. It is strange that whilst the zymotic death-rate in the city was only 2.45, it was 3.7 in the suburban districts. If we compare the March of 1880 with that of 1881, the better state of public health in the latter will be evident.

It is to be noted, too, that the zymotic death-rate was also unusually low in February, and that the zymotic death-rate in January and February, 1881, was much below the average of these months for many years past. The zymotic death-rate in March was, in the city, the lowest recorded.

During the month magistrates' orders were obtained for the closing of 131 houses unfit for habitation.

Thirty-three other houses unfit for habitation were actually detenanted and closed.

Forty-six rooms in various houses, and six cellars, were also closed.

#### The International Pharmaceutical Congress.

THE *Pharmaceutical Journal* announces that the projected meeting of this Congress this year in London may now be looked forward to as a certainty. Already a sufficient number of foreign pharmacists have announced their intention to be present on that occasion to make it likely that the meeting will be a successful one.

The Committee appointed to act as the executive body in making the necessary arrangements for the Congress has already held two meetings, at which various preliminary steps of organisation have been taken. The time for holding the three business meetings of the Congress has been fixed for the 1st, 2nd, and 3rd of August, and that on the 30th of July there will be a *conversazione* at the house of the Pharmaceutical Society for the official reception of visitors, and for the purpose of personal introductions. On the following Monday the first business meeting will commence at 11 o'clock, and after the delivery of an address by the President of the Pharmaceutical Society, welcoming the visitors, a president and officers will be elected to carry out the special business of the Congress.

A programme of the proceedings has been drawn up provisionally, and in the course of a few days it will be distributed, both abroad and at home, among those who may be expected to take part in the Congress. It is proposed that the subjects to be discussed shall be arranged under three separate heads, one day being devoted to each. These subjects are pharmaceutical education, Pharmacopœia revision, and the equalisation of the strength of official preparations containing potent drugs. This last-named subject may be regarded as the most feasible step towards the establishment of an International Pharmacopœia.

DR. HAMILTON, of Dromahair, and Dr. Lucas, were last week presented with medals from the Humane Society, for saving the life of a boy who fell into Lough Gill.

LUNACY would seem to be especially rife in Lancashire, if we take into consideration the fact the Rainhill magistrates propose to extend the asylum to admit 1,000 more patients at a cost of £120,000.

**Iodide of Ethyl and Pilocarpin in Asthma.**

THE *Chicago Medical Journal* says that iodide of ethyl has been used successfully by Dr. Brower, after all other remedies had failed. The patient was a boy of fifteen, with an inherited nervous weakness. The dose employed was six drops. The drug relieved the paroxysms and lessened the intervals between them. Dr. Barkhart finds pilocarpin curative in asthmatic cases complicated with chronic bronchitis.

THE trial of the indictment for libel preferred by the St. John's Hospital for Skin Diseases against Dr. Hoggan and the *Medical Press and Circular*, which was postponed by the length of the Lawson-Labouchere case, will say the *Charity Record*, take place during the Easter sittings.

At the Royal College of Surgeons of England, Mr. Jonathan Hutchinson will deliver six lectures on the Laws of Inheritance in Relation to Disease; and Dr. Gerald F. Yeo three lectures on the Contractile Tissues. Both courses will be delivered in June, on days which will be announced.

A MAN and woman holding out as Professor Mayfield and Eugenie Lilly, "American rheumatic doctors," were charged at Bristol last Thursday, with unlawfully pretending to be general practitioners. It was proved that the man had prescribed and administered medicines in Bristol, where he had a shop, from which he absconded when summoned. The wife was discharged, and the husband fined £20, or in default two months' hard labour.

In the principal foreign cities, the rates of mortality per week, according to the most recent official returns, were:—Calcutta 30, Bombay 30, Madras 45; Paris 32; Geneva 22; Brussels 23; Amsterdam 29, Rotterdam 25; The Hague 19; Copenhagen 17, Stockholm 28, Christiania 26; St. Petersburg 56; Berlin 24, Hamburg 27, Dresden 23, Breslau 41, Munich 39; Vienna 30; Buda-Pesth 30; Rome 32; Turin 34, Venice 26; Alexandria 36; New York 31, Brooklyn 22, Philadelphia 23, Baltimore 20 per 1,000 of the population.

Of diseases of the zymotic class in the principal large towns scarlet fever showed the largest proportional fatality in Sunderland and Wolverhampton; and whooping-cough in Portsmouth, Newcastle-upon-Tyne, and Liverpool. Of the 32 deaths referred to diphtheria in the twenty towns, 10 occurred in London, 10 in Glasgow, 2 in Edinburgh, 2 in Portsmouth, 2 in Birmingham, and 2 in Liverpool. The death-rate from fever was highest in Wolverhampton. Small-pox caused 60 more deaths in London and its suburban districts, 1 in Newcastle-upon-Tyne, and none in any of the other large towns.

**BUXBURN—MEDICAL APPOINTMENT.**—Mr. David Mavor, M.B. and C.M. Aberdeen Univ., has been appointed as medical officer of Newhills and Dyce Medical Association in succession to Dr. Carlyle, who recently resigned. Dr. Mavor has for some time filled a parochial appointment in Dalrymple, Ayrshire.

**Scotland.**

(FROM OUR NORTHERN CORRESPONDENT.)

**ROYAL COLLEGE OF SURGEONS, EDINBURGH—ELECTION OF EXAMINERS.**—At the last meeting of the College two examiners were elected to fill the vacancies caused by the death of Dr. P. D. Handyside, and the resignation of Dr. Argyll Robertson. The three candidates were Mr. Symington, Lecturer on Anatomy, Minto House, Dr. H. P. Maclaren, and Dr. Macnair. Mr. Symington was the candidate put forward by those in the College who wish to see their ancient College taking a foremost position in the necessary medical reforms of the day. It appears that there is not a single lecturer or teacher on midwifery on the board of examiners, and the weakness on this subject it was proposed to remove by electing two gentlemen, one of whom does not practise midwifery, and the other is not even a member of the Obstetrical Society, a qualification which we believe can be obtained by the annual payment of five shillings. Mr. Symington's election is the death-blow to the "use and wont" system under which an examiner was selected, not on account of any especial knowledge he might possess, but of his ignorance of the subject on which he was appointed to examine. Mr. Symington will, we believe, refuse to examine on any other subjects than anatomy and physiology, which, from his position as a teacher, he is eminently qualified to do. Dr. P. H. Maclaren, the other examiner selected, will of course examine on any and every subject.

**QUACK ADVERTISEMENTS.**—Since the recent exposure of the scandalous traffic in these advertisements, in connection with the *Daily Telegraph*, respectable journalists will doubtless exercise a guarded supervision in this department. There can be no doubt that many newspapers knowingly insert these advertisements at an advanced rate, while in others they are found possibly owing to carelessness. The extent to which young men especially are tormented in mind, and filched in purse by this widespread system of fraud, is hardly sufficiently appreciated. The matter is indeed one for legislation. Newspapers that wilfully insert these advertisements must morally be held as participators in the fraud, and conspirators against the public weal, and should be held in merited opprobrium. To-day the case of a young man, in good enough health, came under our notice, who was robbed of £7 sterling, in being persuaded to purchase a sham electric apparatus, which he soon threw away, besides being for many years perplexed in mind by visionary fears suggested by these harpies abounding in the metropolis. The advertisement which led to this appeared, we regret to say, in a respectable Glasgow daily paper. We hope this will not occur again.

**MILK POISONING IN ABERDEEN.**—An epidemic of an anomalous febrile disorder broke out in Aberdeen in the beginning of the present month. The disease was ushered in by a severe rigor, which was followed by headache, backache, high temperature, and sore throat; the tonsils being deeply injected, and the lymphatics in the neck swollen and exceedingly painful. In no case has there been—so far as we have been able to learn—any false membrane on the mucous covering of the throat. In most of the cases the symptoms gradually abated, and convalescence was established on the fourth day, but in some relapses took place, and the symptoms re-appeared. The disease was chiefly met with in the West end of the town, and in some households seven, nine, twelve, members were affected at the same time. Inquiry has shown that, in all the cases we have heard of, the milk

supply was obtained from a large dairy farm in the neighbourhood of the town, and this suggests very strongly the idea that the source of the poison was in the milk. The cows have been inspected, but they were found to be perfectly healthy, and the water supply and other arrangements of the farm were unexceptionable, and as yet no explanation of the occurrence has been advanced, excepting a suggestion to the effect that it may have originated in disease of the turnips on which the animals were fed. We understand that specimens of the milk have been submitted to analysis by an expert, and we trust that a microscopic examination of blood taken from some of the affected persons has not been neglected, as the presence or absence of bacteria would form an interesting and instructive feature.

**EDINBURGH ROYAL MATERNITY AND SIMPSON MEMORIAL HOSPITAL.**—For the quarter beginning 1st May, Dr. Keiller will be medical officer on duty in succession to Dr. Angus Macdonald. The present house-surgeons, James W. B. Hodadon, L.R.C.P. and S.E., and Arthur P. Wells, M.R.C.S. Lond., will then be succeeded by G. W. W. Ashdown, M.B., M.C., and Alexander Bowie, L.R.C.P. and S. Edin., who have been appointed house-surgeons for that quarter.

**ABERDEEN UNIVERSITY—SHEPHERD GOLD MEDAL.**—The Shepherd Gold Medal in Surgery has been gained at the University of Aberdeen by Thomas Wardrop Griffith, Aberdeen, who gained 98 per cent. of the marks in the examination, which is restricted to second year's students.

**THE HELENSBURGH SEWAGE QUESTION.**—An impression having prevailed that recent epidemics in and around Helensburgh were due to emanations from sewage deposited along the coast, analysis of mud, &c., from foreshore and other places were conducted, at the instance of the local authority, by Dr. Wallace of Glasgow, and Dr. Stevenson Macadam of Edinburgh. The full reports are not yet published, but it already transpires that the analyses are such as to exceed the expectations of those who maintained throughout the entire absence of sewage from the shore, and when compared with other towns to place Helensburgh in a foremost position.

**ANDERSON'S COLLEGE.—ELECTION OF A PROFESSOR OF MIDWIFERY.**—At a *pro re nata* meeting of the trustees of this school, held on the 4th inst., Dr. Abraham Wallace, of Glasgow, was, by a large majority of votes, elected "Professor" of Midwifery, in room of the late Dr. J. G. Wilson. The candidates were Dr. Murdoch Cameron, Dr. W. L. Reid, Dr. S. Sloan, Dr. A. T. Thomson, and Dr. Wallace. The competition was a very keen one.

**UNIVERSITY OF GLASGOW.—CLOSE OF THE MEDICAL SESSION.**—The Winter Session of the Medical Faculty of this University was brought to a close on the 6th inst.

## Literature.

### PHYSIOLOGY. (a)

(1.) **DR. ASHBY'S** "Notes on Physiology" having reached a second edition is some proof that the work has been found of service to a class of students who prefer to "get up" examination work in examination form. The book is literally "notes," but we can hardly accord it unqualified praise, even as a note book. While it contains probably as much information as a student presenting himself at the Royal College of Surgeons, or the Apotheccaries' Hall, must show evidence of possessing, it is yet wholly inadequate to do more than convey

the briefest outline of scientific physiology. Exception too, may well be taken to the way in which the chapters are put together; there is a confusion of grammatical rules often apparent that is trying to the cultivated reader; and the degree of condensation necessitated by the small size of the volume not unfrequently may create confusion as to facts, in the minds of little-informed students. It were better at once to recognize the fact that a treatise on physiology cannot be compressed within the limits of a pocket manual, and restrict the aim of publications having this character to *indicating* what ought to be learnt rather than describing it. To a student already familiar with the elements of physiology, Dr. Ashby's little book will be useful; to any other class of readers it may be injurious.

(2.) Since the appearance of Dr. Gamgee's translation of "Hermann's Physiology," no more thorough or more severely exact work than the "Text-book of Physiological Chemistry" has issued from the press on any medico-scientific subject. The volume is a triumphant refutation of the pessimist view that original research no longer finds a home in England; it is a magnificent proof that English labour is as capable of producing good and lasting work as are the efforts of our Continental brethren. Like Hermann's text-book, Dr. Gamgee's manual is "stiff" in the sense that it must be diligently and conscientiously studied—it cannot be read simply; its perusal is an intellectual task, but it is equally also an intellectual treat.

This first volume is occupied entirely with the discussion of the elementary tissues of the body, the proteids forming the subject of the first chapter; their general characters, chemical reactions, chief forces, decomposition, and theoretical constitution being entered on. The views of Schutzenberger, are very briefly stated, they, in the opinion of our author, being, as yet, of interest to the chemist in the way of suggestion rather than to the biologist. Pflüger's conception of the constitution of proteid material is shortly explained on p. 20, but we think a greater space might have been devoted with advantage to propositions which have probably more of the element of truth to recommend them than many of the fanciful conjectures invented to elucidate the metabolic processes in the living organism. This objection, however, cannot be applied to the 2nd, 3rd, and 4th chapters, which are devoted to the subjects of "Blood," "Blood Changes in Diseases," and "Description of Certain Methods of Research." On pathological changes in the blood, Dr. Gamgee has a good deal to say that must prove absorbingly interesting to the medical reader. The importance of the cellular elements of the body in determining the nature of disease, and of their relation to functional endowments, is accepted as determining the view that "disease will, in all probability, depend primarily on modifications in processes of the cells, rather than of the fluid whence cells obtain their nourishment, and we shall be quite prepared to find (1) that a morbid process may seriously interfere with organs where functions are essential to life, without influencing the composition of blood in a manner perceptible to our methods of chemical and microscopical analysis, however delicate they may be, and (2) that when a marked change is revealed by these methods of inquiry, it must be a difficult matter to trace the component causes, of which the change is the resultant effect." These propositions are elaborated in the following pages, and in a way to throw abundant light on many obscure points that arise to puzzle the practitioner in his daily experiences. The variations that occur in the proportion of the principal blood-constituents in the chief diseases, are fully described. The fourth chapter is taken up with descriptions of apparatus and modes of research, employed in investigations on the blood: it adds much important detail necessarily omitted from even the best physiological handbooks, and contains hints and descriptions valuable from a medico-legal point of view. The lymph and the chyle are dealt with in chapter v, the sixth being given to pus, and the seventh, to the connective tissues. In the latter the changes undergone by bone in disease are treated, osteo-malacia and rachitis, caries and necrosis; this section being followed by dissections for the quantitative analysis of bone. Tooth also is considered here. The final chapters are occupied by a discussion of the physio-chemistry of epithelial, contractile, and nervous tissues; and a chemical history of certain of the peripheral terminations of the nervous system, and accessory tissues, &c. To protagonist, Professor Gamgee gives considerable space, and details a series of laborious investigations conducted in the Owens College Laboratory with the object of settling the vexed question of its in-

(a) 1. "Notes on Physiology." By Henry Ashby, M.D. Lond. Second Edition. Longmans. 1880.

(2) "A Text-book of Physiological Chemistry of the Animal Body." By Arthur Gamgee, M.D., F.R.S. Vol. I. Macmillan. 1880.

dependent existence. The result of the experiments, the record of which is a testimony of the care with which they were performed, is conclusively in favour of Oscar Liebreich's discovery; and Mr. Gamgee is convinced "that unquestionably the only well characterised phosphorised proximate principle which can, with our present methods, be separated with certainty, and whose existence will be confirmed by future researches is protogon."

As we have said, this book is incomparably the ablest work on physiological chemistry in the English language: for the medical man it has an especial value, rather as a work of reference than for continuous reading; as a reference volume it is invaluable.

#### TRANSACTIONS OF THE PATHOLOGICAL SOCIETY OF LONDON. (a)

SINCE their commencement in Dublin, pathological societies have wonderfully increased. There is no town or city now of any size which may not be said to have its society, and as London is the largest city in the world, so its Pathological Society is the largest, and now reckons 600 members; and its work is in proportion with its members. As far as we know, no other society of the kind issues so goodly a volume, and that yearly. It has been our lot to notice the Transactions of this Society for several years, and we proceed to do so once again. But on the present occasion we shall not be able to carry out our wishes to the same extent as formerly.

There are two points we must, *in limine*, notice here. The first is the death of Dr. Murchison, which occurred shortly before the issue of the previous volume, and could not then be noticed. We are glad to see that a well written, though brief, sketch of this lamented gentleman is in the present volume, and, as it says—"For a long time to come the loss of Dr. Murchison must seem irreparable." He joined the Society in 1854; worked in it for 25 years; held the offices, in turn, of Hon. Sec., Treasurer, and President; and contributed 150 specimens to its proceedings." Such industry as this could scarcely be surpassed, and if it had occurred in Dublin, a bust, at least, of such a man would have been set up in the rooms of the Society. We would suggest this being even yet done.

The second point we would speak of is the plan lately devised of exhibiting specimens by what is called "cards." The want of time was felt so much, owing to the number of specimens to be exhibited, that this means was adopted, and has been found to work well. It consists in the morbid specimen being, when practicable, fixed to the card, and the latter having a brief account of the specimen written on it. In this state it is laid before the meeting, without any verbal account of it, and members can at a glance see whether it is a subject which would interest them. For ourselves, we should have some misgivings as to whether so much material could with advantage be in this way compressed. It is stated, however, to have worked well, and so we leave the matter for the present.

Like previous volumes, this one is divided into sections, the first being on "Diseases of the Nervous System." The first case is entitled "Ramifying Cyst in the Brain, associated with a Congenital Malformation of Some of the Cerebral Vessels," by W. Ewart, M.B. This is an interesting case, though too long for insertion here. The strangest point about it seems to us to be that the patient, a man of 30, never exhibited any symptoms till about two years before his death. His illness began with severe headache and vomiting. The post-mortem showed that the cerebral disease existed long before there were any signs exhibited by the patient. No. 2, by J. Harris, M.D., and Alban Doran, is a "Spinal Cord from a Case of Tetanus following Ovariectomy." On this case we observe that any morbid change found in the cord was confined to the cervical and upper dorsal regions, and seemed to be caused by inflammatory action. Lockart Clarke's investigations point in the same direction. Has our treatment been guided by such facts?—for we think we may assume they are facts. For ourselves, we would not hesitate a moment in the use of mercury, rapidly poured into the system; nor would this prevent the use of other treatment. But the question is

(a) "Transactions of the Pathological Society of London." Volume xxxi. Comprising the Report of the Proceedings for the Session 1879-80. London: Printed for the Society by J. E. Adlard, Bartholomew Close. 1880. Pp. 408.

too long to enter upon here. We would observe further on this case that we think it ought to have been called "Trismus," not "Tetanus." It is to be noted that the abdominal muscles were not involved, nor the lower extremities, and it is in this form that the disease shows itself in females. It may appear a strange statement, but it is nevertheless true, that whilst we have seen a large number of cases of tetanus in men, we have never seen it, except as trismus, in women. We have asked, too, parties who had the largest opportunities for seeing the disease, and they all agreed that tetanus, in its regular form, had scarcely come under their notice in females. We consider this a very important point, hard though it be to explain. No. 4, by J. Hutchinson, F.R.C.S., is a case where it is supposed the roots of the brachial plexus were ruptured. For surgeons this is an interesting case.

We are obliged to omit many cases of more or less interest amongst the Diseases of the Organs of Respiration. Amongst those of the Circulation we must notice a very remarkable one by J. B. Peacock, M.D., for Thomas Fisher. It is headed "Case of Rupture of Right Ventricle of the Heart." A man of 25, an athlete, and famous for his great strength, after being partially intoxicated, got into a fight with another, in which he received a severe blow on the epigastrium which knocked him down. While on the ground he was kicked, became unconscious, and died forty minutes afterwards. A rupture 3½ inches long was found in the right ventricle, and through it the pericardium was filled with blood. The right eyeball was ruptured, and the bones at the right temple fractured; but there was no displacement nor any clot on the brain. The texture of the heart was, in places, fatty, and "much fat" was on its surface. The valves were healthy. This seems to us a very remarkable case. That, with such a state of the heart the man should have been an athlete is strange, even though there are enough of cases on record to prove to what an extent degeneration may exist, and yet not interfere with the physical strength. Whether it was the blow from the fist which ruptured the organ admits of question; it may have been a kick as he lay on the ground. And we think the injury done to the eye and neighbourhood was most probably due to the same cause. In any aspect in which we look at this case, we cannot but consider it as a very remarkable one, and possibly unique. No. 7, by H. J. Butlin, is also a remarkable case, and given as "Fibroid Patch of Inter-ventricular Septum of Heart; Blood-clots in Brachial, Hepatic, and Superior Mesenteric Arteries; Gangrene of Portion of Jejunum." The affection of the arteries was of the nature of clots which seem to have caused the disease that existed, for the index and middle fingers of the left hand were gangrenous at their tips, whilst the jejunum was very soft, easily torn by the slightest force, and much discoloured; and at its upper part perforated by two holes, which had caused recent peritonitis. The previous history of the case is unfortunately wanting. We should like the author to have told us the state of the arterial coats where the clots existed, as it would have helped to throw light on this obscure case.

To No. 12, by F. T. Eve, we would also direct attention. It is entitled "A Case of so-called Aneurism by Anastomosis of the Ear," and is illustrated by a very fine coloured drawing. It existed from birth, and grew slowly till the girl was twenty-one years of age, when it was removed by operation, and the girl got well.

Amongst the Diseases of the Organs of Digestion we would direct attention to No. 3, by N. Moore, M.D., entitled "Ulceration of Stomach and Duodenum." This is a valuable contribution, and gives the statistics of twelve cases of ulceration of the stomach, and one of the duodenum, the latter, however, not caused by a burn. Contrary to what is usually thought, the majority of these cases occurred in men. To No. 9, by F. Taylor, M.D., we would also call attention, being an interesting case of Cirrhosis of the Liver in a child. The case extended over a period of nearly three years. No. 12, by J. Conpland, M.D., is one of "Primary Cancer of the Gall Bladder." This case is remarkable, inasmuch as the disease seems to have been confined to the gall bladder, and had attained the size of a cocoon. No. 13, by N. Moon, M.D., is also a case of "Cancer (probably primary) of the Gall Bladder;" but here the neighbouring glands were also involved. It is to be noted of these cases that in each the stomach was much dilated.

Amongst the Diseases of the Genito-urinary Organs, No. 7,

W. A. Meredith, is worth noting. It is one of "Ovarian Cyst which had Ruptured repeatedly during a Period of Nine Years prior to its Removal." In the first instance the cyst was tapped, and twenty pints of fluid drawn off. When it gathered again, at the end of four months, a severe attack of pain occurred near the seat of the puncture, and within twenty-four hours the shape of the tumour changed, and she began to pass large quantities of clear urine. This went on four days, when all signs of the tumour had disappeared. This process went on three or four times each year, and the entire number of ruptures reached to thirty-four times. This is a very remarkable case. An analogous one came under our own notice—with this exception, that in place of the tumour bursting into the peritoneum, it burst into the vagina, and so Nature relieved herself. The case went on many years, and the patient ultimately died of another disease. No. 8, by P. Swain, will interest surgeons. It is an example of "Calculus Removed by Supra-pubic Lithotomy," and occurred in a girl of ten years of age; the nucleus of the stone was a hair-pin, which had slipped into the bladder, and the stone (of which there is a very good drawing) was so large that it could neither be crushed nor removed in the usual way, by dilatation; and so the operation named was performed, and with entire success. The hair-pin had perforated the bladder, and caused abscess. No 17, by W. Ewart, M.B., is a rare example of miliary tubercle existing in the fundus of the bladder, and nowhere else. The specimen was found in a girl of twenty, who died of hæmorrhage into the pons varolii, and who had granular kidneys and hypertrophy of the left heart. The tubercles were chiefly at the fundus of the bladder.

Though the remaining part of the volume contains much that is valuable and of interest, we are obliged to stop here. We consider, however, we have brought forward enough to prove that this volume is at least equal to any of its predecessors, and that its perusal will well repay the reader. We may state that the number of card specimens is very considerable, and this plan, so far, seems to work well. As usual the volume is very well brought out, and is illustrated by a number of well-executed drawings, together with some coloured plates.

#### A CHRONOLOGY OF MEDICINE, ANCIENT, MEDIÆVAL, AND MODERN. (a)

A GOOD deal may be learnt from the perusal of this curious and interesting book. We hear much now of hygiene and sanitary science, and are ready enough to contrast the enlightenment of this, our day, with the, to some extent assumed, darkness and ignorance of bygone ages. Education and School Board inspectors are active enough (many poor overwrought women, glad of the little aid of a growing daughter in helping to mind the baby, would say a too much officious and meddling), but yet it seems that Mr. Richards is acquainted with places where a faith in witchcraft still prevails, for he says that only last week a poor old woman in Cornwall was carried to her grave by men in their shirt-sleeves because she was believed to have bewitched several people.

The reader will do well to look at (p. 171) "An Office of Health for London," which is the Report of the Royal College of Physicians, dated August, 1637, "on all such annoyances as they conceive likely to increase the sickness in this populous city." After detailing eleven active sources of disease, the College suggests the formation of a Commission or Office of Health, such as has been found useful in Spain and Italy.

Medicine in Greece and Rome is briefly discussed, and we have chapters on quacks and quackery, medical advertisers, and a long list of their remarkable advertisements. Midwives and midwifery are disposed of chiefly in a large illustration representing the birth of Richard Beauchamp, Earl of Warwick, in 1381. The history of the apothecaries and the grocers, and the barbers and surgeons, are neither of them forgotten, and the work concludes with some short notices of men who have advanced medicine, with well-executed portraits of many of these.

(a) "A Chronology of Medicine, Ancient, Mediæval, and Modern." Being a Historical, an Antiquarian, and a Curious Survey of the Birth and Growth of Medicine from the Earliest Times to the Present Day." By John Morgan Richards. London: Baillière, Tindall, & Cox, 20 King William Street, Strand, is, Madrid. 1880. Illustrated by the Typographic Etching Company. Pp. 314.

Mr. Morgan Richard's book is extremely well got up, and he has evidently taken great pains in its preparation. Nearly all the portraits have been taken (by permission) from the collections preserved in the library of the Royal College of Surgeons. The book may well find a place in the library of all interested in possessing a short and pleasantly written outline of the development and progress of the science and art of medicine.

#### THE NEW PRESIDENT OF THE ROYAL COLLEGE OF PHYSICIANS.

AT a meeting of the Censors and Fellows of the Royal College of Physicians of London, held pursuant to charter on the Monday preceding Easter, Sir William Jenner, Bart., K.C.B., was unanimously elected president. By many it was thought that the outgoing president, Sir Risdon Bennett, would have been re-elected, in consequence of the meeting of the International Medical Congress in London this year, at the preliminary meetings of which he has taken so active a part; but as that gentleman had already served five years of office, it was not deemed advisable to make any unusual departure, and so the honour has fallen on Sir William Jenner, than whom no Fellow of the College is more worthy.

#### Correspondence.

##### DEBATED POINTS IN SYPHILITIC PATHOLOGY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In a former number of your esteemed journal I have called attention to one of the points relative to syphilitic pathology, yet unsettled—viz., the nature of the primary lesion. Several letters which have appeared in your columns show that I was right in so doing. London and Paris disagree on this point.

I would now advert shortly to another moot point in the pathology of syphilis, and that is, the nature and origin of those distressing cases of stricture and ulceration of the rectum which form such a sad feature of that common disease. In Paris the writings of MM. Gosselin and Desprès have made us aware that some men of great experience hold the view that the majority of strictures and ulceration of the rectum which ensue in consequence of contamination from contagious sources are due to the irritation produced in the rectum by the presence of soft sores in the neighbourhood. M. Desprès has on one occasion called my attention to this view when I visited the Hôpital Cochin.

For my own part, my observation of such strictures of the rectum is quite contrary to that of these able surgeons. In my opinion, many ulcers of the rectum and strictures of that part are due to tertiary syphilis or to secondary eruptions—mucous tubercles—in the neighbourhood. When the ulceration is secondary in its character, it sometimes only affects the mucous membrane of the rectum; but when the disease is caused by tertiary, or "gummy," infiltration, the sub-mucous connective tissue is first of all implicated, and the ulceration is, therefore, deeper, and far more intractable.

When ulceration of the rectum occurs in company with mucous tubercles it is often easily enough cured by touching with nitrate of silver, or other local means; but, when it is tertiary in character, we have, indeed, one of the most intractable and fatal affections which syphilis causes. I have seen a good number of women die from stricture of the rectum of tertiary character. Iodide of potassium, or mercury, do not seem to have much power in absorbing the syphilitic products in this affection of the rectum; and, as a rule, these cases do very ill. I have seen some occur so soon as two years after the occurrence of the hard sore. Nearly 90 per cent. of such syphilitic strictures of the rectum occur in women.

I should be pleased to know whether this is the experience of other observers.

Yours obediently,

CHARLES R. DRYSDALE, M.D.

## NOTICES TO CORRESPONDENTS.

**FOR CORRESPONDENTS** requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

**LOCAL REPORTS AND NEWS.**—Correspondents desirous of drawing attention to these, are requested kindly to mark the newspapers when sending them to the Editor.

**EASTER HOLIDAYS.**—Authors of papers, correspondents, and others will much oblige by forwarding corrected proofs, communications, &c., by earliest post for next number in order to give the printing staff a day's holiday.

**COMPLIMENTARY.**—"To see ourselves as others see us," especially if it be in a favourable light, is at all times agreeable. The following description of us appeared in the last number of the *American Therapeutic Gazette*, published at Detroit, for which expression of opinion we beg to thank its Editor. "*Medical Press and Circular*. This is a British medical weekly. Like most of the other British medical journals its Editor is *incoy*. It is issued both from London, England, and Dublin, Ireland. The *Medical Press and Circular* is a journal of a superior order of merit, ranking with the leading medical periodicals in the English language. It is printed on very heavy tinted paper, and is a model of typographical execution."

**ENQUIRER.**—The matriculation list has not yet been sent us. The examinations for the Primary at the Royal College of Surgeons of England commenced last week.

**ASCULAPTUS asks (1)** The first steps to take in order to get a dispensary and residence where there is at present a wretched one. I can recommend a suitable place to be purchased. Where could I get copies of the Act 42 and 43, Vic. cap. 25?

**Answer**—See the Act, page 601 "Irish Medical Directory" for 1881. The Board of Guardians must first come to terms with the owner of the land (or of the house if it be intended to improve one already built). Then an application must be made to the L. G. B. for a certificate, (c) that a new dispensary is necessary; (b) that the proposed building is suitable. Upon which the L. G. B., if necessary, holds an inquiry. Having obtained the certificate, the Guardians apply to the Board of Works who lend the money at  $\frac{3}{4}$  per cent., repayable in thirty-five years by an annual rent charge of 25 per cent. on the money advanced.

**2.** What remedy has a dispensary doctor who can't recover his legal fees? Supposing he leaves a district where money be due to him can he sue through an attorney or must he prove the debt in person?

**Answer**—He must, no matter what the nature of the debt may be, prove his case by his own evidence, and will only be allowed half his costs and expenses if the debt be a small one. The county court law of Ireland is extremely bad and very inconvenient to claimants resident at a distance.

**3.** Must I sue in the same way for money due for an inquest case which a coroner disputes, though the medical man gave sworn evidence?

**Answer**—Yes, or you may appeal to the grand jury or the judge of assizes.

**4.** Is the clerk of union bound to supply a notice board for a dispensary where the present one is unfit for use?

**Answer**—Yes, see Dispensary Regulation, Article 4, "Irish Medical Directory," page 254.

**5.** In a district where there is a paid midwife if I get a red ticket to a midwifery case, and the people refuse to summon her, am I bound to attend before or with her, or am I justified in refusing unless she says I am required?

**Answer**—The medical officer's responsibility upon a red ticket is not the least degree less because there is a paid midwife in the district. He must attend and make every provision for the safety of the patient; he may, if he pleases, put the midwife in charge, but he will still be responsible for any mischance.—ED. M. P. & C.

**MR. HARRINGTON.**—Letter has been forwarded to the proper quarter.

**ROYAL COLLEGE OF SURGEONS IN IRELAND.**—The annual distribution of prizes to the students who were successful at the examinations held at the close of the winter session in the School of Surgery took place on Monday, April 4. The chair was occupied by Dr. Alfred H. McClintock, President of the College. The President, in opening the proceedings, expressed the pleasure it gave him to attend upon such an occasion, which reminded him of a similar one thirty-nine years ago, when he also took part in receiving the awards of the College. The following prizes were then distributed:—First Year's Class: First prize, gold medal, and £10, Michael T. Yarr; second prize, £10, W. D. Waterhouse, LL.D. Second Year's Class: First prize, £12, Austin M. Cooper; second prize, £8, Myer M. Dutch. Third Year's Class: First prize, £10, W. B. Stokes; second prize, £8, W. L. Simms; third prize, £2, J. W. Kister. On the motion of Dr. Mapother, a vote of thanks was passed to the President. The proceedings then terminated.

## THE ACCIDENT TO MR. JOLLIFFE TUFNELL.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

DEAR SIR.—So many kind friends amongst my professional brethren having called to inquire for me since my accident, and such exaggerated rumours as to its extent having gone abroad, I shall feel much obliged if you will kindly announce, through the *Press*, the real nature of the case.

My left arm was broken by the fall at the insertion of the deltoid muscle, and three ribs broken upon the right side; I also sustained some very severe contusions of the head and body. The position of the fracture has necessitated the most perfect rest in order to facilitate union, but such (I am happy to say) is now progressing favourably under the careful treatment of Mr. Butcher, assisted by my colleague Surgeon Wheeler, and I trust that it may not be very long before I shall be able to resume my professional duties.

For this favourable condition I am also greatly indebted to Dr. Duckett, who, being present at the time, rendered me the most valuable assistance, and prevented all further injury to the limb by temporarily adjusting the bones.

I remain, very faithfully yours,

JOLLIFFE TUFNELL.

DR. M. P. J. and Dr. H. will find the subject referred to in our leader columns. The precedent is undoubtedly a dangerous one, and will, we fear, afford numerous excuses for illicit consultations in the future.

**SANITARY INSTITUTE OF GREAT BRITAIN.**—This (Wednesday) evening, at 8 o'clock, the Chairman of Council, Dr. Richardson, F.R.S., will give a short Address, entitled, "Some brief Suggestions on the best mode of dealing with Small-pox and other infectious Diseases in the Metropolis and other large Towns," to be followed by a discussion.

**ASSOCIATION OF SURGEONS PRACTISING DENTAL SURGERY.**—Wednesday, April 20, at 7.45 p.m., Council.—8.30 p.m., Casual Communications.

**HARVEIAN SOCIETY OF LONDON.**—Thursday, April 21, at 8.30 p.m., "Some Cases of Fibrous Polyp of the Nose and the Operative Treatment of them," by Mr. Henry Morris.—"Difficult Micturition from Prostatic Disease," by Mr. Teevan.

## VACANCIES.

Carrickmacross Union.—Medical Officer. Salary, £120, and £15 as Medical Officer of Health. Election, April 22.  
Hereford General Infirmary. House Surgeon. Salary commencing at £100, with board. Applications to the Secretary before April 20.  
Hospital for Sick Children, Great Ormond Street, London.—Junior Resident Medical Officer. Salary, £50, with board. Applications to the Secretary before April 27.  
Hull and Sulcoates Dispensary.—House Surgeon. Salary, £150. Applications to B. H. Barker, Temple Buildings, Hull, before April 15.  
Midleton Union.—Medical Officer. Salary, £100, and £25 as Medical Officer of Health. Election, April 26.  
Sheffield Public Hospital.—Two Assistant House Surgeons. Salary, £-5 and £50 respectively, with board. Immediate applications to the Hon. Sec.

## APPOINTMENTS.

BARRY, E. F. S., L.K.Q.C.P.I., L.R.C.S.I., Visiting Physician to Kanturk Union Workhouse.  
BATHE, A. J., M.R.C.S.E., L.R.C.P.L., Assistant Medical Officer to the Greenwich Union Infirmary.  
COOMBS, S. W., F.R.C.S., L.R.C.P.Ed., Medical Officer of Health to the Claines Local Board, Worcester.  
CRITCHETT, G. Anderson, M.A., M.R.C.S.E., Ophthalmic Surgeon to St. Mary's Hospital.  
DINWOODIE, W., M.D., M.Ch., Medical Officer for the Kildon District of the Rothbury Union.  
FENN, E. L., M.D., L.R.C.P.L., M.R.C.S.E., Medical Officer for In-patients of the Richmond Hospital.  
GREGGLEY, C., L.F.G.S., Medical Officer for the Yoxall District of the Lichfield Union.  
HARTT, C. H., L.R.C.S.I., L.K.Q.C.P.I., & L.M., Medical Officer to the Central District of Greenwich.  
HAWKINS, H., L.R.C.P.Ed., M.R.C.S.E., Medical Officer for the Fourth District of the Ware Union.  
HEPBURN, A., M.B.C.S.E., House Surgeon and Secretary to the Chelsea, Brompton, and Belgrave Dispensary.  
MALL, H. C., M.B., C.M., Assistant House Surgeon to Leith Hospital.  
SHAW, C. K., L.R.C.P.L., M.R.C.S.E., Medical Officer of Health for the Hastings Urban Sanitary District.  
STUART, S., M.D., L.R.C.S.Ed., Assistant Medical Officer at the Liverpool Workhouse.  
WADD, F. J., M.B., C.M., M.R.C.S.E., Medical Officer for Out-patients of the Richmond Hospital.  
WILSON, Dr., Medical Officer to the Barronstown Dispensary.

## Births.

LITTELJOHN.—April 1, at Hanwell, Middlesex, the wife of Saltern G. Littelljohn, M.B., of a son.

## Marriages.

FARBSTEIN—BERKOWITZ.—April 5, at the Synagogue, Gravesend, Henry Farbstein, M.R.C.S., L.R.C.P., of Hull, to Katherine, eldest daughter of Henry Berkowitz.  
WHERRY—CUST.—April 2, at St. Botolph's, Cambridge, George F. Wherry, F.R.C.S., to Albinia, daughter of R. N. Cust, Esq.

## Deaths.

GIBB.—April 5, at Oxford, Matilda Warburton Gibb, aged 70, widow of Dr. J. R. Gibb, Bengal Army.  
WHITTINGTON.—April 7, at 10 Trebovir Road, Kensington, Jane Carmen, wife of Charles E. Whittington, M.E.C.S., of Tuxford, Notts.

### REMARKS ON DISSOLUTION OF THE NERVOUS SYSTEM AS EXEMPLIFIED BY CERTAIN POST-EPILEPTIC CONDITIONS.

By J. HUGHLINGS JACKSON, M.D., F.R.C.P., F.R.S., Physician to the London Hospital, and to the National Hospital for the Epileptic and Paralysed.

#### INTRODUCTION.

In his "Data of Ethics," p. 61, Herbert Spencer writes, "Every science begins by accumulating observations, and presently generalises these empirically; but only when it reaches the stage at which its empirical generalisations are included in a rational generalisation, does it become developed science. Astronomy has already passed through its successive stages; first collection of facts; then inductions from them; and lastly, deductive interpretations of these, as corollaries from the universal principle of actions among masses in space."

I have long thought that Herbert Spencer's hypothesis of dissolution will enable us to develop a science of disease of the nervous system. Dissolution is the term Spencer uses for the reverse of Evolution. At any rate, there is no harm in trying to see how far the hypothesis of Dissolution will apply to some diseases of the nervous system. I have long ago applied it to the elucidation of cases of aphasia (a), to cases of the ordinary form of hemiplegia and to cases of epileptiform seizures (*Lancet*,

(a) I have in several places (first, *Medical Times and Gazette*, June 23, 1866, quoted Baillarger's important generalisation on some cases of aphasia.

"L'analyse des phénomènes conduit à reconnaître, dans certains cas de ce genre que l'incitation verbale involontaire persiste, mais que l'incitation volontaire est abolie. Quant à la perversion de la faculté du langage caractérisée par la prononciation de mots incohérents, la lésion consiste encore dans la substitution de la parole automatique à l'incitation verbale volontaire." Speaking of a particular case he says, "Il est bien évident qu'il l'incitation motrice volontaire était abolie, et que l'incitation motrice spontanée persistait."

January 18, 1878). I suppose these to be examples of Dissolution beginning in different lower cerebral centres, as insanity is, I suppose, Dissolution beginning in the highest of all centres. I have also long ago applied the hypothesis to the investigation of cases of insanity as in a paper, *Medical Times and Gazette*, July 19, 1873, where, however, I did not use the term Dissolution (see also *Medical Press and Circular*, December 9, 1874, and *London Medical Record*, June 9, 1875).

I have been misunderstood to have put forward the Hypothesis of Dissolution as a basis for classification of cases of Insanity for clinical purposes, and have been asked to go to some lunatic asylum and show how the cases of patients there could be classified under it. That I may in some of my earliest papers on the application of the hypothesis of Dissolution have so carelessly written as to imply that, I dare not deny; I hope I have not. But I have expressly repudiated such application of the hypothesis in several places some years ago. The following is a quotation from a paper in the *Medical Press and Circular*, December 9, 1874. It will be observed that I do not use Arrangement and Classification as synonymous terms:—

"There are very many classifications of Insanity, and this is good evidence of the difficulty in dealing with the complex problems the cases present. For my part, I think we should have arrangements of cases of Insanity for practical purposes, and a Classification on some natural system for the purpose of increasing our knowledge of 'diseases of the mind.' The arrangements, entirely artificial, would only be provisional. They would in asylum practice, start with the very general definition of a lunatic, as a person who requires restraint on account of mental disorder. The arrangements would vary very widely, as the cases were considered from a pathological or therapeutical point of view, or as the patients required different degrees and kinds of supervision. If a certain kind of insanity were often found along with phthisis, this would be a good reason for making a group, 'phthisical insanity,' for treatment, and also for the accumulation of otherwise unrelated facts bearing on pathology. If a patient were suicidal there would be very good

reason for taking that to be the leading feature of his case for certain practical purposes. Then the grouping epileptic (a) insanity is a very useful one. But for increasing our knowledge of insanity and, indirectly, of mental operations in health, these practical arrangements alone will not suffice. We require also a theoretical arrangement, or rather a classification properly so-called—in fact, a classification on a natural system.”

“Cases of insanity should, I think, be classified and investigated on the basis supplied by the doctrine of Evolution of nervous centres. We shall have enormous help in the work Spencer has done in his ‘Psychology.’ We have already explained that we use the term Dissolution as the opposite of Evolution. Insanity is Dissolution, beginning in the highest nervous processes. Moreover, of course, what we call the scientific investigation of insanity is really an experimental investigation of Mind; and in this regard the slightest departures from a person’s standard of mental health are to be studied, and not only the cases of patients who require to be kept in asylums.”

I have written to the same effect in a paper “On Syphilitic Affections of the Nervous System,” *Journal of Mental Science*, July, 1875. To the same effect, too, in a paper “On Affections of Speech from Disease of the Brain” (*Brain*, Vol. I., p. 315, note), wherein I say that classification under the principle of Dissolution is “worthless for immediate practical purposes.” (b)

I should no more urge that cases of insanity in asylums should be classified on the principle of Dissolution than that plants in farms and nursery or market gardens should be classified on the natural system of botanists.

On the other hand, whilst admitting and urging the value of Empirical Arrangements, it does not suffice for a science of Insanity to collect observations of cases of Insanity ordinarily so-called. The observations are necessary materials for empirical generalisations as into varieties of Mania, Melancholia, &c., &c., for purposes of practice. We require for the science of Insanity a rational generalisation, which shall show how Insanities, in the widest sense of that word, including not only cases specially described by alienists, but delirium in acute non-cerebral disease, degrees of drunkenness, and even sleep with dreaming, are related one to another. Dreaming is for such purpose as important as any kind of insanity. More than this, we require a rational generalisation so wide as to show on the physical side relations of diseases of the Mind, which are for physicians nothing but diseases of the highest centres, to all other diseases of the nervous system. We have to find some fundamental principle under which things so superficially different as the diseases empirically named hemiplegia, aphasia, acute mania, chorea, melancholia, permanent dementia, coma, &c., can be methodically classified.

In *Brain*, Vol. I., pp. 308-9, when dealing with aphasia, I have given an enumeration of symptoms in several different diseases of the nervous system, which it is supposed are good examples of Dissolution beginning in different parts of the nervous system.

The following is what is referred to in the text (c) :—

(a) We have, of course, to distinguish betwixt (1) transient mania following an epileptic paroxysm; (2) the more lengthy mental infirmity after a succession of attacks; (3) the persistent deterioration which is a gradual result of seizures often repeated for months and years.

(b) I have written on Dissolution of the Nervous System, *Brit. Med. Jour.*, “Comparative Study of Drunkenness,” May 16 and 23, 1874, and also in the same *Journal*, March 31 and April 7, 1877, “On Unconsciousness and Automatic Actions after Epileptic Fits.” In the fifth volume of Crichton Browne’s “West Riding Asylum Reports, I published a paper on “Temporary Mental Disorders after Epileptic Paroxysms,” in which I relate many cases of post-epileptic actions, but not especially as illustrating Dissolution.

(c) There are certain most general principles which apply, not only to affections of speech, but also to the commonest variety of paralysis, to the simplest of convulsive seizures, and to cases of insanity.

The facts that the speechless patient is frequently reduced to the use only of the most general propositions “yes” or “no,”

Cases of hemiplegia and aphasia are examples of Dissolution beginning in subordinate brain centres. But the cases we deal with in this paper are examples of Dissolution beginning in the highest cerebral centres—cases of Insanity.

Several times it has been admitted, however, that pathological changes are not likely to effect a Dissolution which shall be the exact reverse of Evolution. This was admitted again in a communication to *Brain* (Part X). At a later stage of this work I shall draw particular attention to this.

I may remark now as to the term Dissolution. Strangely, some of my friends suppose it to be one of my own choosing as a name for the reverse of Evolution. It has been used by Herbert Spencer for at least thirteen years (see “First Principles,” second edition, 1867, chapter on Dissolution). The word is said to be not a fit one, and it is urged as an objection to my application of it that it is already in use in another sense. Suppose the word, considering its etymology, to be wrongly applied, or to be more often used in other senses than as the reverse of Evolution of the Nervous System—I really do not see the expediency of adopting another word, or of coining a new one, for the reverse of Nervous Evolution, when Dissolution is already in use for the reverse of Evolution in general. There are objections to the term “Evolution,” but no one now-a-days thinks of displacing that term (see art. “Evolution,” by Sully, “Encyclopædia Brit.”). Fiske (“Cosmic Philosophy,” vol. i., part 2, chapter iii., headed “Evolution and Dissolution,”) writes of the two words:—“Both these terms possess the signal advantage that, while they admit of precise scientific definition, they are at the same time currently used in senses strictly analogous to those in which they are here employed.”

Besides, I do not think my use of the term “Dissolution” can have misled any one, since, unless I am very much mistaken, I have always, when using it, declared it to stand for the reverse of Evolution. In earlier papers I used the term “Reduced to a More Automatic Condition.”

The main part of what I may be able to show in this work consists in illustrating Spencer’s doctrines of Nervous Evolution, by the reverse process of Nervous Dissolution, as this is effected by pathological processes, and especially by excessive discharges beginning in parts of the highest cerebral centres—that is to say, by cases of Epilepsy Proper. Readers will not, of course, judge Spencer’s doctrines from my application of them. I should take it as a great calamity were any crudities of mine to be attributed to this distinguished thinker.

or both; that he may be unable to say “no” when told, although he says it readily in reply to questions requiring dissent; that he may be able ordinarily to put out his tongue well, as for example to catch a stray crumb, and yet unable to put it out when he tries, after being asked to do so; that he loses intellectual language and not emotional language; that although he does not speak, he understands what we say to him; and many other facts of the same order, illustrate exactly the same principle as do such facts from other cases of disease of the nervous system as—that in hemiplegia the arm suffers more than the leg; that most convulsions beginning unilaterally begin in the index finger and thumb; that in cases of post-epileptic insanity there are degrees of temporary reduction from the least towards the most “organised actions,” degrees proportional to the severity of the discharge in the paroxysm, or rather to the amount of exhaustion of the highest centres produced by the discharge causing the paroxysm. In all these cases—except in the instance of convulsion, which, however, illustrates the principle in another way—there are, negatively, degrees of loss of the most voluntary processes with, positively, conservation of the next most voluntary or next more automatic; otherwise put, there are degrees of loss of the latest acquisitions with conservation of the earlier, especially of the inherited, acquisitions; speaking of the physical side, there are degrees of loss of function of the least organised nervous arrangements with conservation of function of the more organised. *There is in each reduction to a more automatic condition: in each there is Dissolution, using this term as Spencer does, as the opposite of Evolution.*

I have further obligations to acknowledge. We must remember that Laycock, about forty years ago, made the very fruitful generalisation that the cerebral centres are, like all lower centres, "reflex." The more recent doctrines of Evolution of necessity imply that all nervous centres, even the highest—the substrata of consciousness—are sensori-motor. Some years ago my colleague, Dr. Gowers, drew my attention to remarks by Sir Charles Bell, to the effect that, in debility, the voluntary fails before the automatic. I quoted Bell's remarks, *Lancet*, Feb. 15, 1873. I have already acknowledged my obligation to Baillarger.

I adopt the hypothesis by Todd and Alexander Robertson that temporary local paralysis after epileptiform seizures is a result of central exhaustion consequent on excessive nervous discharges during the paroxysm, and apply the hypothesis in the explanation of the conditions of patients after seizures of epilepsy proper. I adopt the hypothesis of Laycock and Monro that the symptomatic condition in insanity is duplex—that there is a negative and positive element. I also make great use of an hypothesis of Anstie and Dickson Thompson, which may be briefly stated as amounting to this—that positive mental symptoms are indirectly caused by disease, are owing (to use Dickson Thompson's phrase) "to loss of control." This principle has been stated also by Rutherford and by Lauder Brunton.

The principle that we get over action of lower centres by the mere removal of the influence of the higher centres was distinctly formulated by Anstie many years ago. Thus, speaking of the effects of opium, he wrote:—"The apparent exaltation of certain faculties should be ascribed rather to the removal of controlling influences than to the positive stimulation of the faculties themselves, or of the physical machinery by which they work."—"Stimulants and Narcotics," p. 80.) Dickson Thompson stated the same principle as to delirium, and also as to the epileptic paroxysm. In his application of it to the epileptic paroxysm I do not follow him, although I do with regard to post-epileptic mania and other positive conditions after epileptic attack. The very same principle was applied by Symonds in the explanation of dreaming which is physiological insanity—is a normal Dissolution. In his article on "Sleep and Dreams" (1850, although, I believe, not published until 1871), Dr. Symonds writes:—"I am inclined to think that by reason of the diminished action in the part of the brain connected with sensation there may sometimes be increased action in that connected with the revival of past impressions, in correspondence with a law constantly operating in the human economy, that diminished action in one part causes exalted action in another; but this view is hypothetical."

The general subject of epileptic insanity has long been clinically handled by both alienist and general physicians, especially by Morel, Falret, Trouseau, Tuke and Bucknill, Nicolson, and Howden. Dr. Howden's paper, "The Religious Sentiment in Epileptics," *Journ. Medical Science*, Jan., 1873, is a highly original article of extreme value. Dr. Thorne Thorne, in the St. Bartholomew's Hospital Reports, has recorded a case of post-epileptic automatism of far greater medico-legal value than a score of cases of ordinary epileptic mania. Perhaps the most valuable of all cases of the kind is one recorded by Weir Mitchell in a paper on the "Use of Nitrite of Amyl." Everything this physician writes is of the best. I regret to say that the reprint of his paper does not tell us where it was originally published. Dr. Hack Tuke's papers on "Artificial Insanity" deserve very careful study.

I must also mention my indebtedness to Symonds' articles on "Dreaming," to a chapter on the same subject, by Griesenger. Also to Macnish's articles on Drunkenness and Dreaming. I would particularly draw the reader's attention to Spencer's chapters in his "Principle of Sociology" on Primitive Man, Intellectual and Emotional, and to his statements in other parts of that work

on Dreams. In the third volume of Spencer's essays is an article most important to students of "Diseases of the Mind," entitled the "Comparative Psychology of Man."

So then, whilst quite willing to take the full responsibility of what I say, I am also ready to declare that the previous workers mentioned have rendered it difficult for me to put forward anything more than a sort of harmonisation of their doctrines. For the use I make of their work, they are not answerable. I make these remarks because handling the subject in an unusual way, and often using different terms from those generally used, the reader might suppose there to be great novelty in places where there is really none. We must remember, too, that many doctrines were stated years ago in principle which were then novel and much disputed, but are now so generally accepted that we are in danger of ceasing to think of the very early propounders of those doctrines. The credit is sometimes given to the popularisers of the doctrines, especially if he fits them in with new researches. By putting old doctrines in new ways, and using, in their exposition, more recent terms, we may deceive ourselves into the belief that we are saying something fundamentally original. The principle of duality of mental states (negative and positive) which, I have to insist on at length, is essentially a direct reproduction of what Laycock said about thirty years ago. As Dr. Carpenter tells us, "The extension of the doctrine of reflex action to the brain, was first advocated by Dr. Laycock in 1844. In what Laycock wrote on Odyle Mesmerism, and Electro-Biology in 1851, is embodied a principle which is, I believe, true of such cases as uproariousness after intracranial hæmorrhage, boisterous conduct in drunkenness, and of epileptic mania. Borrowing Laycock's words, we may say of these cases—"One great fact proper to all is that the action of the Will and of Consciousness is suspended, and the encephalic ganglia placed in the condition of the true spinal or reflex system." Here are two elements—the negative and positive. If attention be too much taken up with the words "Odyle," "Mesmerism," and "Electro-biology," the reader may overlook the fact that however nonsensical be the doctrines those words cover in the mind of the populace, the sentence quoted shows a broad principle of great value in the investigation and classification of disease; that there is a reduction to a more automatic condition, or, in other words, there is a duplex condition, negative and positive. The reader must bear in mind that the above is what Laycock wrote in 1851. He would, doubtless, later have used different expressions, but the principle is in the sentences quoted, whatever we may say about the terms used.

I may take this opportunity of quoting another writer on "Negative and Positive Conditions in Insanity." Dr. Henry Munro long ago stated his opinion that there is in insanity a negative and a positive condition. The following quotation is the "Syllabus of the Argument" of his work, "Remarks on Insanity," 1851. "The theory laid down in these remarks is—that insanity is a disease of loss of nervous tone; that this loss of nervous tone is caused by a premature and abnormal exhaustibility of the vital powers of the sensorium; that this infirmity is essentially a local one, though torpor of the general, physical, and vital powers assists it; and that its origin is to be esteemed constitutional, congenital, and frequently hereditary."

"As a part of, and arising from this theory, the coincident excesses and deficiencies of mental phenomena manifested by the insane, are attributed to the coincident existence (in different parts of the sensorium) of those two stages of loss of nervous tone, *irritable excess of action* and *paralysis*. This view of the case renders it unnecessary to believe that the violent excesses of the insane must arise from a too sthenic condition of the system—a doctrine which experience so much contradicts, but which the want of experience so often propagates."

I mention that the authors above quoted are not responsible for what I borrow from them, or rather for my

application of what is borrowed, since I fear some of them would not admit that their doctrines are properly represented, or they might see them combined with others in ways they would not approve. Hence it is not inconsistent to acknowledge that much of what I have to put forward has been said in principle before, and yet to take full responsibility, because I am saying it in a different way. I make these statements voluntarily; no one has advanced any claim to priority on the points I mention.

The foregoing must not be taken as an admission that I have not worked quite independently at most parts of the subject.

(To be continued.)

**ON TEMPERATURE AND ITS RELATION TO MORTALITY: AN ILLUSTRATION OF THE APPLICATION OF THE NUMERICAL METHOD TO THE DISCOVERY OF TRUTH.**

By WILLIAM A. GUY, M.B., Cantab., F.R.S.,  
One of the Honorary Presidents of the Statistical Society.  
(Continued from page 311.)

UP to this time Dr. Guy's paper had been dealing with the mixed populations of several countries and places, and with men, women, and children exposed in every possible way and degree to the current atmospheric influences. He now proposes to inquire whether the same relation of temperature to mortality obtains among the mixed class of persons whose lives have been insured, after the usual medical examination, and who, one with another, suffer less by atmospheric exposure, and the labours and privations which poverty (the lot of the majority) entails than their poorer neighbours and the mixed communities to which they belong. Thanks to a conversation with his friend, Mr. George Humphreys, secretary and actuary to the Eagle Insurance Office, Dr. Guy was made aware of the publication year by year of the experience of the well-known German insurance office at Gotha to the half century ending 1878. (a) The tables present the deaths and causes of death of 22,014 persons (of course, chiefly males) from twenty-three leading causes, more or less definite, namely:—

1. Pulmonary consumption, pulmonary catarrh and bronchitis, pulmonary apoplexy, and inflammatory diseases of the chest, forming together a well-defined group of diseases of the lungs.
2. Old age.
3. Typhus, rheumatism of the joints, inflammation of the brain and mental diseases—all of which causes of death in common with 1 and 2 fall under the same category. The mortality varies inversely as the temperature.
4. Asiatic cholera, inflammation of the bowels, and chronic disease of the liver—these diseases cause a mortality varying directly as the temperature.
5. Cerebral apoplexy, chronic diseases of the brain and spinal cord, cancer, and diabetes, which give rise to a mortality in which the temperate months of the spring and autumn take the lead, and are followed in order by the cold and hot months.
6. Suicide and chronic disease of the heart, of which the victims are most numerous in the temperate months, the hot and cold months following in their order.
7. Bright's disease, and infectious disorders, other than cholera and fever, in which the cold months are most fatal, and the temperate months least so.
8. A mixed group of accidents, external injuries, and tumours which have their maximum mortality in the colder months, and their minimum in the temperate.

(a) Mittheilungen aus der Geschäfts- und Sterblichkeits-Statistik der Lebensversicherungsbank für Deutschland zu Gotha, für die fünfzig Jahre von 1829 bis 1878. Herausgegeben von Dr. A. Emminghaus (1880).

9. And lastly, a miscellaneous group of diseases and causes of death, in which the hot and temperate months exhibit a mortality equally in excess of the deaths in the cold months.

A summary is then given of the results of the fifty years' experience of this, the leading insurance office of Germany.

The aggregate of the 22,014 deaths are grouped as follows:—

Four cold months, 7,703; four temperate months, 7,525; four hot months, 6,786; which figures yield the percentage proportions—35, 34, and 31.

The four affections of the lungs, consumption, bronchitis, pulmonary apoplexy, and pneumonia, if grouped under the one heading—diseases of the lungs—present the following figures:—

Four cold months, 2,339; four temperate months, 2,148; four hot months, 1,524; or per cent., 39, 35, and 26.

The details are as follows:—

	Four Cold Months.	Four Temperate Months.	Four Hot Months.
	Per cent.	Per cent.	Per cent.
Consumption.....	36	34	30
Bronchitis, &c.....	39	33	28
Pulmonary apoplexy.	41	39	20
Pneumonia.....	42	37	21

2. Old age. Under this head the figures for the cold and temperate months show a near approach to equality. They are respectively, 580 and 560; and the approximate percentages are:—

Four cold months, 36; four temperate months, 35; four hot months, 28.

3. The mixed group (typhus, rheumatism of the joints, inflammation of the brain, and mental diseases), which share with lung diseases and old age a death-rate varying inversely as the temperature, yield the following figures:—

Four cold months, 37; four temperate months, 35; four hot months, 28.

4. The three diseases which exhibit a death-rate ranging directly as the temperature (Asiatic cholera, inflammation of the bowels, and chronic diseases of the liver) present the following percentages:—

Four cold months, 25; four temperate, 32; four hot, 43.

These four groups are those which yield us the most definite results.

If the relation of temperature to mortality be really so direct and considerable as all Dr. Guy's inquiries up to this point so clearly indicate, additional evidence of that relation must be obtainable in the shape of a comparison of the death-rate in two years or seasons, in one of which the thermometer indicates a much lower temperature than the other. Such a comparison Heberden himself makes, in a table at p. 52 of his work. This instructive table Dr. Guy gives in a somewhat altered and more condensed form:—

	Deaths above 60.		Difference of Temperature.	
	Warmer Year, 1796.	Colder Year, 1795.	Noon.	Noon.
1st week	35	51	15	17
2nd "	37	139	15	17
3rd "	29	145	24	23
4th "	20	143	28	25
5th "	32	239	16	12

This comparison, if it were to stand alone, would be conclusive as to the close relation that exists between temperature and mortality, and especially in aged persons.

It illustrates the power of cold in raising the death-rate of the aged, and also of its continued operation through a series of weeks. The first week of the series exhibits a fall of 15° and 15°, and a death-rate augmented from 35 to 51; but the second week, with a like fall of temperature, shows a nearly fourfold increase. The cold continues and increases from 15 or 17 to the much higher figures of the table; and the further fall, coupled with the longer continuance of cold, raises the mortality fivefold, then sevenfold. The temperature rises several degrees in both the contrasted weeks; but the deaths show a further increase, being more than sevenfold. We have now become familiar with this distinctive effect of cold; but this instance (now eighty years old) is well worth recording.

In an appendix to his paper, Dr. Guy justifies by figures the statement of Celsus, respecting the deadly character of the Roman autumn.

The Roman autumn, condemned by Celsus as "*longe periculosissimus*," began on the 6th August, and may be said to have comprised the three months of August, September, and October. The remainder of the year must therefore have been distributed thus:—Winter—November, December, January; spring—February, March, April; summer—May, June, July.

Now, if we arrange the deaths for Marseilles and Montpellier, as they are stated by Heberden at p. 49, we obtain the following results:—

Seasons.	Marseilles.	Montpellier.
Spring.....	4,982	2,104
Winter .....	5,225	2,843
Summer .....	4,850	2,480
Autumn .....	5,242	3,307

It would appear, then, that in the last century, these two cities, which may be taken to represent approximately the climate about which Celsus wrote, display a striking contrast between a spring marked by a low mortality and an autumn extremely fatal to life. In this they resemble the Rome of Celsus. But in Marseilles the summer is less fatal than the spring; while in Montpellier, summer takes the place of winter, as coming next in order of healthiness to spring.

CLINICAL LECTURE ON HERPES.

By J. MAGEE FINNEY, M.D., F.K.Q.C.P.I.,

Visiting Clinical Physician and Dermatologist to the City of Dublin Hospital.

(Continued from page 223.)

GENTLEMEN.—Herpes zoster, zona, or shingles, is peculiarly of neurotic origin, and the cutaneous eruption of the vesicles is but the exponent of the nerve irritation which produces it.

The intelligent appreciation of this, now universally accepted, etiology will explain the occurrence of herpes, the course and direction of the eruption, and its concomitant neuralgic symptoms.

The intimate relation of the ganglionic vasomotor system with that of motion and sensation has much to say to the development of this form of herpes, but unfortunately the advances to unravel this union have not been as yet very successful in explaining the conditions under which herpes will make its appearance in some individuals, while in others, under seemingly similar circumstances, no herpetic complication will arise.

To explain this seeming caprice of Nature is as difficult, nay, as impossible, as to say why, when exposed to a similar exciting cause of disease, such as a chill, one

group of individuals will be affected with bronchitis, another with nephritis, another with serous inflammations, and so on.

Without, therefore, endeavouring to explain what still lies shrouded in the misty land of surmise and theory, it is sufficient for you to remember that the origin of herpes zoster is due to nerve irritation and inflammation; that the constant pathological changes have been found to be a neuritis of the affected nerve branches, with an induration and increase in size of the ganglia of the sympathetic connected with their roots. In some instances the nerve inflammation may be induced by direct pressure of a tumour, as, for instance, that of an aneurism of the thoracic aorta, causing herpes intercostalis, or may be the result of injury to the nerve; but in the majority of instances of zona it is idiopathic, and the exciting cause must be looked for among those which give rise to neuralgia generally, of which unfortunately very few are traceable. The gouty habit of body, mental worry, exposure to sudden cold on superficial nerves while the nervous power is exhausted may be enumerated, as some of the factors.

There are certain peculiarities about Zoster which you should bear in mind.

1st. The disease, as a rule, attacks an individual but once in his life. I say as a rule, for there are instances recorded where more than once—even up to five times (Kaposi)—the disease has been noted to recur.

2nd. It is unsymmetrical, being confined to one side of the trunk or extremities. To this very few exceptions have been recorded, and even where both sides of the trunk have been affected with herpes at the same time, the disease will not be at exactly the same level. Very commonly, however, you will find some clusters of vesicles transgress the exact middle line.

3rd. The disease runs alongs the course of the sensory cutaneous nerves, the groups of vesicles being thickest over the spots where the nerve gives most branches to the skin. Now on the trunk, when the branches of the dorsal and upper lumbar nerves are the seat of the disease, the herpes following these nerves will involve one half of the body, as by a girdle, and hence it is called Zona or Zoster; but remember that as the nerves pass obliquely downwards from behind forwards, the vesicles in front over the sternum or rectus abdominis will be on a lower level than those over or near the vertebral spines.

Again, when the nerves of the arm or thigh be those engaged, the herpes will follow their course in the long axis of the limb, and will not surround it. In like manner when the upper branches of the fifth nerve be its seat, it will travel from the supra-orbital notch up over the forehead into the scalp.

4th. Although it is equally common on either side of the body, it is rarely seen on the forearm and hand; and it has never been met with on the leg or foot. It occurs most frequently in certain situations, so that they may be termed its seats of preference, namely, the branches of the intercostal and lumbar nerves. The correctness of this observation you have often noted, for although we have seen the disease in every possible place, the greater number have been in these localities. Next in frequency the branches of the supra-orbital nerve may be enumerated, although the experience of our hospital practice would give the musculo-spiral third place.

5th. The attack is usually ushered in by what may be termed neuralgic symptoms—often very severe, following the course of the nerve affected. At times the sensations are those of a burning pain; at others, of a sharp stinging character, so that when the intercostal nerves be those affected, it may closely resemble the pain accompanying inflammation of the pleura. Those symptoms may be of short duration, or may last three or four days, before any cutaneous eruption is evident.

And here I may say that on more than one occasion I have been able to establish a diagnosis by a careful ocular examination of the affected parts; and I would

most strongly advise you to adopt a similar precaution in your private practice, lest you may treat for pleurisy or intercostal rheumatism a case of herpes zoster.

Sooner or later patches of red skin are noticeable over the painful parts, and groups of papulo-vesicles, becoming vesicles and then pustules, make their appearance. The disease is then, in short, a neurotic affection, preceded by certain neuralgic symptoms—at times very severe. These are shortly followed by erythematous patches in the course of the cutaneous distribution of the affected nerve or nerves. On these red patches appear a number of vesicles—sometimes minute, sometimes large, and either separate or confluent—which, when fully developed, become converted into pustules, and end in drying up into scabs, and often leaving after them nasty ulcers and permanent white scars.

The course of the attack is usually completed in ten or twelve days. It may, however, abort in some spots, so that we have often noticed some patches ending in small pimples or vesicles, others going on to pustulation and scabbing, and even in cases where vesiculation is the rule, it is very unequally distributed.

If you recollect the various symptoms we have noticed in patients suffering from herpes zoster, you must have been struck by the difference with which the cases ended. The majority of the patients were young, and they seemed to suffer very little discomfort, except from the healing of the small ulcers, while those who were past middle life, not only at the onset, but also after all the eruptions had disappeared, suffered so acutely from neuralgic pains that hypodermic injections of morphia were not unfrequently required. This is a point to which I wish to call your particular attention, that in elderly people herpes zoster is a very serious disease on account of the immediate sufferings it produces, and of the obstinate neuralgia which may follow the eruption for several months. Some ten years ago I remember one such case in an elderly lady, a member of a nobleman's family, where I had the advantage of other advice. I regret to say that, owing to want of sleep and the exhaustion induced in a feeble frame from continued pain, the patient succumbed five weeks after the eruption was healed.

The following cases, taken from our case-books, will further elucidate the subject, and sufficiently recall to your mind the treatment adopted:—

**CASE I.—Herpes Zoster, Cervico-Occipital.**—Eliza Gaffney, æt. 50, presented herself at the Skin Dispensary, Feb. 23rd, 1878, with herpes zoster of the right side of the neck and occiput, of 10 days' standing. The disease followed closely the direction of the *occipitalis major and minor* nerve. She stated that for 3 days she suffered great pain in the back of the neck and head, and that then a number of spots (vesicles) appeared in the posterior triangle of the neck, extending up to the back of the external ear, and to some distance on the hairy scalp, and that with the appearance of the rash the pain left her; that she had never felt strong since then, and that she has had very little sleep. She looked haggard and worn, the eruption was pustular in several patches, some of it already drying up. As the hairy scalp was involved almost up to the vertex, and the disease well advanced, our treatment consisted in the application of simple ointment, and the internal application of sulph. quinzæ in tinct. ferri perchloridi, and infus. calumbæ three times a day. Under this she rapidly recovered, and had no subsequent neuralgic symptoms.

**CASE II.—Herpes Zoster, Left Lumbo-Inguinal.**—Robert Clinch, æt. 18, a gas-worker, was seen at the Dispensary on July 19th, 1879. Seven days ago he had pain over the left anterior superior spinous process of the ileum. He thought he must have hurt himself. However, in two or three days he noticed various red spots about the hip. The disease was strictly limited, in the middle line behind to the spines of the third and fourth lumbar vertebrae, where a considerably-sized patch of confluent vesiculo-pustules were seen; it then followed accurately the course and distribution of the *ilio-hypogastric, ilio-inguinal*, and *external cutaneous* nerves, and the *crural* branch of the

*genito-crural* nerve. The patches were large over the outer surface of the ilium, where the iliac branches pass out to supply the skin of that region; they were smaller, less pustular, and more scattered over the hypogastrium; while over Scarpa's space and the upper third of the vastus externus, several large clusters were standing on a reddened base.

This case exemplified both the peculiarly accurate way in which the disease follows the cutaneous distribution of sensory nerves, and the fact that the eruption neither makes its appearance all at once, but in crops over different parts of the nerve at different intervals, nor is it equally developed over the affected parts. In this boy the patches varied—some were large confluent pustules, others separate vesicles, and others were aborted erythematous papules. As is very usually the case in herpes, this patient presented an anæmic appearance. Ferruginous preparations being indicated, I gave him the citrate of quinine and iron. No other remedy in my experience is so useful in preventing the neuralgic sequelæ, and in restoring the health. At times I vary it with quinine, tinct. perchlor. ferri, and chlorate of potash; but, as a rule, the former combination agrees best with the stomach, and has the advantage of being combinable with alkalies. The local treatment consisted in simply keeping the parts thickly dusted with the following powder, and covered with a large sheet of wadding, finely powdered starch, oxide of zinc, of each two drachms, with five grains of camphor.

**CASE III.—Right Lumbo-Hypogastric et Inguinal.**—Helen Lyons, æt. 17, dressmaker, attended the Dispensary in Feb., 1880, with herpes following almost exactly the same course as Case 2. It was, however, a very much more severe attack as the patches of vesicles were almost continuous; the disease also transgressed the middle line behind by an inch or two, and extended into the mons veneris, and more over the adductor muscles than the outer side of the thigh. This patient, who looked sick and exhausted, had had very acute pain in the side for 4 days before any appearance of the eruption. It then came out in a few spots over the back at first, and then gradually spread during five days until it presented the aggravated characters it had when I saw it. She had not slept for several nights, and was low, depressed, and nervous, with complete loss of appetite.

The treatment was much the same as in Case 2, with the addition of sleeping draughts, and the application of collodion flexile to some of the patches which were in their early or clear-vesicular stage. The attack lasted over a fortnight, but though it was one of the worst cases with which we have met at the hospital, a good recovery was made, and not more than one or two scars were left.

**CASE IV.—Herpes Brachialis.**—Peter Kavanagh, æt. 12, attended the Dispensary for Skin Diseases last August. He complained of pain in the right arm for about a week, but it was by no means severe, nor was he sick in any way. Four days after he first complained, three red spots covered with vesicles were noticed. The disease was limited to the deltoid, the outer half of the biceps and the bend of the elbow, and followed closely the course of the ascending branches of the circumflex nerve, and the cutaneous branches of that and of the musculo-spinal nerve as far as the bend of the elbow, where the largest patch of herpes to the size of half-a-crown existed. The only treatment in this case was the application of flexible collodion.

**CASE V.—Herpes Thoracico-Brachialis of the Right Side.**—George Burke, æt. 6, was admitted to the children's ward in January last, on the recommendation of my colleague, Mr. Croly. The child had been ill five or six days, and the eruption had almost completely come out. There was no history of any pain or illness preceding the rash. The eruption was copious, and exhibited every variety, from the erythema to confluent pustulation. Some of the vesicles aborted naturally, and others were checked by the generous application of flexible collodion. As some of the vesicles had been ruptured by being

rubbed, these parts were kept covered by strips of old linen soaked in linimentum calcei, and as the child was ill-nourished, cod-liver oil and syr. iod. ferri were given along with a generous diet.

The chief interest lay in the course and distribution of the eruption, and you remember how accurately the clusters of vesicles mapped out the sensory filaments of the circumflex humeri, the intercostal humeri, and the small internal cutaneous (Wrisberg) nerves of the right side.

Looking at the patient in front, a few clusters are visible over the lower edge of the lesser pectoral muscle, and others in the axilla, which are confluent in patches of half-a-crown. Other patches are seen on the inner surface of biceps, and a large cluster in front of and above the internal condyle. On looking at it behind, or on raising up the arm, much more extensive eruption is seen. 1. A few spots near the 1st and 2nd dorsal spines. 2. Others over the teres minor muscle. 3. Over the back part of deltoid. 4. Several patches along the inner side of long head of triceps. 5. A very large cluster above the internal condyle.

The nerves involved were evidently traceable through the brachial plexus to the 7th and 8th cervical, and 1st dorsal nerves, and the distribution of the herpetic eruption thus pathologically mapped out the nerves, from which the parts indicated received their sensory supply.

It is unnecessary to multiply examples. SuffICIENT has been said to point out peculiarities of this interesting disease. As to the diagnosis of herpes, I feel sure any of you who have noted the cases we have examined together, could have no difficulty in arriving at an accurate conclusion as to its non-identity with *catarrhalis*, and in discriminating between it and any other similar affection.

In conclusion, in treating herpes, use your best skill to allay the inflammation of the skin by cooling, soothing applications, and avoid anything which may possibly irritate, and thus leave a scar. When sleep is broken use hypnotics. Should the pain be very severe you may give hypodermic injections of morphia, and apply a cooling sedative lotion (consisting of liq. atropiæ, liq. plumbi subacet., aa ʒij.; glycerine, ʒij.; aqua rosæ, ʒvi.), on lint, and cover it with gutta-percha tissue. For the subsequent, and often accompanying, neuralgia, the preparations of quinine, either alone or in combination with arsenic or iron, answer best.

## Translations.

### ON SIMULATED INSANITY. (a)

By Dr. SNELL, of Hildesheim.

TWENTY-FOUR years ago I published a small paper in the *Allg. Zeitschrift. f. Psych.*, (vol. 13, No. 1) on simulated insanity, describing three cases of simulation. The first case occurred in a convict, who had excited the suspicion that he was insane by singing, dancing, and incoherent talk. On closer examination of his condition he betrayed the attempted deception by his utterly nonsensical statements. For example, he maintained that the week consists of ten days. He would not recognise a single individual of those around him, though he had known them intimately for several years, and the like. But after a few days, when he found that his behaviour obtained no credit, he gave up the imposture.

The second case occurred in a man, æt. 27, who had been accused of perjury, and who was remanded. After a sojourn in prison of two months pending investigation, he suddenly exhibited an entire alteration in his mode of conduct. He jumped about in his cell, and screamed "fire," while his behaviour and speech were seemingly quite distracted. Removed to an asylum, he assumed an immovable attitude, and stared straight before him. When he was invited to

dance, he rose at once, danced round several times in a circle, and then sat down again quietly. Asked his name, he called himself Anton U—, whereas his real name was Peter U—. When he was asked to count he did so in the following mode, 1, 3, 5, 7, 10, &c. He maintained that twice 3 was 7. In reading as well as writing he left out single letters. He did not relinquish the simulation till he was condemned by the court to several years' imprisonment.

The third case occurred in an elderly woman who, in order to invalidate a sale that she regretted, pretended to be imbecile, and sought to prove this by a multitude of depositions. When I got this woman to count, she did so in a quite similar style to the malingering described in the second case, thus—1, 2, 4, 6, &c. She maintained that twice 2 was 6, and declared that she had four fingers on each hand. She affected neither to know the number nor the names of her own children, for she gave a false number and false names. I pronounced this woman's behaviour to be simulation, and singularly enough about the same time an information was lodged in court to the effect that she had suborned false witnesses. It was proved that by bribery she had induced twelve witnesses to perjure themselves. All concerned were condemned to imprisonment.

I venture to add to these three cases of simulated insanity two others, perfectly similar to them, which have come under my notice within the past few years.

On the 26th October, 1879, Christian F., a prisoner detained pending investigations, was brought to the asylum at Hildesheim in order that his mental condition might be decided upon.

Christian F., æt. 29, factory worker, married, was brought under arrest on account of indecent assaults upon children. He had spent several weeks in prison pending investigation without offering any appearance of bodily or mental ailment, when suddenly, fourteen days before his transfer to the asylum, he began to conduct himself in the most extraordinary manner. He made thoroughly disconnected replies, assumed extraordinary attitudes, maintained that he could not sleep, and had apparently become quite a changed man. When he was admitted into the institution his condition was as follows:—A strongly-built man, with intelligent countenance, and presenting as far as the bodily organs go not the least appearance of ill-health. His attitude and movements were in the highest degree remarkable. He stood quite still as if seized with catalepsy. He stared about him as though astonished, and sometimes shook his head. When one pushed against him quietly he moved backwards, or turned round bodily in a circle. On being questioned, he first stared at the person speaking to him, and then answered quite from the point, and in a hesitating voice. For example, to the question "how old are you?" he replied, "100 kilometres." He often merely repeated the words of the questioner. In the evening he lay down in a posture the reverse of the usual one, with his head to the foot of the bed and his feet on the pillow. Next day he replied freely to all questions that were put to him. Being asked how many ears he had, he answered, without hesitation, "5 ears." He had also, he maintained, "5 eyes," and "5 pounds of nose." To the question, how many fingers have you on both hands, he replied "20 fingers." He multiplied thus—"twice 4 are 6, and twice 5 are 8." When he was shown a gold watch and asked of what metal it was he answered "iron." He called a large door-key a watch-key, and a mark piece a dollar. When he was requested to sign his name he wrote a confused and jumbled medley of strokes. In reading, he stumbled over the letters like a little child, and left some letters out entirely. All this conduct he only stuck to for a few days. When he saw that the other patients around him behaved quite differently, and laughed at him for his silly answers, and when it became evident to him that he obtained no credence, he gave up the attempt at deception, and after five or six days conducted himself like every other rational being. He only persisted in one imposture, for he maintained that he knew nothing of the crime that was laid to his charge.

After he had been under observation in the institution for eleven days he was brought back to prison as not being insane. In the further course of his trial he behaved quite reasonably, and made no other attempt to simulate insanity. He was condemned to several years' penal servitude.

In the year 1875, the subjoined case of simulation was observed in the institution at Hildesheim:—

(a) Translated from *Allgemeine Zeitschrift für Psychiatrie* (Band 87, Heft. iii.) By Conolly Norman, F.R.C.S.I., Assistant Resident Medical Superintendent, Monaghan District Asylum.

In the October of the year named, a convict named August Kl., was transferred to the institution for the decision of his mental condition. He was a man, *æt.* 57, had been a hair-dresser in a little town, and had been condemned to six years' penal servitude for perjury. He was described as a frivolous-minded man, addicted to sexual excesses. In October, 1874, he commenced his period of punishment in the convict prison, Lüneberg. Nothing unusual was noticed about him, but he was said to be careless and lazy in performing his appointed tasks. Since May, 1875, his behaviour was remarkable. He was often restless at night, repeatedly undressed himself during the day, and tore up his clothes. Sometimes he barked like a dog, and once smashed the window panes. He often complained of pain in the head, and maintained that he had "monks" there. He once told a story of a visit which the Emperor and Prince Bismark had paid him. At the same time he generally exhibited a limping gait, and a trembling of the hands and legs. These and other striking symptoms caused the prison authorities to transfer him to the asylum at Hildesheim for observation.

August Kl. was of low size, and somewhat feeble muscular development, but on closer examination exhibited no morbid peculiarities. He inclined generally towards the right side in standing and walking, and the extremities were frequently tremulous. On being asked as to his health, he replied that he had "mice" in his head which occasioned him much pain. Questioned about his name and his business, he declared that he knew nothing about all that. He was then questioned as to his comprehension of the relations of numbers. He counted in the following way—1, 2, 3, 6, 9, 11, 13, &c. He multiplied thus: 3 times 3 are 6, twice 3 are 9, 4 times 4 are 7. He maintained that the half of 10 was 3, but how much twice 10 makes he did not know. He was then requested to read the title-page of a vol. of Schiller's work, running thus: "Friedrich von Schiller's sämmtliche Werke." He read in this manner: "Frietag auf Sonnabend sämmtlich ausmarschirt." He was now asked to write. Being required to set down the numerals in order, he first made a row of strokes, and when that was declared insufficient, wrote 1, 2, 3, 5, 7. Being questioned, he stated that these figures signified 1, 2, 3, 6, 9. The individual numerals were ill-formed and twisted in an exaggerated way, that made the intention to deceive quite obvious. His name, "Klöpfer," he wrote "Köpfer," and in this word likewise there was an affected twisting and distortion of the letters. When pieces of money were put before him he uniformly gave them false names. When a watch was held before him, the hands of which stood at 10.30, he maintained the hour it showed was 1 o'clock. He even named objects wrongly, for instance, he called a lead pencil a stick, and a cigar case a pocket book. After this kind of simulation had been manifested, the subject of the deceit was earnestly exhorted to give up his attempt and employ himself usefully. He followed this counsel, but only very gradually, slowly relinquishing one pretence after another. He took to walking with a firm step again, was no longer tremulous, and declared that his memory was certainly getting better every day, for he could now once more read, write, and cipher, and was also again recollecting his personal affairs. He persisted for some time longer that he had mice in his head. At length, after a period of four weeks he resumed the *role* of a perfectly rational creature. He now endeavoured to win the favour of the physicians and officials of the institution by a friendly and polite demeanour; he read prayer books ostentatiously, and diligently visited the church.

After some months he was brought back to prison, and we are not aware that he has again aroused suspicion by his behaviour in any way.

When the above five cases of simulated mental disease are compared they display a remarkable agreement. In each of these cases an endeavour was made to represent a complete forgetfulness of the most simple circumstances and relations of personal life. The ideas of number, to which a man is trained from infancy, appeared suddenly obliterated, and with them a series of other ideas such as are most closely combined with human consciousness. It is obvious that anyone who has made the forms of psychical disease the object of observation, even in a limited degree, cannot accept so sudden a collapse of the mental individuality as a real symptom of disease, or as anything but simulation. In genuine insanity, such a combination of appearances as were observed in the above cases can in no wise exist. A more or less complete suspension of all

the mental functions is met with in those cases of melancholia which we call stupor. In mania the excitement and confusion not unfrequently reach such a height that the answer no longer corresponds to the question that is put, and the patient may even utter mere incoherent words and cries. In imbecility, whether congenital or acquired, the indications of mind are often shadowy enough. Patients of this sort may also exhibit a lack of the conception of numbers. Thus, for instance, there is an idiot in the asylum at Hildesheim who, in replying to a question dealing with the relations of numbers makes the most incorrect answers without reflection or consideration. When he is asked how much is twice two, he answers unhesitatingly, "20," or "10," or any other number. He has not the smallest conception of numbers. Having heard the names of the numerals he reproduces these quite mechanically, and quite without any knowledge of their significance. A female patient in Hildesheim, suffering from paralysis, has forgotten the name of her husband; and a male patient, affected with senile imbecility, does not know the names of his children.

But all this has not the slightest resemblance to the signs displayed by the malingerers above described, who showed by the nature of their replies and their whole behaviour that a profounder injury of the mental life was not to be supposed. When a man, who was in possession of complete mental health a few days, weeks, or months before, pretends that he can no longer read and write, appears to have forgotten his name and home, and though entirely without emotional excitement, yet persistently makes false statements about matters with which he has been conversant from his earliest childhood; in such a case simulation may be regarded as positively proved. This mode of deception depends upon the vulgar opinion that everything in a madman must be topsy-turvy, that he can no longer remember his father, his son, and his best friends, and no longer knows how many fingers are in the human hand.

Unfortunately, simulated insanity does not always present itself to us in this simple and easily recognisable form. A malingerer readily betrays himself when he is active, and endeavours to imitate the symptoms of a psychical malady with which he is not acquainted, and which are especially hard for a sane person to reproduce. On the other hand, when he is as passive as possible, keeping perfectly silent, or uttering monotonous complaints, it is often very difficult or even impossible for the most practised observer to distinguish false from true.

Looking back upon a long experience, moreover, the conviction strikes us that simulated insanity is not so frequent as the general public and the courts believe it to be. The question generally arises with regard to criminals who are suspected of simulation when in penal servitude or when undergoing imprisonment prior to trial. But, as is well known, the situation of such persons is in itself highly favourable to the origination of conditions of psychical illness.

Some months ago, a young man, of 29 years of age, who had excited the strongest suspicion of malingering, was sent to us for observation by the Provincial Court of Lüneberg. From his early youth he had been frequently punished for theft, and had repeatedly wandered about under a false name, and with false papers of legitimation. Thus, lying and deceit belonged, as it were to his daily life. It may be imagined with what distrust this man was regarded when, in the course of last autumn, having been taken up for another theft, and being in prison, he suddenly exhibited a total change in his behaviour, after conducting himself quite rationally for four weeks. He lay in his cell with his eyes closed, did not speak, and appeared no longer able to walk, though he sometimes crept on his hands and feet. He took no notice of the outer world. Only he sometimes told the physician that he wished to be brought to the High Court of Justice at Leipzig, and that he was under the influence of a magnetic mirror, which a man in Lüneberg possessed. After he had remained in this condition for five months without change he was brought to the asylum at Hildesheim. He had to be carried out of the vehicle in which he had been conveyed to the institution, for he was not to be induced to stand upon his legs. In the asylum he lay in bed almost motionless. After two days we succeeded in rousing him from this apparent torpor. He dressed himself, went to walk in the garden, ate in company with the other patients, and showed no

trace of his former condition of torpidity. But he remained very taciturn. He spoke to the physicians, however, of his urgent wish to be brought to Leipzig. He said he had committed a crime there, for which he would need to be punished. He did not say another word about the magnetic mirror which he had sometimes mentioned at Lüneberg. For weeks, in spite of the most careful observation, we could form no definite judgment as to the condition of this man, so enigmatical in many respects, till he declared one day that he had important revelations to make, which he would only announce formally, in the presence of the officers of the institution and the chaplain. Accordingly, next day he was brought into the ordinary consultation room, and there, in flowing language, and with an expression of the highest passion and conviction, gave out a perfect flood of delusions of persecution. His statements altogether referred to the period of his imprisonment in Lüneberg. He said the officers of the prison who, had wished to make him unhappy, had induced his betrothed to come from Hungary to Lüneberg by false pretences; had ill-used her in the most horrible manner, and had murdered her in prison. They had also committed other disgraceful acts and murders, which he reported with a careful recounting of all the particulars. People had talked over all this close to his cell, under the impression that he could not hear it. The way in which he delivered this, the lively tone of his description, full of conviction, and the introduction of the very turns of expression which he believed he had heard—often quite uncommon in their sound—permitted no doubt to remain that a morbid delusion, founded upon sensory hallucinations, here presented itself. I could, therefore, definitely express my opinion from these facts that the man was insane, which was recognised by the Court without further question.

I venture to communicate the following as an additional example of the difficulty which a perfectly passive behaviour may offer to one who is seeking to form a judgment of doubtful mental conditions.

In October, 1876, a young man was discovered in the village of Wendhausen, in the neighbourhood of Hildesheim, whose apparent helplessness caused the authorities of the place to take charge of him. He seemed between 25 and 30 years of age, and was in perfectly good health physically. His demeanour was shy, uneasy, and depressed, and he did not speak a word. All the endeavours of the police to find out his personal circumstances entirely failed of success. He was transferred to the asylum at Hildesheim.

The observation of this waif proved that his hearing was perfectly normal, and that he must, therefore, possess the power of speech, since he did not suffer from imbecility of the graver type. He recognised coins when they were laid before him, choosing particular ones correctly when told to do so. He showed himself not inexperienced in domestic work and garden labour. In a general way his behaviour was not peculiar, though always somewhat uneasy and reserved—at the same time patient in the highest degree and free from all irritability. In no way could he be induced to speak. Not even the softest sound has ever been heard from him. He has now been longer than three years in the asylum, and his behaviour has in no way changed. He is an industrious and conscientious worker, closely observes the hours and regulations of the establishment, and shows no disposition to escape, so that he can be allowed to go about quite freely. His whole interest concentrates itself on the little circle of his daily employments. Other things he pays small regard to. He takes no part in the amusements of the patients. Seldom is a trace of any kind of emotion perceptible in his features, unless one counts as such an almost imperceptible smile, which is occasionally observed.

In what way is the behaviour of this man, particularly the complete speechlessness, to be understood? Speechlessness exists where hearing is absent (deaf mutism), in cases of paralysis of the organs of speech, in idiocy of the lowest grade, and in certain other forms of insanity besides. It is most general in melancholia cum stupore, but it is also observed in other forms of melancholia, as well as in secondary imbecility, and more rarely in delusional insanity. It is usually but not always associated with great stupidity. I have observed a considerable number of perfectly speechless lunatics, who showed a tolerable degree of intelligence, and were good workers. These patients are, doubtless,

under the influence of powerful delusions, and believe that they are not allowed to speak, just as other patients believe that they are not allowed to eat.

In this way we must explain the speechlessness of the patient above described.

The question of simulation was necessarily considered at first, for the suspicion suggested itself that an individual discovered in such an unusual condition would have reasons to conceal a guilty past by obstinate silence. This suspicion cannot now be entertained, since several years' observation has given no grounds to assume the existence of an intentional deceit.

Such experiences show how careful one must be in forming a judgment of doubtful mental conditions.

In my opinion the existence of simulation can only be definitely accepted when a pretended lunatic presents a train of symptoms which, according to the experience of science, are irreconcilable with the symptoms of real insanity.

## Clinical Records.

### MEATH HOSPITAL AND CO. DUBLIN INFIRMARY.

#### BRIEF NOTES OF OPERATIONS,

Under the care of LAMBERT H. ORMSBY, F.R.C.S.,  
Lecturer on Clinical and Operative Surgery.

(For these Notes we are indebted to Mr. J. F. CAMPBELL.)

OPERATION I.—*Flap Amputation of Thigh.*—J. O'C., *æt.* 23, admitted on the night of the 12th March, 1881, at about 9 o'clock, suffering from a compound complicated fracture of the leg and thigh, with great contusion and laceration of soft parts.

*History.*—He was engaged in shunting railway waggons, when his foot slipped, and the wheels of two loaded waggons passed over his leg and thigh. He was taken up in a very collapsed state, having lost a considerable amount of blood. He was then carried to the hospital on a door, and Mr. Ormsby immediately sent for, who considered primary amputation necessary. Operation performed an hour after his admission, the patient being placed under the influence of ether. Amputation of the upper third of the thigh by antero-posterior flaps was performed.

OPERATION II.—*Amputation of Great Toe at Metatarso-Phalangeal Joint.*—John Q., *æt.* 58, an old sailor, was admitted under the care of Mr. Ormsby on March 4th, suffering from destructive ulceration of the left big toe, the result of carious disease.

*History.*—Stated that his foot had been frost-bitten some months before, and the toe and soft parts began to ulcerate, and small portions of bone frequently made their appearance through the wound.

Operation performed on March 9th. The patient was put under the influence of ether, Ormsby's inhaler being used. The remainder of the toe was removed at the meta tarso-phalangeal articulation by an inverted  $\lambda$  incision. 1. The wound was well washed out with a large glass syringe of water. 2. All blood clots removed. 3. The wound was then swabbed out with a solution of chloride of zinc (40 grains to the ounce). 4. The edges of the wound then brought in apposition without inducing any tension of parts. 5. And the wound carefully covered and bandaged up so as to exclude air. In all operations these five precautions are carried out by the operator, and very few of his cases are ever followed by suppuration where this modified plan of antiseptic surgery is adopted.

OPERATION III.—*Fistula in Ano (Incompleta).*—Peter M., *æt.* 27, a car driver, admitted into Meath Hospital on March 7th, suffering from fistula in ano.

*History.*—Stated that the fistula was the result of an abscess at side of anus (ischio-rectal). On examination it was found to be an external blind fistula, a probe passing upwards for about half-an-inch in a sinuous tract at side of rectum. The chest and abdominal viscera having been carefully examined and found all healthy, an operation was therefore decided upon. On March 9 the patient was placed under the influence of ether, an assistant keeping

the nates well asunder. Mr. Ormsby introduced a director through the external opening of the fistula, and passed it up as far as it would go. He then passed up a rounded portion of a wax candle into the rectum, and along the director in the fistula he passed a sharp-pointed curved bistoury provided with a good blade and strong handle, the point of which was then pushed through the wall of the rectum into the side of the candle already inserted, and with a sawing motion the portion of tissue, together with the sphincter between the fistula and gut, were completely divided. A morphia suppository was inserted into the rectum; a small piece of lint was then carefully introduced deeply down into the incision; a pad of lint then placed over all between the nates, and kept in firm apposition by a T-bandage, and the operation thus completed.

OPERATION IV.—*Fistula in Ano (Complete)*.—John J., æt. 45, was admitted into Meath Hospital in March, 1881, suffering from fistula in ano, the result of an abscess in the ischio-rectal space. History states that some three months ago he got a severe wetting and an abscess formed at side of anus which burst of its own accord, a fistula then remained which discharged a thin yellow fluid ever since, very irritating in character and faecal in odour. On examination it was found that a probe passed through a very small pin-hole opening at side of a nus upwards for about an inch, and finally found its way into the gut, the point of which was easily detected by the finger when passed up into the rectum, demonstrating the completeness of the fistula. The chest and abdominal viscera having been carefully examined and there being no other contraindication to operative measures, on March 9th the patient was placed under the influence of ether, and the nates having been well divaricated by an assistant, Mr. Ormsby passed a curved director upwards through the external opening until he felt the point passing through the internal or rectal opening. Along the director was then passed a probe blunt-pointed curved bistoury, until the point of it was felt by the finger in the rectum, and then, by a sawing motion, the tissues between the fistula and gut were carefully divided. A piece of oiled lint was placed between the freshly cut surfaces, which were kept in apposition by another pad of lint and a T-bandage, and a morphia suppository was then inserted to allay pain and prevent the action of the bowels and the operation was completed.

## The Mineral Waters of Europe.

### THE "MEDICAL PRESS"

#### ANALYTICAL REPORTS ON THE PRINCIPAL BOTTLED WATERS.

By CHARLES C. R. TICHBORNE, LL.D., F.C.S., F.I.C.,  
President of the Pharmaceutical Society of Ireland, &c.

WITH

#### NOTES ON THEIR THERAPEUTICAL USES.

By PROSSER JAMES, M.D., M.R.C.P.Lond.,  
Lecturer on Materia Medica and Therapeutics at the London Hospital, Physician to the Hospital for Diseases of the Throat, &c.

(Continued from page 318.)

We find that bottled specimens of Vals waters give such different results from the original analyses, that we subjoin one for comparison, premising that we have converted grammes per litre into grains per gallon.

#### *Désirée (Ossian Henry).*

Bicarbonate of lime	...	...	39.97
Bicarbonate of magnesia	...	...	63.00
Bicarbonate of soda	...	...	422.80
Bicarbonate of potash	...	...	18.41
Bicarbonate of protoxide of iron	...	...	0.70
Chloride of sodium and potassium	...	...	77.00
Sulphate of soda	...	...	14.00
Sulphate of lime	...	...	14.00
Alumina	...	...	4.06
Total solids	...	...	653.94

We now give our analysis of another of these waters:—  
*St. Jean.*

Bicarbonate of sodium	...	...	65.00
Bicarbonate of potassium	...	...	1.75
Carbonate of calcium	...	...	8.43
Carbonate of magnesium	...	...	2.98
Carbonate of protoxide of iron	...	...	0.30
Chloride of sodium	...	...	2.13
Chloride of potassium	...	...	0.50
Sulphate of sodium	...	...	2.37
Sulphate of calcium	...	...	3.07
Alumina	...	...	0.50
Total solids	...	...	87.03

Free carbonic acid not determined.

#### *Skeleton analysis of Half-a-pint (10 fluid ounces).*

Total Solids.	Antacids.	Salines.	Purgatives.
5½ grs.	5 grs.	1-10 gr.	1-10 gr.

#### *Dominique.*

We have now to consider that curious spring called Dominique, certainly curious when taken in connection with the general composition of the Vals waters; however, if we take a glance at the analysis of St. Jean, we see that a marked change is evident therein from the previous waters which assimilates it to the Dominique.

The published analysis of the Dominique spring is as follows, per 1,000 grammes:—

Sulphuric acid	...	...	...	1.30
Silicate	} of Sesqui-oxide of Iron.	}	}	0.44
Arsenate				
Phosphate				
Sulphate				
Lithia	...	...	...	...
Sulphate of lime	...	...	...	...
Chloride of sodium	...	...	...	...
Organic matter	...	...	...	...

Total solids ... .. 1.74 per  
litre = 121.80 grains per gallon.

Our analysis give us the following results, in grains per gallon:—

Carbonates of calcium and magnesium with iron precip. on boiling...	...	5.00
Silica	...	0.70
Alkaline salts, including sulphate of sodium and chloride of sodium	...	11.36
Sulphate of calcium	...	10.80
Arsenic	...	0.05
Organic matter, containing albuminoid ammonia	...	0.003
Free ammonia	...	0.012
Nitric acid	...	0.069
Free carbonic acid not determined.	...	...
Total solids	...	27.993

Throwing out of consideration the Dominique Spring the Vals Waters may be viewed as well marked alkaline waters, the antacid properties of which are chiefly due to carbonate of soda, as evidenced by its marked action on phenol-phtalein on warming—St. Jean being very much of the same character as the others, only much

weaker, Magdeleine and Precieuse being almost identical in strength and character, the chalybeate character being well marked in each. St. Jean has been recommended as a table water, and although 1-10 grain of sulphate of sodium is present, it might probably be used with advantage for such a purpose where a slight aperient water is desired particularly, as the accompanying salines are not high. The Vals waters seem to be fairly free from nitrogenous organic matter, but are not waters which are calculated to keep very well for any length of time in the bottled condition. As regards the Dominique water, as it is put forward as an arsenical water, we have endeavoured to give an estimation of the amount of arsenic present. The previous analysis do not give any estimation of that important ingredient, and although it is attended with some difficulty, as the arsenic seems to be carried down with the deposit, it would appear to contain on an average about 0.05 grain.

### Special.

#### SANITARY APPLIANCES AT THE BUILDING EXHIBITION.

THE exhibition of building appliances and materials at the Agricultural Hall, Lalington, possessed many attractions to invite the attention of all interested in improved house construction and general sanitary arrangements, as well for invalids as those in the enjoyment of robust health. It is a satisfactory sign of the reality of that advance made in recent years in the way of sanitary reform, that enterprises of the kind carried through at this exhibition, are rendered capable of extended good by stimulating the ingenuity of inventors to produce mechanical adaptations fitted to meet the needs expressed by theoretical inquirers; and in the extent to which invention is carried we are able to note a striking proof of anxiety to perfect to the utmost the health preserving appliances that conspicuously figure in the construction of modern residences. One important feature in every dwelling, ventilation, is provided for by innumerable patents, all designed to secure the adequate removal of impure air, and the introduction of a purer medium for breathing purposes. Among the apparatus of this kind exhibited at the Agricultural Hall, that of Messrs. Robert Boyle and Son possess advantages that apparently give it undoubted superiority over other contrivances devised to effect the same object. A system of air-pump ventilators shown by this firm, for application to dwelling houses, is a most excellent arrangement for preserving a constant purity of atmosphere within it; the ingenious manner in which a constant outgoing current is maintained in the main exit pipe, being especially commendable. In connection with it, too, a heating apparatus can be fixed, by which ingoing air is warmed before circulating in the house, and the simplicity of the whole apparatus is such that the working of it must be most successful in practice. Messrs. Boyle and Son have also a patent chimney cowl, which, for excellence of results in the curing of persistently smoky chimneys, and ease with which it may be cleaned and kept in effectual working order, is incomparably the best with which we are acquainted.

In connection with heating apparatus the multitubular gas boiler of Messrs. John Jones and Sons is a cheap and powerful assistant in readily procuring a large volume of warmed air for halls, conservatories, &c., when there is a ready exit for

the products of combustion of the gas by which the water is made hot. For extensive warming, the "Double L" saddle boiler, invented by this firm, is an improvement on older forms, and should approve itself where economy is necessary, as in large public institutions, hospitals, &c.

One of the most useful and necessary helps to healthy living exhibited was Fielding's Patent Water Filter. This, as the accompanying illustration shows, is soldered on to the supply tap, and by an ingenious arrangement can be adjusted to pass pure filtered water, or the unfiltered fluid as may be desired, being in fact a double acting filter. That figured here is the singly acting instrument, and admits only of filtered water being drawn at all times. This instrument is, in effect, a metal box containing a filter bed of animal charcoal, to which the water gains access after passing a layer of woollen material that detains all mechanical impurities. Its features are simplicity of construction, efficiency in action, and certainty of effect. We have known these filters in use for some time, and cannot praise them too highly. In all large towns, where the water supply is of uncertain quality, they will materially assist in the maintenance of hygiene.

A very large assortment of water-closets, made on numerous improved principles, shown at the exhibition, demonstrate the importance now attached to this essential adjunct of every dwelling-house. In the majority, however, faults exist that go far to interfere with the advantages otherwise possessed by them. Wherever metal is retained as part and parcel of the closet, in relation with the soil flow, it cannot but occur that it will serve to harbour more or less effluvia yielding material; and in spite of the many ingenious devices for rendering the chances of such an occurrence as small as possible, objection will always be legitimately taken to that form of closet in which they are permitted at all. Bostel's Brighton "Excelsior," valveless water-closet, however, obviates this serious defect by means of its construction—entirely of earthenware; and, moreover, closet and trap are one piece only, thus doing away with the mischief always to be apprehended when joints between the two are necessitated. The patentee of this closet supplies with it also an automatic cistern, from which, on the handle being raised a second or two only, a full unbroken flush of two or more gallons of water is quietly given, and closet and trap thoroughly cleaned. By means of a curve given to the trap and soil-pipe, a water seal of one and a-half inches remains, thus rendering the upward escape of sewer gas into the house impossible. The simplicity, cheapness, and effectiveness of this closet unquestionably mark it out as the one most adapted to the needs of the age. An

additional security against noxious emanations is afforded by an admirable invention called the "antiseptic apparatus."

This consists of a metal box containing a considerable supply of permanganate deodorising fluid. From this box a tube conducts the liquid to the upper part of the basin of the closet, and a lever in connection with the handle of the latter forces a portion of the deodorant into the pan. It thus flows

in at the end of the influx from the cistern, and remains until the apparatus is again brought into action. The application of this arrangement to the "Bostel" closet would tend to secure the most perfect form of water-closet yet invented.

Invalid furniture was not very largely exhibited, but among the few things admitting of description in this class, especial reference must be made to the patent pillow divider, by Messrs. Chorlton and Dugdale, of Manchester, which the accompanying engraving illustrates. This is an instru-

ment likely to be of inestimable service wherever it is necessary for two people—one of whom is an invalid—to occupy the same bed. It consists of a cushioned arm, curved to project over the pillow, and fixed by a clamp, adjustable to any position, to the bedstead. When not in use for the purpose of separating two sleepers, it can be utilised as a cup rest or support, being to this end removable to the outer part of the rail, or indeed to any situation on it. Attention is well worthy of being generally directed to the pillow divider, as its value is undeniable. Patient and nurse may, by means of it, sleep on the same couch; and in the case of children's illnesses, the security from disturbance by the restless turning to and fro of the little ones is likely to be widely appreciated. In many instances of two persons in the same bed, too, it will

serve to prevent the possibility of one breathing air already respired by the other; and under innumerable conditions it will admit of practical employment with evident advantage. An invalid couch, named the "Matlock," fitted with patent

spring mattresses, is a convenient piece of furniture, manufactured by the same firm, who likewise show a hospital and infirmary bed fitted with their patent metallic mattress. The construction of this latter, here shown, admits of varying degrees of inclination to the patient. Its use will greatly tend to promote comfort; and in chest affections, particularly, will materially enhance the resources of the physician.

The growing employment of electric and pneumatic bells affords ample scope for the ingenuity of inventors and makers of these modern appliances of comfort; Mr. Zimdars' collection of these instruments formed one of the most interesting features of the exhibition. The perfection to which Mr. Zimdars has brought his patents will admit of unqualified praise being given to them. Especially deserving of notice is the admirably compact little instrument intended for the use of invalids, which is supplied, complete with all necessary apparatus, at two guineas. The excellent workmanship, accurate performance, and inexpensiveness of these calls, their certainty of action as compared with electric bells, and the readiness with which they respond to the least impulse, entitle them to rank as indispensable accessories to every sick room.

Messrs. Henry Tyler and Sons showed window blinds for outside use, elegant in appearance, and exceedingly cheap in price, suitable for fixing to the windows of rooms occupied by invalids and convalescents. They have also a child's cot for hospitals, possessing many favourable features.

The inventor of the well-known "charlaine blankets" has added to the former kinds already in use one intended for employment in hospitals and sick-rooms. The middle wool layer is impregnated with carbolic acid, and thus will largely aid in fending off the infectious elements that gather round a centre of disease. It is an invaluable improvement of an invaluable article, and will, without doubt, be extensively appreciated. These blankets are so light, warm, and inexpensive, durable and elegant, while being also a hygienic ground an improvement on the ordinary bed-clothing, that the favourable reception hitherto accorded to them deserves to be more widely extended.

GENTLEMEN bequeathing money to any charitable institution should be particular to describe such institution accurately. According to the *Charity Record*, the Royal London Ophthalmic Hospital, Moorfields, was left £500 by a lady, but, the institution not having been correctly named, claims were made by other hospitals, and the matter being placed in the Court of Chancery, only £119 18s. has been awarded to the Royal London Ophthalmic Hospital.

THE ETHICAL QUESTION.

THE excitement created by the conduct of Dr. Quain in consenting to meet a gentleman in consultation with whom he could not, so long as the latter preserved his connection with an unscientific and unrecognised school, act in sympathy, or to any satisfactory end, opens up questions which it were well to settle at once and finally. Homœopathy has, fortunately for legitimate medicine, effectually demonstrated its claim to be considered a thing of itself and by itself; divorced by the nonsensical absurdities of its requirements from all association with *bond fide* practice; admittedly pandering to the extravagant vagaries of a section, and that no large one, consisting mainly of unreflecting and imaginative invalids; reducing its adherents to a dead level of fanciful dabblers in the semblance of medicine; it has long ceased to have any hold on the educated physician, who regards it as he would regard any other relic of unenlightened ages, as a mischievous creation which has been powerful for evil, but which has yielded before the light of reason and of truth, and has receded to the position it rightly deserves to occupy—that, namely, of an exploded error. There are, however, still some who find it expedient to avow themselves believers in Hahnemann's ridiculous assumptions, and this because there are

still fee-givers enough to make it worth while that some should announce themselves ready to accept the reward of apostasy, and who reap the pecuniary advantages that are always found to accompany any outrageous professions; and from our knowledge of the class of homœopathic practitioners we consider they may be separated into two groups, one being homœopaths by necessity, the other by repute. It is hard to say for which we ought to entertain the greatest objection, for each alike insidiously works harm both to the science of medicine and to the people whom doctors seek to help. We cannot but regret the existence of a willingness to perpetuate error, as it is being perpetuated in this way; but especially is it a matter for deep concern that popular ignorance is the basis on which the various unorthodox followers of Æsculapius pursue their calling. Could we but train the people in the outlines of pathology and therapeutics, could we but enlighten them only a little in the direction of what is meant by the "healing art," and we should see them the first to express themselves in strong disapproval of the delusive system to which they had yielded in ignorance.

With the delusion of homœopathy we do not propose to trouble ourselves here, farther than to express the regret we feel that it should receive the countenance it does from gentlemen who are intellectually able to riddle its pretensions. There is no point in the assertion that their capacity argues in favour of the views they espouse; this is by no means the case, and in proof we have the public statement of one who is first among them, to the effect that he regards homœopathy as he would another plaything, as an instrument to use or to neglect as occasion served his purpose. What we desire to consider for a moment is the ethical question of whether any, and if any how much, recognition should be given by a physician to a homœopathist, whether he is such by profession or by repute. We find it said by one of the latest defenders of this school that "Medicine-mongers and leeches, Worshipful Companies of Apothecaries, Colleges of Physicians and Surgeons—Royal and Imperial—have all united to do him (Hahnemann) to death; the serial journals of the world, medical and surgical, have, with one accord, combined to bespatter his name with dirt, or they have entered into a conspiracy of silence to mum him and his homœopathy to death." This is not the puerile raving of a new disciple, but the calm utterance of one of the "lights" of homœopathy, who thus unconsciously exposed the utterly ridiculous nature of his creed, while seeking to defend it before an annual gathering of the *élite* of homœopathy. One cannot but smile at the sublime self-assurance that thus counts as nothing the united opinions of the great masters of medicine and surgery, and puts in apposition with the universal condemnation of Hahnemannism the wordy echoes of a hundred years. The pleas they advance are vain and bottomless; in place of reason they enthrone a mystery, a potentiation; and by reason of the charlatanism that surrounds them, they are naturally debarred from receiving that consideration the absence of which they are incessantly lamenting. The dignity of medicine, and the status of a physician alike, demand the utmost circumspection as to whom and what he consents to accept as having a right to influence his opinion. By lengthened study and experience, he has attained to a knowledge of the phases of disease, and the

means by which he can hope to combat its effects, which are truths he may not be false to. It is no mere question of professional etiquette, then, that leads him to spurn any suggestion tending to alienate him from the convictions forced on him by years; it is indignant repudiation that comes from him, repudiation of any false thing that would ignore or destroy his faith in the principles that guide him; and as he would scorn as a man to accept for a moment what he knew to be a lie, so must he, as a physician, refuse to connect himself, with what is for him a professional error. A man without a qualification may possibly be as competent to treat disease as the president of any Royal College, if he have fitted himself to do so; but, since the number of unqualified physicians or surgeons is inconceivably small, and as qualification is a stamp of efficiency, consultations are rightly enough refused, except with legitimately qualified practitioners. It may be harsh, perhaps, to call every unqualified practitioner a "quack," but it is by no means unnecessary or unjustified; neither is it an undue exercise of privilege to refuse association with whoever fails to regulate his practice of medicine by the laws which are the only ones found true by the experience of ages. Right and wrong preserve their meaning when applied to treatment, and practitioners of opposite schools cannot agree. This is an elementary truth that seemed to have been generally recognised until recent events served to excite a doubt concerning it. That Dr. Quain could not agree with one who was a homœopath, he at once recognised, and acted on. But, whether wisely or not need not be further discussed, he chose to inquire whether a reputed unorthodox practitioner had, for the nonce, resigned his rôle, and reverted to the teachings of science; the result was to show that homœopathy is a name now, whatever it may once have been; and the rest we know. We cannot help thinking that Sir William Jenner's course of action will most commend itself to the profession, as indeed was sufficiently shown when his election to the presidency of the Royal College of Physicians vetoed the censure he challenged on his conduct. He cannot but be satisfied that he correctly expressed the feeling of practitioners of legitimate medicine when he throughout refused to meet or discuss in any way with one who for him, and for all physicians, has no professional status, so long as by practice or by repute he is dissevered from the medical profession.

#### STIMULANTS IN THE ARMY.

THE subject of drunkenness in the army was recently discussed in the House of Commons. According to statistics quoted, out of a total number of 14,750 punishments inflicted during the past year, there were 1,895 courts-martial for drunkenness on duty, and 2,526 for simple drunkenness; the total number of fines for this vice, 44,374, equal to 236 per 1,000 strength; these inflicted upon 23,316 men. Among the proposals submitted with a view to diminish the vice in question, it was suggested that the sale of intoxicating liquors in canteens in garrison, and the spirit ration on the march should be discontinued. This argument was supported by references to opinions expressed by well-known military officers, that "experience had proved that the less liquor there was consumed in an army the more efficient was its con-

dition;" that "men who did not drink at all worked the best and held out the longest;" and that "the absence of crime amongst total abstainers in the army was almost incredible—equal to only 0.12 per 1,000, as against 4.68 in non-abstainers." On the other hand, it was argued that a prohibition of the kind would drive the soldier from the canteen to the public-house; that the sale of spirits in canteens was already prohibited at home stations, and abroad was only carried on by permission of the commanding officer, and that in eleven months no cases of drunkenness due to canteen drinking had come under notice. Various other opinions were at the same time expressed—that it would be better were public-houses in the vicinity of barracks suppressed; that soldiers are not more drunken than civilians, and therefore restrictive measures are not only not necessary with regard to the former, but that their effect would be to drive men to excesses of other kinds. On the general subject the Secretary of State for War took an eminently practical view when he declined to adopt so drastic a remedy as the entire prohibition of spirits. "He would do all he could to discourage the sale of spirits to soldiers, but he could not agree to stop canteens, and so, in garrison towns, drive soldiers into public-houses, where they would get worse beer than in them, with worse associations."

Looking at this subject from a medical point of view, and while granting to its fullest extent the very great evils, alike to health, morals, and public convenience, that are due to drunkenness, the question occurs whether, considering the nature of the duties performed by soldiers, and the circumstances in which they are placed, the moderate use of spirits is not on occasions actually beneficial as a medicine, on others, equally so as a solace. There has, indeed, of recent years been an active movement on foot to suppress, by means of enactments, the issue of spirits even in moderation to soldiers; and numerous authorities have been quoted in support of the measure. What, however, is a somewhat noticeable circumstance is that similar quotations do not appear from expressed opinions of men equally high as authorities, but who, for the sake of the soldier himself, oppose the complete withdrawal of his spirit ration. The real bearings of the question refer to active service in trying climates, more especially those that are characterised by damp, heat, and *malaria*. Of such, Perak furnishes a ready example; and with regard to that place, the statement occurs in a Departmental Blue Book that in the recent expedition to it, the soldiers who drank their rum were much more healthy than were the total abstainers. In Abyssinia soldiers, so long as they were deprived of drink, were unable to digest and assimilate the inferior and badly-cooked rations upon which for some time they had to subsist. During the advance of our troops to the river Prab, on the occasion of the Ashantee War, the men were encouraged in their daily journey by the prospect of receiving a ration of spirits at its conclusion; and in respect to the very famous marches performed during the War of the Secession in America, the troops being, as stated, restricted to teetotal principles, the circumstance some time afterwards transpired that while so engaged they received as "a tonic," and more than once daily, a very palatable concoction, of which whisky constituted

the greatest bulk. But among the most *advanced* of the sanitary reformers, there are some who assign all kinds of dreadful effects upon the nervous system to the free indulgence in coffee and tea. What, then, is to be done? Moderation in all things, drinks, whether non-alcoholic or alcoholic, amongst them. But let us beware of sacrificing *utility* altogether to a mere idea.

## Notes on Current Topics.

### Sir Wm. Gull's Latest.

It is with the greatest amazement we have seen a letter in the daily press wherein Sir Wm. Gull extends the *egis* of his protection to the President of the Royal College of Physicians against whoever would censure the latter for refusing to meet a homœopath in consultation. We are inclined to ask if *any* public question can arise which will not afford Sir Wm. Gull an opportunity of gratuitous exhibition. In this, as in former cases, the interference is uncalled for, and calculated to serve the object of the ubiquitous baronet's concern.

### Death of Dr. Hardwicke.

MR. HARDWICKE, the well-known coroner for Central Middlesex, and familiar to newspaper readers as Dr. Hardwicke, died, we regret to learn, on Thursday last. He had held an inquest at Finchley, whence he proceeded to the City, and soon after reaching there he was seized with an apoplectic fit, out of which he failed to recover. Deceased was a Member of the Royal College of Surgeons, England, and Licentiate of the Apothecaries' Society, and was widely known as a practical hygienist, his "Overcrowding in the Dwellings of the Poor" having shown him to be deeply and thoroughly interested in the improvement of the sanitary condition of large towns. A feeling of very general regret will be aroused by the death of one whose geniality and heartiness had come to be universally recognized and acknowledged.

### An Electric Railway.

CHIEF among the attractions of Easter-tide at the Crystal Palace is an electrical railway, consisting of a line of rails in the grounds, on which run an engine and three passenger carriages, the motive power being generated by an eight-horse Siemens machine in a hut erected close by. The current is conducted to the middle of three rails placed 9½ inches apart, and from it passes along a wire brush attached to the locomotive to this latter, the return circuit being along the outer rail-line. In the locomotive is a mounted Siemens machine, the engine, in fact, consisting of a neatly boxed-in dynamo-electric apparatus. A weight of three tons can thus be drawn at a rate of ten miles an hour; accommodation is provided in the coaches for eighteen passengers. The superior conductivity of the ironwork to that possessed by the earth for electricity, wooden sleepers being the support of the rails, is the fact chiefly depended on in the construction of the whole arrangement, which, for the short extent to which it is worked—about 325 yards—at the Crystal Palace, answers very satisfactorily indeed. This

is, too, the first opportunity London sight-seers have had of seeing the novel application of electricity as a means of locomotion, the machine having been exhibited hitherto on the Continent only. It would, perhaps, be premature to imagine that this successful application of the force is an indication of its fitness for traffic purposes; but it, at any rate, teaches how the ingenuity of inventors is being exercised to overcome whatever practical difficulties the matter may present.

### The Jacksonian Prize.

THE Jacksonian Prize was, at a meeting of the Council of the Royal College of Surgeons of England, on Wednesday last, awarded to Mr. Cheyne, M.B. Edinburgh, F.R.C.S. Eng., Assistant Surgeon to King's College Hospital. The subject of the essay which obtained this distinction for its author, is, "The History, Principles, Practice, and Results of Antiseptic Surgery," and it will be remembered that for some considerable time he has been actively engaged assisting Professor Lister in his researches. Mr. Cheyne obtained last year the Boylston Prize and Gold Medal for an essay on "Antiseptic Treatment; What are its Essential Details? How are they best carried out in Practical Form?"

### Artificial Eyes.

It would be interesting to know to what extent artificial eyes are in use in this country; the number must be something considerable if it in any way reaches to that found in Chicago, where 600 to 800 per year are sold. Some interesting details as to the manufacture of these are supplied by an American paper, and it is said that the occurrence of finer silicates than usual at Uri, in Switzerland, has led to the chief manufactories being situated there. Such eyes are, it is urged, better able to withstand the corrosive action of tears and mucous secretions than those of French make, and we believe the Chicago pattern is not unknown in this country. The artificial eye is a delicate shell or case, very light and thin, and concave, so as to fit over what is left of the eyeball. The shell is cut from a hollow ball or bubble of glass, the iris is blown in, and then the whole is delicately recoated. The trade in Chicago has undergone a curious change. Twenty years ago there were sold very many more dark eyes than light, but from that period the sale of dark eyes has been perceptibly dying out. About twenty light eyes are now sold to one dark. In Boston the percentage is even larger—about thirty-five blue or light eyes to one brown; while, on the other hand, in New Orleans, fifty brown or dark eyes are sold to one light. The change in Chicago is supposed merely to show that the influx of population has been from the East principally, and from Northern Europe.

### Dr. Richardson on the Management of Small-Pox Cases.

At the last meeting of the Sanitary Institute of Great Britain, on Wednesday, April 13, Dr. B. W. Richardson, F.R.S., read a paper dealing with the management of cases of small-pox and other infectious diseases in the metropolis and large towns. Dr. Richardson maintained that there should be no aggregation of these cases in

large central institutions, suggesting that each parish should be required to maintain its own burdens, and accept its own responsibilities for the detention and management of the cases occurring within its boundaries. In connection with this the author of the paper makes the following important proposals in the way of permanent reform, viz. (1) That the sanitary committee or authority in every parish should have all the special centres of infection in each of its districts thoroughly mapped out, and that it should know, on a calculation of cases occurring in quinquennial periods, what is the permanent accommodation required for its infectious sick. (2) That the required accommodation being known the local authorities should keep ready, at all times, within the parish, such necessary accommodation, in small hospitals situated in different parts of the parish or locality. (3) That each hospital should not be larger than is sufficient to receive twenty-four persons at one time, and should be constructed, on the separate system, of iron, so that it may at any time be absolutely purified by fire throughout all its structure; that each should be placed on the upper storey of a building, forming, in fact, the top storey of one or more houses, so that it may be lighted and ventilated directly from its roof, while all the air that passes out of the hospital when it is occupied by infectious persons, should pass through fire. Finally, each patient should be carried into the hospital by a valved lift, which lift should pass through a shaft, so as to draw up air during its ascent, and which should, when required, be effective for flushing the hospital with air. (4) That the general supervision should be in the hands of the medical officer of health; and the nursing, also under the supervision of the medical officer of health, should be carried out by trained nurses, who might be educated to their work in the union infirmaries.

Dr. Richardson suggests also that the medical attendance should be conducted by a special staff of duly qualified medical men, acting under the medical officer of health, and responsible to the local authority, by whom they should be approved and remunerated.

Following the delivery of Dr. Richardson's address a discussion on the points raised in it took place, from which it seemed tolerably evident that the author's sweeping changes were not deemed an essential feature of improvement. The debate, however, will be continued on April 27th, and it may be expected that valuable results will accrue from it.

#### Cremation in New York.

ADVOCATES of a non-pestiferous burial in this country will hear with interest that in New York a Cremation Society has been formed, pledged to assist the movement for making a scientific disposal of the dead universal. The *New York Medical Record*, commenting on the initiation of the new Association, remarks that in Milan the average cost of an ordinary cremation is about ten dollars—two pounds sterling. We shall look to hear of good resulting from the formation of the American Society, and regret that we in England, here, are so long debarred by silly prejudice from enjoying the better atmosphere that would exist apart from the horrible centres of decomposition termed cemeteries.

#### The Dentist Register.

THIS official list of the persons whom the Dental Act and the General Medical Council recognise as being qualified dentists has just appeared. It is a pitiful record of the degradation to which a branch of the surgical profession has been reduced by legislative bungling and administrative incapacity. The book contains 5,266 names, amongst which on search we find the names of 565 practitioners who, there is reason to believe, know something of dentistry, scattered up and down in a list of small jewellers, chemists boys, hairdressers, and tobacconists, numbering no less than 4,698 persons. *Oh tempora, oh mores!* To think that dental legislators have been betrayed by their anxiety for dento-educational reform into such a catastrophe, and that the General Medical Council has lent its hand to the granting of a quasi-surgical qualification to such people, to think that for thirty years to come every druggists helper and every barber-tobacco vendor who thinks it an honour to dubb himself a dentist shall be gazetted as dental surgeon. The *fasco* is indescribable. It is the absurdity of professional legislation, the everlasting opprobrium of the Medical Council, the humiliation of those who made the Dental Act, the warning beacon of would-be class legislators.

#### The Notification of Infectious Diseases.

AT a meeting of the North of Ireland Branch of the British Medical Association, held in the Belfast Royal Hospital, on Friday, the 4th March last, J. W. T. Smith, M.D., President of the Branch, in the chair, it was *unanimously* resolved:—"That in view of legislation on the subject, the North of Ireland Branch of the British Medical Association desire to record their opinion that the onus of reporting cases of infectious disease should not devolve upon the medical attendant."

#### Women as Physicians in America.

THERE is nothing like the logic of facts. To it all theories must be brought and tested. It is vain to attempt to escape its verdict. A valedictory address recently delivered by Dr. Rachel L. Bodley, Dean of the Woman's Medical College of Philadelphia, and published in the *Philadelphia Medical Reporter*, placed this matter before her hearers. Her theme was a statement of the work accomplished in the thirty years of the existence of the College, as exemplified in the professional careers of her 276 female graduates sent out during that time. To enable herself to speak with precision Dr. Bodley sent to each of the 244 surviving graduates (32 had died in the thirty years) a circular containing eight questions, to which she solicited answers. Of the 244 surviving graduates, answers were received from 181, and of this number 151 are in active practice as doctors, the remaining 30 having given up for various reasons, among which are domestic duties, philanthropic work, other business, poor health, retired, and old age. We shall give the words of the lecturer on some of the other points:—"The second question related to the predominating character of the medical practice of the 151 who are thus actively engaged. The responses are as follows: Gynecological practice predominating, 32; obstetrical, 9; medical, 9; surgical 3; general

practice, without discrimination, 34; gynecological and obstetrical, 19; gynecological and surgical, 6; gynecological and medical, 26; obstetrical and medical, 6; surgical and medical, 7. Total 151. The third question relates to the social status of the woman physician in the community in which she dwells. One hundred and fifty-one answer this question, and of these 144 report cordial social recognition. These answers are often emphasized and frequently accompanied by testimonials in proof thereof. Seven report negatively. The fourth question interrogates in reference to the work accomplished by the woman practitioner, as resident or visiting physician in hospital, asylum, charitable institution, or as physician in college or school for girls. To this question 157 make reply: 59 are thus engaged. In the State of Pennsylvania, one is physician in charge of Woman's Hospital of Philadelphia; one is resident physician to the department for women in State Hospital for the Insane of the South-eastern District of Pennsylvania; one is assistant physician of Pennsylvania State Lunatic Asylum, at Harrisburg. In New York, one is resident physician of Nursery and Children's Hospital, Staten Island; one is assistant resident physician, same institution; one is resident physician House of Mercy for Girls (a charitable institution); eight are assistant physicians in the Woman's Hospital of Philadelphia, and in the New England Hospital in Boston; besides these are consulting and visiting physicians to hospitals and charitable institutions, members of consulting boards. The fifth question relates to the monetary value of the medical practice per year, and is answered by 76 ladies. 24 over 1,000 dollars; 20 over 2,000 dollars; 10 over 3,000 dollars; 5 over 4,000 dollars; 3 over 5,000 dollars. Four report sums varying from 15,000 dollars to 20,000 dollars per year. Ten report less than 1,000 dollars per year. The average income is found to be 2,907.30 dollars to each of 76. The four who report the exceptional large sums are established practitioners, and have reported the amount each year for several years. These sums may, probably, be relied upon by the social statistician as fair averages of the income of women physicians, since many are careful to state that they give only actual receipts, as indicated by bank-book or ledger. Question sixth referred to the work for which woman is pre-eminently fitted, that of medical teacher, and specified separately institutions of learning and popular audiences of women. Fifty-four answer this question affirmatively. Among these are seven professors in medical colleges in Philadelphia and New York, and twice that number of lecturers and instructors in the Philadelphia college and in the medical college for women in Chicago. The seventh question is the inquiry which, in later years, has assumed (with us) especial interest, in deciding the professional status of women physicians, viz., that of membership in medical societies. Sixty-six reply affirmatively to this question. "Are you a member of a county, state, or other local medical society?" The professional ability of many of these ladies has been recognized by election to membership in more than one state or local medical organization. Thus, the accomplished author of the Boylston prize essay for the year 1876 reports membership in six societies, five in New York city, and in the American Medical Association. Another alumna practicing in the largest city in Ohio, reports membership in

four societies, three prominent local organizations, and the American Medical Association. To the last question (the eighth) 61 make answer. The inquiry is worded thus: "What influence has the study and practice of medicine had upon your domestic relations as a wife and a mother?" As it is concerning the phase of influence suggested by this question that our critics make their severest comments, so it is the most difficult to present truthfully the impression made by the answers received. The answers of the 50 married ladies who respond to this question tabulate as follows: Influence, favourable, 43; not entirely favourable, 6; unfavourable, 1. Unmarried ladies' reply to this question, after striking out from the line, the words "wife and mother." Three state that the study and practice of medicine have prevented marriage, while a fourth states definitely that she has "remained single for reasons entirely distinct from her profession." A thoroughly conscientious mother writes from her nursery, where three quite young children claim the mother's ministry: "The study of medicine is of great benefit, but the practice often interferes with the duties to my family." The clear, pure quality of the replies, as a whole, is truly inspiring; for example: "Purifying and ennobling. Married a physician since I began practice. Am the mother of a boy of eight years of age." Another: "As wife my duties have never been interfered with; as a mother I have been incalculably benefited. \* \* \* My husband is also a physician. I am often enabled to assist him with his cases, both in diagnosis and treatment, and I often find his advice of great value to me. We are, mutually, a help to each other.

The *Philadelphia Reporter* says that even allowing for the natural bias of the lecturer in favour of the cause she advocates, there can be no doubt but that the results she states will compare very favourably with those from a similar number of male graduates. As far as it goes, it is a strong vindication of the propriety of those women studying medicine who have tastes and talents in that direction.

#### Injury fromarrings.

At the Therapeutical Society of Paris, Dr. Paul stated recently that, simple as is the operation of piercing the ears and inserting the ring for earrings, it not unfrequently—and especially in scrofulous subjects—gives rise to most serious effects. Since his attention was called to it about fifteen years ago, he has been able to collect, without difficulty, one hundred and twenty such cases in which scrofulous eczema or ulceration has appeared, deforming the lobule or cutting it through as clean as the chain of an *écraseur*, and leaving unsightly cicatrices. Union in these cases is effected with difficulty, and renewed piercing of the lobule is followed by the same results. M. Féréol has found, in cases where the metallic ring could not be borne, that ulceration may sometimes be prevented by employing a filiform gum bougie.

#### Prize Essay on Morbid Growths of the Testis, &c.

THE Philadelphia Academy of Surgery offers a prize of five hundred dollars for the best essay on the Surgical Pathology and Treatment of Tumours or Morbid Growths of the Testis, Scrotum, and Spermatic Cord, to be open exclusively to American surgeons. (1) The essay must be

founded solely upon original investigations, be illustrated by suitable drawings, microscopical and otherwise, and be written in scholarly English. (2) The essay shall be the property of the Academy, which shall, at its option, permit the author to publish it at his own risk and expense. (3) Each essay must be accompanied by a motto, and by a sealed letter containing the author's name. (4) The essay must comprise an amount of matter equal to two hundred and fifty pages octavo. (5) The award will be made at the meeting of the Academy in January, 1884, by a committee of the Fellows. All essays should be forwarded to the secretary, J. Ewing Mears, 1,429 Walnut Street, Philadelphia.

### The Metropolitan Water Supply.

DR. FRANKLAND reports of the water supplied to the metropolis during the past month of March that the Thames water supplied by the Chelsea, Southwark, Grand Junction, and Lambeth Companies was of better quality than during the previous month; on the other hand, the West Middlesex Company's water, which in February was the best drawn from the Thames, exhibited in March a noticeable deterioration. The Chelsea and Grand Junction Companies alone delivered water that had not been efficiently filtered.

Of the water derived from the Lea, the New River Company's supply recovered its usual superiority over the metropolitan waters of river origin, whilst that of the East London Company was no better than average Thames water. The supplies of both Companies were efficiently filtered before delivery.

The deep-well waters of the Kent and Colne Valley Companies, and of the Tottenham Local Board of Health, were of their usual excellent quality for drinking, and that of the Colne Valley Company, being softened before delivery, was also well suited for all domestic uses.

### Poisoning by a Bath-heater.

AN inquest was held on Saturday week, at Anerley, on the body of Mr. C. F. Deacon, solicitor, who was poisoned on the previous Tuesday by carbonic acid and carbonic oxide gases, arising from the atmospheric burner of a heating apparatus in his bath-room. Dr. J. S. Turner deposed that these burners, though largely used, were highly dangerous; they produced not suffocation, but direct poisoning, their effect on the brain being similar to that of inhaling chloroform. He had known five or six cases during the last six weeks in which persons had been rendered insensible by these burners, two cases narrowly escaping with their lives, and he advised all his friends who used them to have them at once removed. The jury returned a verdict of accidental poisoning.

SCARLET fever showed the largest proportional fatality in Wolverhampton; and whooping-cough in Portsmouth and Leeds. Of the 25 deaths referred to diphtheria in the large towns, 11 occurred in London, 8 in Glasgow, and 2 in Portsmouth. The highest death-rates from fever mainly enteric, were recorded in Newcastle-upon-Tyne and Portsmouth. Small-pox caused 77 more deaths in London, one in Liverpool, but not one in any of the other large towns.

THE rates of mortality last week in the principal large towns of the United Kingdom per 1,000 of the population were—Portsmouth 16, Leicester 17, Brighton 18, Bristol 19, Bradford 19, Salford 19, Plymouth 20, Sunderland 21, London 21, Leeds 21, Edinburgh 22, Hull 22, Nottingham 22, Sheffield 23, Glasgow 24, Birmingham 24, Newcastle-on-Tyne 25, Manchester 26, Oldham 26, Wolverhampton 27, Liverpool 28, and Dublin 30.

IN the principal foreign cities, the rates of mortality per week, according to the most recent official returns, were:—Calcutta 31, Bombay 31, Madras 48; Paris 31; Geneva 17; Brussels 25; Amsterdam 30, Rotterdam 30; The Hague 31; Copenhagen 24, Stockholm 31, Christiania 16; St. Petersburg 62; Berlin 23, Hamburg 22, Dresden 26, Breslau 36, Munich 36; Vienna 33; Buda-Pesth 34; Rome 27; Turin 30, Venice 24; New York 29, Brooklyn 20, Philadelphia 22, Baltimore 22 per 1,000 of the population.

## Scotland.

(FROM OUR NORTHERN CORRESPONDENT.)

HEALTH OF EDINBURGH.—For the week ending with Saturday the 9th inst., the deaths in Edinburgh rose from 81 to 91, and the death-rate was 21 per 1,000. Only one death from fever was reported in the Old Town, and the southern suburbs were entirely free from zymotic mortality.

EDINBURGH UNIVERSITY COURT.—At a meeting of the Edinburgh University Court, held on the 11th inst., *inter alia*, it was resolved to recognise Mr. George Taite, Ph.D., and Mr. Granville H. Sharpe, jointly, as teachers of medicine in Liverpool, whose course of lectures on chemistry, and course of instruction on practical chemistry, should qualify for graduation in medicine in terms of ordnance No. 8, section vi. (4).

EDINBURGH UNIVERSITY—CHAIR OF PATHOLOGY.—The curators of the Edinburgh University met on the 12th inst. to consider the applications for the Chair of General Pathology, vacant by the death of Professor Sanders. There were present, Principal Sir Alexander Grant, Bart., the Lord Provost, Bailie Colston, Mr. Campbell Swinton, and Councillor John Boyd; Lord Carnhill, and Mr. Duncan MacLaren were absent. The curators, after an hour's deliberation, separated without making an appointment, it being stated that nothing definite could be done in the absence of Mr. Duncan MacLaren. The clerk (Mr. Bruce Johnston, W.S.) was instructed to communicate with Mr. MacLaren, and ask him when it would be convenient for him to attend an adjourned meeting. On the 14th inst. Dr. William Smith Greenfield, London, was elected. The contest is understood to have lain between Dr. Greenfield and Mr. Hamilton, who so acceptably discharged the duties of the chair during Professor Sanders' illness. While we recognise in Dr. Greenfield an excellent appointment, we sympathise with Mr. Hamilton in what must naturally have been to him a disappointment.

GLASGOW WESTERN INFIRMARY.—At a meeting of the managers of this Institution held on the 11th inst., Dr. Hector C. Cameron was appointed surgeon to the new wards of this institution. Dr. Lyon, dispensary surgeon, was also a candidate. At the same meeting, Dr. Gavin Tennant was promoted from the dispensary to the new medical wards. For this office, the irrepressible Dr. Bell, and Dr. MacVail were also candidates. We congratulate Dr. Cameron on his appointment, and on the vindication, in this manner, of the principle, that the directors of such institutions have a perfect right, that it is, indeed, incumbent on them, to select the candidate who seems to be the best qualified, irrespective of the position which he desires to vacate. It is well known that the duties of the dispensary physicians and surgeons are often performed in a most perfunctory manner; and that the prescriptions of practitioners of long standing, are not unfrequently supervised at our public institutions by unqualified

boys in smoking-caps, in the capacity of that nosocomial, Mrs. Harris, "the Heed doctor!" It is absurd for a moment to suppose that the man who regards such an office as merely a sinecure, fails to cultivate the advantages which such a position commands, delegates most of the work often to unqualified subordinates, and merely draws his salary, can urge simple tenure of office as a ground for preference in the matter of promotion.

GLASGOW UNIVERSITY—GOLD MEDAL FOR BOTANY.—Mr. Thomas Smith, L.R.C.S.E., of Heriot Hill House, Edinburgh, has offered to the University in memory of a deceased relative, a gold medal of the value of about £10, to be awarded every second year. The subject of competition is always to be botanical, and the competition is to be open to all matriculated students of the session in which the award is made.

GLASGOW DISPENSARY FOR SKIN DISEASES.—The Annual General Meeting of the subscribers to the Glasgow Dispensary for Skin Diseases was held in the Hall of the Institution on the 13th inst., Mr. A. Orr Ewing, M.P., presiding. Mr. James Graham read the annual report, from which it appeared that the total number of new cases treated during the past year was 1,192 and since the opening of the Dispensary upwards of 2,300 cases have been treated. There is a debt of £1,239 7s. 4d. on the building, and there is a deficiency on the annual subscriptions of £2 7s. 7d. The chairman, in moving the adoption of the report spoke in terms of high laudation of the benefits conferred by the dispensary, and of the eminence of its staff.

COMBE LECTURES IN GLASGOW.—On the evening of the 11th inst., Dr. Andrew Wilson, F.R.S.E., Combe Lecturer, began a course of 15 lectures, under the auspices of the Combe Trustees, in the Church of Scotland Normal School, Dundas Vale, New City Road. The subject of lectures is the "General Physiology of the Human Body in its Relations to Health." There was a large attendance of students and others, the lectures being delivered free. Dr. Wilson gave a sketch of the life of George Combe, the founder of the lectures, and remarked that many of the views of Combe and others, which were regarded as unorthodox thirty years ago, were the accepted facts of to-day. In particular, the idea that diseases were mysterious visitations had been given up by all thinking persons, and a knowledge of the laws of health was now esteemed the surest protection against the illness which before was presumed to be unaccountable. Dr. Wilson then proceeded to describe the place of man in the animal series, and showed that the human body agreed in its general structure with that of every other vertebrate animal. The lectures are to be continued on Mondays and Thursdays at six o'clock until completed. Dr. Wilson's remarks were fully illustrated by diagrams.

DEATH-RATE OF GLASGOW.—The deaths in Glasgow for the week ending with Saturday, the 9th inst., were at the rate of 24 per 1,000 of the population per annum. In the previous week the rate was 22, while at the corresponding dates of 1880, 1879, and 1878, it stood at 24, 23, and 25 respectively.

NEW CHAPTER OF THE "BOOK OF SNOBS."—By a singular coincidence the two leading Scotch newspapers, the *Scotsman* and the *Glasgow Herald*, the same day contained a leading article on a question which has considerably agitated medical circles in the metropolis—the association of Drs. Quain and Jenner, particularly the former, with a professed homœopath, in the treatment of Lord Beaconsfield. Speaking generally, it is not desirable that either medical or ecclesiastical dirty linen should be washed in public, or the performance ostentatiously obtruded on outsiders, who, for the most part, are supremely indifferent to mysteries, compared with which those of the "Heathen Chinese" sink into insignificance. While there is an immense amount of truth in the pungent criticism of the journals in question, we think that the main point in the case of Quain v. Kidd has been completely overlooked. The question of a vast deal of nonsensical and unreasonable etiquette is a totally different thing. There is no escape from the position that homœopathy is either a melanoholy delusion or a vast swindle. It would be too sweeping an assertion to make that all who practise homœopathy are swindlers, for we still occasionally meet with honest men who believe in the story of Jonah and the whale, eternal incineration, and the journey of the albatross from the tropical regions of South America to Arrarat, as fundamental principles in the most momentous of all questions. To human credulity, as it exists in the vast majority

of mankind, there is practically no limit; and it is not too much to believe that there may be honest homœopathic practitioners as there are honest dervishes. But what is the position of a man who, on the one hand, practises that system of medicine—however imperfect it may be—which accords with the common sense and the experience—all but universal—of the best educated men in the profession; and, on the other, that system, the transparent absurdity of which is so gross as not to merit examination. As a man cannot faithfully serve two masters, so he cannot honestly practise two systems of medical science so diametrically opposed. It is God and Mammon with a vengeance. This man must be false to himself, false to his patients, and consequently, we say it without the slightest hesitation, unworthy of association with that dignity and honour which *does* linger in the ranks of the noblest of callings, exercised in the proper spirit. Is it a fact that in the report of the Homœopathic Hospital, for 1879-80, Dr. Kidd's name appears as a "Benefactor?" Is it a fact that until recently the name "Joseph Kidd, M.D., appeared *first* in the list of the 'Medical Council' of the Homœopathic Hospital?" Is it a fact that in the "British Homœopathic Medical Directory" for 1881, Dr. Kidd's name appears under the head "List of Qualified Physicians and Surgeons practising Homœopathy?" These questions demand an answer before flippantly condemning the conduct of Sir William Jenner. We repeat that there is much of medical etiquette which is simple nonsense. We cannot conceive that a medical or any other man can be expected to be restrained by any considerations than such as appeal to common sense, the urbanity, and the courtesy of every gentleman. If medical men (and we admit the profession is far from immaculate) so conducted themselves to a greater extent, prevaricated less to their patients, and "discovered" fewer hidden ailments, the results would be honourable to them and beneficial to society.

#### DEATH OF THE EARL OF BEACONSFIELD.

THE Earl of Beaconsfield died on Tuesday morning at ten minutes to five. His Lordship was conscious to the last, and died calmly without any suffering whatever.

### Obituary.

#### DR. GABRIEL STOKES, MULLINGAR.

WE regret to announce the death of Dr. Gabriel Stokes, which took place at his residence in this town on Friday evening last, at the advanced age of 74 years. The deceased gentleman (who was brother to W. Stokes, of Dublin), came to Mullingar in the year 1841, as dispensary physician, and was afterwards elected to a similar position in Mullingar, which he held till about four years ago, when declining health rendered it necessary for him to resign. Dr. Stokes was also consulting and visiting physician to the Mullingar Lunatic Asylum. In his demise the poor have lost a friend, and the community at large, a talented physician, whose place it will be hard to fill.

#### DR. ABBOTT, OF BRAY.

THIS gentleman, who has been hopelessly ill for many months, passed away last week, much regretted by those amongst whom his ministrations were pursued. He was, up to a few days before his death, a Surgeon-Major in the Indian Medical Service. He entered that service with exceptional honour, being the first Irishman who was successful at the Indian competitive without "grinding," or any other aid than that of his own talent and industry. When in India he filled several civil medical appointments, and having returned home on leave, he cast about for a permanent settlement in Europe. Thus it came about that he was appointed medical officer to the Bray (co. Wicklow) dispensary district, which office he held until his death, although recently his duty has necessarily been done by deputy. Dr. Abbott, had he lived, would probably have achieved much popularity as a private practitioner, and his death causes much regret.

NOTICES TO CORRESPONDENTS.

**✉** CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

**LOCAL REPORTS AND NEWS.**—Correspondents desirous of drawing attention to these, are requested kindly to mark the newspapers when sending them to the Editor.

**READING CASES.**—Cloth board cases, gilt-lettered, containing 25 strings for holding each volume of the *Medical Press and Circular*, can now be had at either office of this Journal, price 2s. 6d. The postal regulations not allowing the Journal to be stitched, these cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

**MR. BERRY.**—Case is marked for early insertion.

**DR. C. N.**—Proof not returned in time last week.

**DR. SMITH.**—An English translation is published by Mr. David Bogue.

**AN INTERESTED ONE.**—Yes, in a week or two, the official announcement has not yet been received.

**"DISPENSARY DOCTOR."**—The reply to our correspondent's query as to the application of "Bowen's Act for Building Dispensaries" will be found under Notices to Correspondents in our last issue.

**DR. BLACK.**—In consequence of a delay in the mail service parcel arrived very late, and only the pressing items could be utilised this week. Remainder will hold over.

**MR. E. T. S.**—Not of necessity. It might occur if the graft had not been properly applied, but in one case where we applied forty-three only five failed. The subject is being much more widely investigated now. Mr. Hoggood's paper was one of the earliest; it appeared in the *Students' Journal*.

**DR. H. LIONEL SMITH**, of Uttoxeter, has been awarded a grant of £17 18s. for efficiency in vaccination.

**A CANDIDATE.**—Any good text-book on surgery; Harris and Parker's "Handbook for the Physiological Laboratory," and Gant's "Guide to the Examinations" will also be useful.

**ASSOCIATION OF SURGEONS PRACTISING DENTAL SURGERY.**—Wednesday, April 20, at 7.45 p.m., Council Meeting: "Casual Communications."

**HUNTERIAN SOCIETY.**—Wednesday, April 20, at 8 p.m., Mr. F. Treves, "On the Diagnosis and Treatment of Scrofulous and Lymphatic Glands."

**CLINICAL SOCIETY OF LONDON.**—Friday, April 22, at 8 p.m., Dr. W. J. Tyson, "A Case of Cross-legged Progression."—Dr. W. Stokes (Dublin), "Cases of Excision of the Tongue."—Dr. Whigham, "Aortic Aneurisms demonstrated by the Laryngoscope."—Dr. T. Stretch Dowsa, "A Case of Anorexia Nervosa."

**ROYAL COLLEGE OF SURGEONS IN IRELAND.**—At a meeting of the court of examiners held on the 4th inst. and following days, the undernamed gentlemen passed the first half of their examinations for the letters testimonial of the College:—William H. Allen, Louis E. Anderson, James A. Baird, Mark A. Brennan, Hugh J. Byrne, Thomas E. Cahill, Baldwin Cahel, James Coane, Sir Charles Coote, Bart., William T. Cuthbert, James H. Daly, Charles A. Daly, Thomas Daly, Henry V. Dillon, J. L. P. Doyle, Frederick W. Elmer, George H. Johnston Fisher, Vicars H. Fisher, Alexander J. Fleming, Richard W. Foley, Shawe Gilman, Richard W. Gilmore, J. M. Harrington, B.A., Richard Hatch, Michael S. Hearne, Johnston G. Hurst, Mathew M. Hutchinson, John J. Irvine, James Keenan, William G. Kennedy, William Kenny, James Laffan, James Lane, William B. McCormick, Charles J. M'Connell, Claudius O'Donnell, Cornelius M'Donnell, Thomas M'Ernerney, Michael M'Hugh, Richard J. M'Loughlin, Mathew J. M'Quade, FitzJames Moloney, James A. Morris, Frank Morrison, Joseph H. Neill, Thomas O'Connell, John O'Keefe, Henry R. Peyton, Frank E. Pim, George C. Porter, Thomas O'C. Redmond, George P. Ridley, Frederick Robinson, William J. Robinson, John A. Scott, William S. J. Scott, Patrick de B. Skerrett, William C. Thompson, Maurice Treston, William H. S. Walker, William Waterhouse, LL.D., George T. Wilkinson, Samuel R. Willis, Edward Wynne, and Michael T. Yarr. Thirty-six candidates were rejected.

**DR. CALDWELL (Coleraine).**—We printed recently an advertisement published by this gentleman side by side with those of other tradespeople in the *Coleraine Chronicle*, and we ventured a friendly hint that such methods of obtaining practice is not usual or worthy of imitation. We are favoured with the following letter thereupon:—

**SIR.**—In regard to your remarks concerning me in the *Medical Press*, I think the matter has been carried too far, copies of your paper having been put into the hands of the non-professional part of the community and hawked about by your agents here for the sole purpose of injuring me. What your reasons are for selecting me an object of your ill-will I cannot understand, as the course I adopted has been pursued by most respectable medical men both in Coleraine and elsewhere; and, as regards my registration, it is none of your business to inquire.

I may tell you that the matter will be investigated in a proper place.

W. H. CALDWELL.

The only observation we think it necessary to make is that we have no "agents" in Coleraine, but we are not surprised that others should regard the course pursued by Dr. Caldwell as discreditable. We are not acquainted with any "most respectable man" who advertises.—Ed. M. P. & C.

VACANCIES.

**Carrickmacross Union.**—Medical Officer. Salary, £120, and £15 as Medical Officer of Health. Election, April 22.  
**Hereford General Infirmary.** House Surgeon. Salary commencing at £100, with board. Applications to the Secretary before April 20.  
**Hospital for Sick Children, Great Ormond Street, London.**—Junior Resident Medical Officer. Salary, £50, with board. Applications to the Secretary before April 27.  
**Kent County Asylum, Barming Heath, near Maidstone.**—Junior Assistant Medical Officer. Salary, £150, with apartments, &c. Applications to be sent to the Superintendent on or before April 23.  
**Middlesex Union.**—Medical Officer. Salary, £100, and £25 as Medical Officer of Health. Election, April 25.  
**St. George's and St. James's Dispensary.**—Physician and Physician for the Diseases of Women and Children. Applications to be addressed to the Committee of Management, 60 King Street, Golden Square, W., not later than April 27.  
**Torbay Hospital and Provident Dispensary, Torquay.**—Senior House Surgeon and Provident Medical Officer. Salary, £100, &c. Applications to the Hon. Sec., not later than May 30.

APPOINTMENTS.

**CLARE, E. S. N., M.R.C.S.E.**, Medical Officer for the Third District of the Calne Union.  
**COLLIER, W. M.B., M.R.C.S.E.**, Junior Resident Medical Officer to the Radcliffe Infirmary, Oxford.  
**CURRY, E., L.R.C.P.Ed.**, Physician to the Salop Infirmary.  
**DR. WATTSVILLE, A., M.A., B.Sc., M.R.C.S.E.**, Medical Electrician to St. Mary's Hospital.  
**DOUGHTY, W., L.R.C.P.Ed.**, Medical Officer to the Wetherall District of the Carlisle Union.  
**FITZGERALD, W. A., M.D., L.R.C.S.I.**, Assistant House Surgeon to the Royal London Ophthalmic Hospital, Moorfields.  
**FRASER, D. A., M.R.C.S.E.**, Medical Officer of Health for the Burnham Urban Sanitary District.  
**HINE, J. C. M.B., M.R.C.S.E.**, Senior Resident Medical Officer to the Radcliffe Infirmary, Oxford.  
**LILLEY, G. H., M.D., M.R.C.S.E.**, Assistant Surgeon to Her Majesty's Convict Prison, Portland.  
**MILLES, W. J., F.R.C.S., L.R.C.P.**, House Surgeon to the Royal London Ophthalmic Hospital, Moorfields.  
**NEWTON-CLARE, E. S., M.R.C.S.E.**, Medical Officer to the Third District of the Calne Union.  
**ROBSON, E. S., L.R.C.P.Ed.**, Medical Officer to the Eastern District of the Durham Union.

Births.

**BRAYN.**—April 12, at 22 Penn Road Villas, Holloway, the wife of E. Brayn, L.R.C.P., M.R.C.S., of a son.  
**CHETWOOD.**—April 12, the wife of William Chetwood, M.R.C.S.Eng., of 10 King Street, Finsbury Square, of a daughter.  
**RUSHBROOK.**—April 15, at 145 Seven Sisters Road, Holloway, Mrs. Henry George Rushbrook, L.K.Q.C.P.I. and L.M., of a daughter.  
**RYAN.**—April 11, at Emily House, Tipperary, Mary, the wife of Charles E. Ryan, M.D., of a daughter.

Marriages.

**MARSH-GETHING.**—April 12, at St. Woolos Church, Newport, Mon., Octavius E. Bulwer Marsh, M.R.C.S.Eng., L.R.C.P., of Winterbourne, Gloucestershire, to Clara, youngest daughter of Robert Gething, Esq., of Newport, Mon.

Deaths.

**ABBOTT.**—April 11, at his residence, 7 Duncairn Terrace, Bray, Richard Theophilus Abbott, M.D., L.R.C.S.I., Surgeon-Major Her Majesty's Indian Army.  
**CRELLIN.**—April 8, at Parkside, Richmond, Surrey, Horatio Nelson Crellin, M.R.C.S.E., aged 82.  
**CURTIS.**—April 10, at Fyning Cottage, Petersfield, Hants, Nellie, the dearly-loved wife of Collins Curtis, M.R.C.S.E., and L.S.A.  
**FORBES.**—April 10, at St. John's Road, Jersey, Frances Mary, wife of John Forbes, Esq., M.R.C.P., F.R.C.S., retired Medical Department H.M. Indian Army, aged 57.  
**HULKE.**—April 10, suddenly, at Admiralty House, Deal, Frederick Thomas Hulke, M.B., J.P., aged 47.  
**STOKES.**—April 8, at Mullingar, Gabriel Stokes, M.D., F.R.C.S.I., in his 74th year.  
**WATCHORN.**—April 12, at Sandfield House, Nottingham, Isaac Watchorn, M.D., aged 48.

### THE LUMLEIAN LECTURES ON BRIGHT'S DISEASE.

Delivered before the Royal College of Physicians.

By REGINALD SOUTHEY, M.D. Oxon., F.R.C.P..

Physician and Lecturer on Clinical and Forensic Medicine at St. Bartholomew's Hospital.

#### LECTURE II.—Abstract.

PURSuing the historical survey of his subject, the lecturer referred to Rosenstein's work on "Kidney Disease," published in 1863. Rosenstein, like Frerichs, regarded Bright's disease as one essentially uniform pathological process, encountered in various stages; the kidneys at death presenting appearances according to the stage to which the affection had progressed. "Diffuse nephritis" was Rosenstein's name for the condition in which all the renal elements were involved; but his classification of diseases separates Bright's from the various renal affections, of which albuminuria is a sign. Following Frerichs, the work is a valuable continuation of his labours, and in reference to symptomatology, is especially admirable. In 1860-61, Dr. Dickinson published two papers in which he described Bright's disease as "tubular," and "inter-tubular," and in 1865, Dr. Wm. Roberts, in his "Practical Treatise on Renal Disease," recognised also two terms, viz., "acute" and "chronic." His "acute" form is the equivalent of the older inflammatory dropsy, of Johnson's desquamative nephritis, of Frerichs's first stage, Virchow's parenchymatous nephritis, Rosenstein's acute diffuse nephritis, and Dickinson's acute tubular disease. He recognises three chronic types of Bright's disease; (1) large white kidneys, lapsed acute cases; (2) cases chronic from the beginning, red granular contracting kidney; (3) lardaceous or amyloid kidneys. In 1868 Dr. Grainger Stewart's "Practical Treatise on Bright's Disease," made its first appearance. In it the author accurately distinguishes between that secondary

atrophy, with coarse granulation, which follows in some protracted subacute forms of tubal or parenchymatous nephritis, in which the renal epithelium has been destroyed, and subject to fatty degeneration, with only relative increase of interstitial tissue, and the primary insidious cirrhotic atrophy of the kidney in which the interstitial tissue is absolutely increased in quantity by active hyperplasia. In 1869 the nomenclature committee of the Royal College of Physicians decided that, in future, Bright's disease should be distinguished as (a) acute, and (b) chronic, the former being used to indicate acute renal dropsy, as after scarlatina, the second including three subdivisions of granular, fatty, and lardaceous kidney. In 1870, however, after minute, histological investigation of the facts attending the disease, Klebs and Axel Key pronounced the opinion that the acute nephritis, successional to acute febrile attacks, was different in character from Virchow's or Rosenstein's acute diffuse nephritis. These conclusions were founded on the discovery that the same microscopic elements of the kidney structure were not affected in both these conditions; in post-scarlatinal nephritis the blood in the intertubular capillaries is brought to a standstill, owing to obliteration of the capillary tuft of the glomerules by swelled connective tissue corpuscles around them. There may be subsequent degeneration in the renal tubules, but the consequences of arrest of the blood current suffices to bring about all the symptoms commonly observed in such cases. These views have received abundant confirmation at the hands of Kelsch, Alf. Meyer, of New York, and Cohnheim. The views of Kelsch, published in 1874, favour the separation of congested kidney from nephritis Brightica, and confirm the opinion that there are true interstitial changes involved in post-scarlatinal nephritis. This commences, he says, by the deposition of "embryonal cells," and multiplication of muscular cell tissue in and around the glomeruli. The renal epithelium changes he regards as wholly secondary, and sequential to impeded supply of nutritive fluid. He asserts that general swelling of the organ marks the period of embryonal tissue growth, which terminates in fibrillation of the connective tissue and atrophy. Bright's disease, and interstitial nephritis are synonymous to him.

Charcot who, in 1874, issued "Legons sur les Maladies du Foie et des Reins," follows the dual hypothesis of Grainger Stewart, Johnson and Dickinson, regarding the small, red, granular kidney, as altogether different from white kidney. In 1875, Lancereaux published a treatise on the kidneys in the great French Medical Encyclopædia; in it a careful and minute description of the morbid anatomy of Bright's disease is given, and the whole question of controversy gone through. In the same year came out also Bartel's great work in Ziemssen's "Handbuch," the chief value of which is derived from its author's clinical experience. The distinctions he draws between various types of renal disease must be universally accepted; they include five stages as follows: 1. Hyperæmic changes of the kidney, active and passive. 2. Ischæmic, or blood-stasis changes, of which the choleraic kidney serves as an example. 3. Parenchymatous inflammation of two kinds; (a) acute, which may become chronic; (b) chronic from the outset. 4. Interstitial connective indurative changes, or renal cirrhosis, the origin of which Bartel cannot explain, although he rejects Gull and Sutton's, with other theories. 5. Amyloid degeneration. The great value of the work is, in the masterly way in which the clinical features of various forms of disease are pointed out, and the chapter on uræmia is especially remarkable as the best description of the condition in any language. Bamberger's very remarkable article on "Bright's Disease, and its Relation to other Diseases" appeared in 1879; in it distinctions are drawn between the large white, contracting white, and small red granular kidneys, and three forms of morbus Brightii founded on them, viz., acute, chronic, and renal atrophy. The difficulty of classifying all post-mortem appearances under separate heads is pointed out, and corroboration afforded of Virchow's assertion that, after death we encounter kidneys in which parenchymatous, interstitial, and amyloid changes are so intermixed that it is impossible to name the prevailing condition. Aufrecht had previously, 1878, proved the power of obstructed urinary outflow to set up both parenchymatous and interstitial nephritis, according as the obstruction had been temporary or prolonged. Bamberger's observations, however, were unable to separate the large white from the small red kidney; anatomical and ætiological considerations combining to confirm Kleb's views, rather to the effect that glomerular interstitial hyperplasia was probably the starting point of the changes which culminated in parenchymatous degeneration. Clinical experience led him to conclude that, though two distinct types of disease might exist, mixed forms were also met with, and rendered diagnosis of the utmost difficulty. This authority consequently holds the question to be an open one as to unity or dualism in Bright's disease, and temporarily classifies his cases as primary or self-initiated, and as secondary, occurring in the same body with other and profound important changes, these two divisions differing not so much in feature and anatomical fact, as in interpretation and prognosis. The primary are typical cases, in 42.05 per cent. of which the heart had undergone hypertrophy. This organ was affected directly, in 3.3 per cent. only of secondary cases. Of 807 cases of the primary disease, 67 were acute in commencement and course; 357 were entirely chronic; and 383 lived on to renal atrophy. The greatest proportion of acute to chronic cases, 54 to 13, occurred between the ages of 20 and 40; between 40 and 60 the chronic cases preponderated, 214 to 143; while between 50 and 70 the large proportion were cases of atrophic kidneys. Bamberger is able to group the provoking causes of secondary Bright's disease, and gives them under three heads, as 1, poisonous substances, e.g., phosphorus, lead, alcohol, ague, infectious fevers, pus, or contaminating principles in the blood, in eliminating which the kidney becomes damaged; 2, disordered circulation, depending on many causes, as valvular lesions, emphysema, and cirrhosis of the lungs, curvatures of the spine; and 3, obstruction of the urinary outlet, as shown by Aufrecht's

experiments in tying the ureters, the abnormal tension of urine confined in the kidneys setting up extensive pathological changes.

Carl Weigert attempted in 1874 to settle the vexed question of the unity or multiformity of Bright's disease on anatomical grounds, with the effect of bringing prominently out the fact that it is impossible to draw a hard and fast line between parenchymatous and interstitial nephritis. Even in acute nephritis patches of interstitial deposit are always encountered, and such changes alone, as Klebs says, deserve the name of nephritis. They naturally vary in extent with the severity of the affection, and in extreme cases will result in extensive degeneration. These changes, too, are common to the largest white and the smallest red kidney, so that the difference between them is one of degree rather than of kind. The resulting phenomena vary accordingly as the nutritional changes affect large or limited tracts; in the parts where secretion is proceeding, the secreting structures shrink and atrophy. The changes in the epithelium in chronic Bright's disease, this authority views as secondary to interstitial changes, by which the circulation through the glomerules is modified, being far more often those of atrophy than of active proliferation, though nuclear growths are found in parts extending into the interior of the tubes. Tubules filled with fatty contents he describes as very exceptional. No one can doubt the close relation between the changes in the tubes and interference with their blood supply, however brought about; but even Weigert fails to explain the diversity of results set up apparently by the same causes. He imagines the interstitial change is due always to some primary irritation, and that the tubal changes are always secondary, ascribing the death of the renal cells to starvation, and not to strangulation by the interstitial growth. The common features of the pathological changes attending the formation of large white contracting, and small red granular kidney, can only be studied by comparison of long-standing chronic cases together; and it is true that, excluding obviously acute changes, there is in renal disease no such histological or pathological difference as justifies the separation of the two forms of kidney. Advocates of dualism overlook the midway forms, the large red kidneys, and the small white ones. The difference of colour is discussed by Weigert, whiteness being due to anæmia, yellowness and opacity to fatty degeneration; anæmia being produced by interstitial œdema, which aids in its determination both by rendering the capsule lax, and by separating the blood cells further from the renal epithelium, and just as it whitens the skin, so also does it the kidney by relatively increasing its bulk, and separating its capillary meshworks more widely than normal. Sudden blood stasis, as occurs in cholera, septic poisoning, &c., by cutting off oxygen, through arresting the passage of red corpuscles, may lead to rapid fatty degeneration of renal cells, and in such circumstances there will be but little œdema, and still much pallor from anæmia and accumulated fat in the tubes. Also a fatty kidney may not look anæmic owing to its venous radicles being highly charged with blood.

The greatest amount of œdema of the organ is found in the white mottled kidney of about three or four months' duration, when time enough has elapsed for the establishment of some hypertrophy of the heart, and the kidney is both very anæmic and fattily degenerated in its cortical portion, and the circulation is by œdema and interstitial hyperplasia most of all impeded. When the hypertrophy of the heart compensates the circulatory obstacle more, the circulation through the least diseased parts becomes easier, and a great contrast is presented between the red and the white parts, which gives the organ its mottled aspect.

Cardiac hypertrophy compensates deficient blood supply, and overcomes anæmia to some extent in the more insidious and slowly progressing cases of interstitial disease, and hence, too, in such cases, fat may not be abundantly found, although the organ may become

rapidly fatty following sudden failure of the heart's force. Weigert, while admitting how much there is pathologically common to large white and small red kidney, does not think one is likely to become the other. He thus groups Bright's disease:—

**FIRST GROUP, ACUTE NEPHRITIS.**—*Anatomical features:* Small cellular interstitial growths; some small scattered hæmorrhages. *Clinical phenomena:* Scanty urine, with abundant albumen and white and red blood-cells in it; casts, generally œdema; no hypertrophy of the heart.

**SECOND GROUP, SUBCHRONIC OR CHRONIC HÆMORRHAGIC NEPHRITIS.**—*Anatomical features:* Much interstitial increase of connective tissue thickened, and contracted Malpighian capsules; endarteritis obliterans; no contraction of the entire kidney.

**THIRD GROUP, MORE CHRONIC NEPHRITIS.**—Noticeable naked-eye granular contraction of portions of the organ, besides other larger portions of the kidney in which healthy parenchyma is preserved. *Clinical phenomena:* Hypertrophy of the heart; varying amounts of anasarca and of albumen in the urine, according to the amount of urinary water excreted.

**FOURTH GROUP, MOST CHRONIC NEPHRITIS: GRANULAR ATROPHY.**—*Anatomical features:* Kidney much contracted; very little parenchyma maintained in integrity; the granular interstitial growths have extended into each other. *Clinical features:* Abundant urine scanty albumen; no anasarca; considerable hypertrophy of the heart.

Groups two and three include mixed red and white mottled kidneys, the first being chiefly large and red-gray. The fourth comprehends atrophied kidneys, non-uniform in colour, red or gray. Amyloid complications chiefly affect groups two and three. While insisting on the points common to various forms of chronic renal degeneration, and the gross distinctions between interstitial and glandular inter-tubal and intra-tubal increase of material, &c., Weigert compels us to revert somewhat to the original views of Bright, Reinhardt, and Frerichs, and accept the fact that interstitial new growth—now more rapidly, now more gradually progressing—is the fundamental pathological principle of the whole disease; and this is essentially inflammatory in nature. He proves the old conception of Bright's disease was not wrong, which explained it as one uniform inflammatory change, prolonged through various stages, complicated by secondary compensative hypertrophies, both in the sounder parts of the organ itself and in the heart, and produced by Nature in her effort to repair the damage done. He does not say that the one form becomes the other, but that there are midway forms between the large white and the red atrophied kidney, with anatomical features common to both; and the inference which he draws is quite justified by the facts, that the distinction between them is one of degree, not of kind, and that it is impossible to fix a definite line.

Cohnheim supports these views, 1880. He describes acute Bright's disease as that which first appears, or glomerular nephritis, and whether the alteration be sudden or gradual constitutes the fact of ultimate importance. Acute sudden cases die or recover; gradual or extensive ones slowly progress to more or less extensive interstitial new growth of connective tissue, and pass to greater or less contraction of the secretory structures. Contracted kidneys need never have been swollen and white, only a large kidney indicates probably recent mischief; a small contracted red one points to a long continuance of disease.

Experiments on animals by tying the renal arteries, experiments by disease on man, as in cholera, epilepsy, eclampsia parturientium, tetanus, when spasm of small arteries may lead to complete ischæmia in these organs and total temporary arrest of circulation through the kidneys, illustrate the processes of disease, and make it comprehensible. Some irritant in the blood circulating through the tufts stirs up the strife; as we can notice its acting suddenly and acutely, so we can imagine its non-

continuous or intermittent action, according as particular irritants accumulate in the blood; or, although only slightly at any one time, persistently and progressively increasing as the blood deteriorates in quality. We find illustrations of the persistent blood-irritants damaging and inflaming capillaries, in gout, syphilis, malaria, in poisons which act remittingly, in lead, alcohol, and in the effects of burns and local inflammation of the skin; products of tissue-metamorphosis, suddenly thrown into the circulation, either blocking the glomerular tufts or inflaming them.

Stagnation of the blood-current, and impurity or special impropriety of the blood, induce the epithelial and interstitial changes which progress, unequally certainly in different forms of disease, but *pari passu*, and together constitute Bright's disease. As the contents of the tubes waste, so these atrophy and contract, and their room is filled up and even overfilled by interstitial increase or growth. Then the elevated parts of the kidney become imperfectly vascular, anæmic, and grey, and represent the parts in which interstitial tissue-growth has overwhelmed secretory structures and capillaries; while the sunken parts are red, and represent capillary net-works permeating atrophied and shrunken tubes.

The relation borne to each other of the varying forms of Bright's disease is that point remaining to be definitely settled. It is now pretty generally allowed that the hyperæmic kidney, the large red grey kidney of acute parenchymatous nephritis, becomes the large white anæmic and fatty organ; and further, that this swollen, and at first smooth-surfaced, kidney does become mottled on section, uneven and coarsely granular upon its surface, and that it toughens, in part contracts, and in part atrophies and becomes smaller (although there is little agreement of authorities upon its ever coming in any way to resemble the atrophic finely granular small red kidney). Further, the tissue-changes by which this form of white granular kidney is brought about are confessedly inflammatory from first to last. This small red granular kidney, however, is by a large majority of trustworthy guides—Dr. Johnson, Traube, G. Stewart, Gull and Sutton, Kelsch, Bartels, Charcot, Rendu—held to be a distinct form of disease. Why? Mainly because the tissue-changes by which it is surmised to have been brought about are presumed to have been non-inflammatory. The cause of the change is pleaded to have been, from first to last, an interstitial or matrix tissue overgrowth, strangling the Malpighian bodies and blood-vessels, starving the renal cells, and inducing an atrophy of the secreting tubules.

There are, however, as Dr. Wilks formerly contended, a vast number of intermediate forms between the two typical varieties, and this is a strong argument in favour of the doctrine of one Bright's disease.

The pathologist has traced the two forms from the commencement; in large white kidney they declare the epitheloid lining of the glomeruli swells up, its nuclei multiply, squeeze up the capillary tufts and cut off the blood supplies; in the small red granular kidney, interstitial new growth takes place within and without the Malpighian bodies, gradually interfering with the current of the blood through the tufts, the organ being only preserved for a time by the establishment of short collateral channels.

The issue in each individual case, then, appears to turn upon the following things:—1. Whether the circulation through the organ is suddenly checked, or very gradually altered in its direction. 2. Whether the matrix tissue and the intertubular spaces are or are not soddened by dropsical effusion, 3. Whether the capsule of the organ is gradually thickened by sub-inflammatory fibrous growth, and resists the blood-pressure or yields to it—a factor of no small importance towards the quickening or slackening of the blood current through the organ. 4. The amount of blood circulation still feasible through the glomeruli; enough to maintain the renal cells at a low rate of function; enough to secure parenchymatous or glan-

dulous swelling; enough to provide for some inflammatory exudation or the development between the tubes and capillaries of a low embryonal form of nuclear tissue. 5. The maintenance or failure of the blood pressure, upon the transudation or not of urinary water, and so upon the blocking up or maintained patency of the lower excretory system of urine tubes. 6. The establishment or not of a collateral blood circuit, the vasa afferentia passing directly into vasa efferentia without going through a first capillarisation; the lowest tiers of Malpighian tufts becoming, or not, greatly hypertrophied; the sluices of the vasa recta by direct arterial conduits being employed. 7. The general health of the individual, and the capacity of his heart to become hypertrophied.

### NOTES ON OSTEOTOMY. (a)

By EDWARD H. BENNETT.

Professor of Surgery in the School of Physic, and Surgeon to Sir Patrick Dun's Hospital.

THE notes on osteotomy, which I now submit to the Surgical Society, relate to one form only of the operation, antiseptic osteotomy, with open wound; the operation of Volkmann and Macewen.

I need not trouble the Society with any historical account of the operation, which, in the last six years, has proved so eminently successful, as well in the hands of its authors, as in those of many other operators. In this city the field for practice of this operation is greatly restricted, because rickets, though not absent, is sufficiently infrequent to prevent any of us from aspiring, no matter what our opportunities may be, to records of operations by the hundred. Macewen records his own as the experience of 330 cases, all apparently of rickets.

I think that every year we see more of rickets; certainly we see, now-a-days, many more cases than occurred twenty years ago, whether the Vartry water be to blame or not. I hope the day may be very remote when we shall attempt to rival Glasgow in this matter.

I have to record notes of operations by this method on but three patients, all performed this season. Although the number is small, the variety of the conditions treated add interest to the record. One is a typical case of Macewen's operation for rickety deformity of the legs; the second, an operation undertaken for relief of deformity of the elbow; the third, the section of the thigh bone for mal-union of a fracture below the trochanters. This last case is of most interest in consequence of the great risk attending any compound fracture of the femur in this position. As these cases were all under treatment at the same time, and their respective dates overlap, I may take them in the order simplest for description.

No. 1.—A little boy, *æt.* 4½, was admitted to the children's ward of Sir Patrick Dun's Hospital on 15th October, 1880, suffering from extreme deformities of the legs, the result of rickets. He could get about with difficulty, and his limbs were curved most extremely above the ankles. He was well-nourished and florid, and although the curves of his bones daily attracted more and more attention from his parents, and, for all I could tell, might be still increasing, he appeared to have passed through the active stages of the disease.

Anxious to test this question, I kept him under treatment, and in bed for some time, with the result that he fattened rapidly, and his limbs remained without change.

His case presents some features of interest as a marked example of rickets affecting one child of a family, the parents and the other children being perfectly free from rickets, or any allied disease. There are two children older, and two younger. All alike reared at the breast, and suckled for a year and a quarter each. He showed the first sign of ailment when a little over a year and a quarter old, and never walked until three years old. At

this time he continued weakly, and his limbs began to get crooked.

On Dec. 2nd, 1880, finding no improvement from milder treatment, I divided the greater part of the thickness of the tibia of the right leg with Macewen's osteotome, removing from the convexity of the curve a wedge-shaped piece of bone, the base of the wedge being nearly ¼ inch. I then fractured the remaining portion of the bone, and also the fibula, and straightened the limb. The operation was performed with strict antiseptic precautions, and afterwards the limb, dressed in carbolic gauze, was kept supported by two ordinary lateral wooden splints. A slight venous hemorrhage occurred after the child was placed in bed, and was arrested by flexing the limb, which had been placed in the extended position. The child was sick from the effects of ether, and at 9 p.m. showed a temperature of 99·5°; the next day the temperature was, in the morning, 99·2°; in the evening, 99°. The next morning it was normal, and remained so during the remainder of the treatment. In three weeks the wound was healed, there never having been any suppuration. The limb was dressed in all five times, being placed in a plaster bandage as soon as the healing of the wound was complete.

On 27th January, the child having been, for some time, able to get about the ward without any support on the right limb, I operated on the left also. As seen in the cast, this limb was less deformed than its fellow, and might, perhaps, have been left to the chance of becoming straighter, as growth advanced, had not the increase in length of the more curved limb required, that I should attempt to bring both to the same length, as nearly as possible, by similar treatment. The progress of the operation, and the subsequent treatment was, in all respects, similar to the first, only that no bleeding occurred, and the dressings were only four in all. The temperature was raised by an attack of swelling of the parotid and submaxillary glands, probably mild mumps, which occurred on the day of the operation, not being noticed until the evening; this, in no way, affected the progress of the case. On Feb. 19th, less than four weeks after the operation, the wound having been healed some days, the limb was put in a plaster bandage, and the child was allowed to get out of bed. No further record of this case is necessary, the results being evident in the casts, except it be to note that the right limb is still a shade the longer of the two.

CASE II.—A healthy girl, *æt.* 11, was admitted for treatment of a stiff elbow. When two years old she had a fall, which fractured the humerus at its lower end, the fracture involving the joint. An elbow, fixed at a right angle, with free mobility of the radius in the movements of supination and pronation, was the result. The ulna was found to be firmly ankylosed to the humerus. The triceps exhibited but little action under the galvanic current, and only in the upper part of its long head. The brachialis anticus, too, appeared to be powerless from long disease. Under these circumstances, I could not recommend an excision of the joint, as the result would undoubtedly be the substitution of a forearm, hanging like the free limb of a flail, for one fixed at a right angle. Forcible extension of the fixed joint appeared equally contraindicated, as the condition of ankylosis appeared to be a true osseous union of the ulna and humerus. (This specimen exhibits exactly the condition which was present). As the parents were urgent that I should attempt some treatment, I considered that an osteotomy, so arranged as to divide the union of the ulna and humerus, was the safest, indeed, the only practicable treatment. This, I performed with facility, by a limited incision between the ulnar nerve and the triceps tendon. I divided the union between the ulna and the trochlea of the humerus, carrying the blade of a curved osteotome across to the outer side of the olecranon. When this section was made, I was able, by a little force, without any further section, to extend the forearm. Having moved it freely to and fro, I dressed the limb, placing it

(a) Read before the Surgical Society of Ireland,

in a position close to extension. I kept up a guarded passive motion during the first three weeks, waiting for most active movements until the wound had healed. As in the previous case, the wound healed without suppuration in this time, and I then used more free and repeated passive motion, flexing the elbow to the extreme, and extending it almost straight. But these movements were painful to the child, and she resisted them so, that I had to use ether more than once to execute them. The muscles gave me no help; I could fix the limb extended on a splint, but the position could not be maintained, as the sole muscular action tended to place the limb in its original angle, and keep it there. After protracted efforts, I was forced to allow the limb to remain flexed, for it threatened, if kept extended, to become fixed in a useless position. This case is, then, so far as establishing a free motion of the joint, a failure; but as an osteotomy, it was attended with no bad result. The girl left hospital a short time since with an arm no worse than before; the radial movements unimpaired, certainly submitted to much less risk than she would have been by excision, or by forced extension of the joint.

**CASE III.**—The subject of this case is a Nova Scotian sailor, *æt.* 32. On 22nd June, 1880, in the pitch of the sea off Cape Horn, he fell from the upper topsail yard to the deck, breaking his fall by striking the rail of the ship. The blow against the rail broke his thigh a little below the trochanter (four inches from the summit of the great trochanters). For fourteen days he could not speak from the effects of the fall on his chest and head. Then on his improving, the limb was supported by a long splint applied by the captain. On 20th September (three months, less two days), he arrived at Liverpool, where he had surgical advice for the first time. Leaving Liverpool, he crossed to Dublin, and on October 14th, after some three weeks stay in Dublin, he was admitted to Sir Patrick Dunn's Hospital.

He was able to get about on crutches, and could just touch the ground with the great toe of the left limb. His thigh was greatly deformed by a sharp outward projection of the bone at the seat of fracture below the great trochanter, while the obliquity of the lower fragment was such as to render the limb absolutely useless. The shortening measured with the greatest exactness, was a shade below  $2\frac{1}{2}$  inches; well over  $2\frac{1}{4}$ .

The fracture, as far as the details could be made out in the mass of callus which united it, was nearly transverse in direction, and the lower fragment was placed resting at an angle of  $115^\circ$ , against the inner side of the upper fragment. The union was quite solid. The lower segment of the thigh was wasted, slightly oedematous at the outer side above the knee, and the portion of the shaft of the bone, forming the lower fragment, was thickened by a chronic osteitis. The man was pallid and thin, and suffered from irregular attacks of intermittent fever, which he had contracted before the injury. From this he had suffered much during his voyage to Liverpool, and for it had taken large doses of quinine while on board. Two days after his admission he had a sharp rigor, followed by a sweat, and several such in the following fortnight.

After consultation with my colleagues and Mr. Colles, I resolved to attempt the section through the seat of fracture with the osteotome. As no other proceeding offered any prospect of success, the refracture of the bone by screw pressure, after the method of Bosch, so successfully accomplished in Mr. Butcher's case, appeared impossible, as the seat of fracture was so high, as to prevent the application of sufficient force to the upper fragment. Nothing could be expected to be obtained by gradual pressure or extension.

Accordingly, on Nov. 4th, 1880, I arranged the patient on the operation table, so that, at will, I could make traction on the thigh with the dislocation pullies. With all antiseptic precautions, I made an incision to the bone, of size sufficient to admit the full-sized osteotome guided by my finger. I directed the incision in the bone, so as to bisect the salient angle of the fracture. At first the

section went readily enough, and I cut through the external part of the upper fragment rapidly; but from this cut I found the difficulty ever increasing, the bone more dense, and the depth of the section constantly extending in width, antero-posteriorly. To be able to work the osteotome, I was obliged to clear away the sides of the section a little, and I found the antero-posterior depth of the bone and callus required full three separate incisions of the osteotome to divide it. I worked away, leaving the posterior parts to be divided last. Here I met the *linea aspera* twice, and cut it through the second time with much anxiety, for the vascular relations of the posterior surface of lower fragment were such that a small error might spoil everything, should I fall foul of the *profunda femoris*, or one of its chief branches. At last, to satisfy myself of the safety of the edge, I made way with a probe-pointed knife for my left fore-finger, and carried it as far as I could reach behind the bone. Being so confident of safety, I cut the last resisting piece of bone by rigorous use of the mallet. As I cut the last piece the pullies were brought quietly into action, and I had the satisfaction of seeing the segments of the bone swing fairly into place, and as the strain was relaxed, rest in place without tendency to shift. From this time on we had no tendency to changing of position, except a slight inclination of the lower fragment to rotate on its axis inwards, so as to turn the toe in. My patient was on the table fully an hour and a-half, and had, of necessity, a full dose of ether. I placed the limb, supported by sand bags, and a Liston splint, bracketted opposite the wound, so as to admit of change of the dressings without disturbing the limb.

The wound remained aseptic, and, as we might fairly expect after an hour's hammering and fingering of a wound, moderate suppuration occurred. The temperature reached  $103^\circ$  on the fourth day, and on the sixth day was normal in the morning, rising in the evening to  $100^\circ$ ; and so the case progressed, until on the 17th November, we ceased to record the temperature, as it was, for some days, without any elevation worth noting. Although threatened with the intermittent fever at times, the case progressed without any active treatment internally, beyond saline draughts, and a few draughts of chloral hydrate. In four weeks I found, in spite of a limited local suppuration, that union had progressed, so that I was able to put the limb in plaster of Paris, keeping a window open over the wound. In the sixth week the patient was able to sit up, and shortly after got on crutches. (22nd December). He has been to the Convalescent Home at Blackrock lately, and on Wednesday walked with a stick, and a boot, with a thick sole on the left limb, to the top of Mr. Chancellor's studio in Sackville Street, to have this photograph executed. His limb is just an inch shorter than its fellow; he has a tendency to turn the toe inwards, as he walks without any help of a stick, and he can bear his weight on the left limb alone, if he just touches a support with his finger. His knee-joint, stiff when he came under my care, is a trouble still, but daily becomes more supple; there is a little opening, which still gives exit to small pieces of bone, at first, mere chips, cut on both sides of the osteotome; latterly, a few bits from the faces of the sections, which have exfoliated, clean out on one side, marked by Howship's lacunæ on the opposite.

Such is the progress of this case, which, I think, proves that we may bring osteotomy, with antiseptic precautions to bear on conditions which we might not dare to treat by older methods. I know that operation for the relief of this particular case was declined, both in Liverpool, and in this city, by surgeons very familiar with the surgery of fractures. Shortening in the method, which alone I could apply, was inevitable, but I think it has been a minimum, while the man has gained  $1\frac{1}{2}$  inch on his condition previous to operation. I hope that I have not wearied the Society with details of these cases, all comparatively novel in this city, and one of them, at least, far from facile in its execution, and entailing risks of the highest gravity, both during its execution, and in its subsequent treatment. I believe that the progress of this artificial compound frac

ture of the femur, in spite of the occurrence of a suppuration limited to the region of the wound, may be regarded as more than of a simple than a compound fracture, seeing that in little more than six weeks union has been obtained, and the patient has been able to move with freedom within two months.

### A CASE OF "UNTYPIC" PNEUMONIA.

By BERNARD KELLY, M.D.

ALTHOUGH examples of latent pneumonia in children, by reason, we may presume, of their great susceptibility, and highly nervous organisation, are sufficiently common in general practice, the same, however, cannot be said of adults, judging from the very few instances on record, if indeed, such instances may be taken as a fair criterion of their actual paucity, and not as an indirect and negative evidence of probable errors of diagnosis. It was, therefore, with much pleasure that I have perused the very interesting notes of two such cases recently published in the *Medical Press*. But since the term *untypic* seems likely to supersede that of *latent* (from the fact that most, if not all, of the rational signs of the disease are masked or modified by the co-existence of grave cerebral and constitutional symptoms) it is important that too much significance and weight be not attached to a new nomenclature; but that we should regard the disease as still the same, both in its physical aspects, and its anatomical and pathological characters. Too much credit cannot be awarded Dr. Tyson for the admirable manner in which he has brought the subject under the prominent notice of the profession. And as the question is not likely to suffer in interest from the accumulation of examples illustrative of it, I have been induced to exhume the notes of a case that occurred in my practice some fourteen years ago, when residing in New York, with the hope that their native nakedness may be no impediment to their withstanding the light of day.

M. D., *æt.* 40, Irish, temperament neuro-sanguine, naturally of a pale, sallow complexion, but of strong, wiry constitution; shoemaker, married; took to his bed on January 4th, 1867. Saw him two days subsequently. He complained of pains and general malaise; and had been unable to sleep from the beginning of his illness, a circumstance which caused himself and family no little anxiety and alarm. On examination, found the pulse ranging from 108 to 112 in the minute; great fever and thirst, the tongue dry and coated. Had had delirium towards night, during which he spoke incoherently, and raved incessantly. The urine was moderately abundant, but high-coloured, and let fall, on cooling, a lateritious deposit. Nothing remarkable about the pupils. At first suspecting the case to be one of typhoid, I examined the body for the characteristic eruption, but in vain. Neither were there tenderness; or gurgling in the right iliac fossa; nor had he had diarrhoea, or epistaxis. On auscultating the chest, I was surprised to find a well-marked crepitant rale, accompanied with faint friction-sound at the left side, extending backwards to the spine. My astonishment was all the greater from the fact that he had no cough, and experienced no local pain, nor dyspnoea. This I accounted for through the cerebral excitement which completely overcast all other symptoms, and which, had the examination been less careful and thorough, might easily have misled me in my diagnosis. Ordered the following—

R Hyd. sub. mur., ʒj;  
Pulv. jalap., ʒij;  
Ext. hyoscyami, g xij;  
Pulv. aromat., ʒss;  
M. Ft. chat, vi.

A powder to be given every three hours.

January 7th, 1867.—Had slept well, and had taken five of the powders in the meantime. Had had three or four abundant evacuations. Less fever and thirst. Pulse 80. His condition, on the whole, much improved; but now,

for the first time, complained of sharp pleurodynia, accompanied with cough and rusty sputa. Ordered—

R Hyd. sub. mur., gr. x;  
Pulv. jalap., ʒss;  
Ext. hyos., gr. viij;  
Pulv. aromat., ʒj.

M. Ft. chat, vi.

One to be taken as before. The patient to drink freely of beef-tea and toast-water.

8th.—Had had a restless night, owing to a severe pain in the side, and harassing cough. The tongue thickly coated; the gums covered with a white, pasty sordes, and somewhat swollen and spongy. No marked factor of the breath, nor tenderness of the mouth indicative of incipient pytalism. The mental faculties were seriously disturbed, the patient labouring under the delusion that persons were engaged in torturing him in every conceivable manner. The pulse had fallen to 60, and was very soft and compressible, but regular in rhythm. The sputum mucopurulent, and tinged with dark, grumous blood. The urine very abundant, comparatively clear, and free from deposit. The bowels had acted three or four times. Suspended the calomel, and prescribed—

R Liq. ammoniæ acet. (dil.), ʒiij;  
Spt. ether nit. tinct. hyos., āā ʒij;  
Vini. ipecac., ʒss. M.

A tablespoonful to be taken every three hours. Beef-tea and rum punch: the former, *ad libitum*; four ounces of the latter every four hours. Thin whey and toast-water as ordinary drinks.

9th.—Found the patient to-day much in the same condition, but with this difference: that his hallucinations were now bordering on confirmed insanity. While standing at his bedside, he had had frequent fits of laughter, and seemed much amused by an imaginary face peering at him from out of the ceiling, and more than once raised the bed-clothes, apparently in search of this mysterious figure. When interrogated, his answers were, for the moment, direct and rational; but so soon as the conversation ceased, he invariably relapsed into the same incoherent train of thought, relieved by interludes of hearty laughter. The mixture caused great nausea and vomiting during the first two or three doses, but was well borne afterwards, producing little or no sickness—resembling in this respect the tolerance induced by repeated potions of tartarised antimony. The surface of the body was moist, and of a natural temperature. The urine clear and copious. Had not slept during the night. The pulse still remaining at 60, weak and compressible. *Perga*: in usū medicinæ. A blister, 6 in. by 8, to be applied over the inflamed portion of lung. Was hastily called to see him the same evening, as his condition and symptoms had become greatly aggravated, and had alarmed the household. Examined the side, and found that the blister had well taken. The patient was perfectly ungovernable, and was with much difficulty restrained from getting out of bed, and dressing himself. Made no alteration in the treatment, but ordered the man to be closely watched during the night.

10th.—The patient had not had a single moment's sleep in the interval. Hallucinations the same, with a strong disposition to inflict injury on those around him. Prescribed—

R Quiniæ sulph., gr. xvi;  
Morphiæ sulph., gr. j;  
Acid. sulph. arom., ʒss;  
Aquæ anisi, ʒiv. M.

A tablespoonful every three hours.

I had forgotten to mention that on the previous day, even in his delirium, he complained of tenderness of the gums, and indeed of the whole buccal membrane. Ordered milk punch and beef-tea to be given freely.

11th.—Had slept soundly throughout the night; and, in composed and sane language, pronounced himself a well man. The clammy perspiration, which persisted during the two previous days, had entirely disappeared. The tongue became clean and moist; and quite a keen relish

was manifested for the beef-tea and punch. Jokes (for I must say he possessed quite a natural, if not a national, talent in this way) succeeded the delusions. Suspended the quinine mixture, and substituted the following:—

R. Pot. iodid., ʒss.;  
Tinct. opii, ʒss.;  
Syrup aurantii, tinct. cinchon. co., āā, ʒij.;  
Aqua add, ʒiv. M.

To be taken as before. Beef-tea and milk punch as usual.  
12th.—Found the patient in a deep slumber. Had slept well the whole night. Awoke after a few minutes. Spoke incoherently for a few seconds after waking, but soon recovered his mental equilibrium. The gums much swollen; the breath extremely fetid; and the whole mucous membrane of the mouth painful and inflamed. Has little or no cough; no trouble in the side; and expectorates with ease a small quantity of muco-purulent matter. Had forgotten to examine the force, frequency, &c., of the pulse. The patient had voided no urine for about twenty hours, but expressed himself quite comfortable in every other respect. Has had no evacuation from the bowels for the last three days. The previous mixture to be continued. Ten grains of the chlorate of potash, dissolved in an ounce of water, to be taken between each dose, using it at the same time as a mouth wash and gargle. Beef-tea, with boiled rice and milk punch, *ad libitum*.

13th.—The man making steady progress; salivation and fœtor of breath much diminished; gums and mouth, however, much swollen and tender. Has had two motions from the bowels. Urine normal in quantity, colour, and consistence. Pulse 64. Pergat. Changed beef-tea, of which he grew tired, for chicken broth with the meat. Towards evening of the same day was informed that he has had frequent bloody stools, with griping and tenesmus. Ordered a grain of the acetate of lead with ten minims of the tincture of opium in an ounce of mint-water every four hours.

14th.—Found the patient to-day entirely free from dysenteric symptoms. Had slept well. Pulse 68. Was told that boiled chicken had always had the effect of purging him, even when partaken of in the best of health. Interdicted all further use of the noxious delicacy, substituting the safer, though more substantial, nutriment of beef-tea, rice, and broiled steak. Under the use of quinine and the chlorate of potash, the convalescence was most rapid and satisfactory, the patient being able to resume his duties in an inconceivably short space of time.

The free and somewhat fearless manner in which I employed the calomel will not, I apprehend, meet with the unqualified approbation of many junior practitioners of the present day. But it is, I am convinced, in cases like this, untypical and anomalous, in which the matchless properties of the drug shine forth in all their efficacy. Through an ill-founded, though laudable, dread of damaging the system by energetic treatment, we not unfrequently run the risk of allowing many valuable lives to perish. Grave diseases demand grave and heroic remedies. The milder ones may be safely left to ordinary means and the resources of Nature.

Plough Road, Rotherhithe, London.

FROM diseases of the zymotic class in the large towns last week whooping-cough showed the largest proportional fatality in Manchester and Leeds; and scarlet fever in Wolverhampton. The 32 deaths referred to diphtheria included 10 in Glasgow, 9 in London, 5 in Edinburgh, and 2 in Birmingham. The highest death-rates from fever, mainly enteric, were recorded in Plymouth, Liverpool, Sheffield, and Newcastle-upon-Tyne. Small-pox caused 85 more deaths in London and its outer ring of suburban districts, one in Oldham, but not one in any of the other large towns.

## Clinical Records.

### NORTH-EASTERN HOSPITAL FOR CHILDREN.

#### *Case Simulating Congenital Disease of the Heart.*

Under the care of Dr. C. E. ARMAND SEMPLE.

ON May 14th, 1878, a little boy, æt. 2½, who had been in attendance as an out-patient for a couple of months, on account of a rather persistent cough, was found to have a mitral systolic murmur. About a month afterwards he was treated for an attack of diarrhœa. His general health not improving, a more careful inquiry was made into the history of the case, when it was elicited that he had been "dwindling away" and had had his "lips purple." He was not now cyanotic, and the hands were pallid. The child was exceedingly irritable so that it was almost impossible to examine the chest satisfactorily. A systolic murmur at the apex of the heart was, however, distinctly audible to the ears of several auscultators, amongst them, one whose name is well known and highly respected in the profession.

The child from this time forward (a period of seventeen months) continued gradually to waste, and died on December 7th, 1879. The following is an account of the post-mortem examination:—

On opening the left pleura some two or three ounces of fluid were found contained in that cavity. The pleura was greatly thickened and its costal surface united by strong bands of adhesion to the parietes of the chest and upper surface of the diaphragm.

The left lung was shrivelled and exceedingly firm and dense (chronic interstitial pneumonia), and was studded with points of broncho-pneumonia. The right lung appeared healthy.

The heart and great vessels were perfectly normal.

The glands in the mediastina were many of them greatly hypertrophied, some one and a-half to one and three-quarter inches in length and half an inch in thickness. Cutting into them gave the sensation almost of cutting into a scirrhous tumour, and to the naked eye they resembled in appearance hard adenomatous growths.

The spleen was very large and hard, having on its surface a white superficial patch about an inch in diameter.

The interest in this case centres in the fact that the physical signs, so far as it was possible to detect them, indicated cardiac mischief, presumably of congenital origin. The pallor which, although not usual in such cases, is well known to exist at times, was not, therefore, regarded as contra-indicating the diagnosis.

That the murmur existed there is no doubt, although its causation is obscure; but bearing in mind how murmurs may be produced by pressing on the lumen of a blood-vessel (and in children it is not uncommon for glands thus to press), it is not unreasonable to assume that the murmur in this case had such a causation. That the maximum intensity was in the region of the apex can scarcely be said to detract from this view for a child of such tender years. The valves lie so closely together that the localisation of murmurs is neither so easy nor so certain as in adults.

#### *Case of Diphtheria of Fauces, Palate, and Respiratory Passages—Tracheotomy—Death after Twenty Hours.*

E—A—, æt. 11 months, admitted into North-Eastern Children's Hospital February 8th, died February 9th, 1880.

*History.*—Had a "bad cold" during the previous week; worse since Thursday the 5th, being "like influenza," and accompanied by a little hoarse cough.

On Friday she lost her voice.

On Saturday she could not suck well, snuffing was very bad, but there was no dyspnoea. Slept badly that night.

On Sunday there was some dyspnoea; mouth kept open. Dyspnoea got worse during the day, and swallowing was accompanied by "fighting to get it down." Child was brought to the hospital at 11 p.m. on Sunday when the following was the condition: Marked croupy respiration, lower part of chest sucked in, pale and dusky; lips livid, from time to time struggling for breath; much turbid mucus in mouth and nostrils. It was impossible to get a view of the throat. Tracheotomy performed about 12.30.

After artificial respiration for two or three minutes child commenced to breathe through the tube and continued to do so. At 3 a.m., the note is "marked relief; some viscid mucus stained with blood in tube and coughed up; colour improved; sleeping quietly; pulse 156; two teaspoonfuls of brandy with water to be given gradually."

Note on morning of 9th—"Pulse very rapid, more than last night; a good deal of curdy mucus has been coughed up and removed from tube; tube removed twice because of whistling and some difficulty of breathing." Upon auscultation air was found to enter lungs at that time well, though there was some sucking in, and breathing was intermittent; had taken milk readily. Later in the day the child got worse, pale, and livid, lower part of chest sucked in. Died at 8 p.m.

*Post-mortem.*—Thick dirty white membrane on fauces, posterior surface of velum palati, back of epiglottis, and about cords and below cords, down to the second or third bifurcations of the air tubes. The tracheotomy wound had divided the upper rings of trachea in the middle line, just saving the lower border of a thick isthmus thyroids.

*Note.*—Mr. Stevens, of Stoke Newington Green, states that he has been recently attending a brother of the child, *æt.* 3½, who had a sore throat with patches, which took five days to clear off from the tonsils.

#### Double Renal Calculi.

A—D—, *æt.* 7, admitted into Children's Hospital December 29th, 1879; died December 31st, 1879. This patient was admitted in a very miserable and anæmic condition. The history was obscure, but it appears that the child had complained off and on for three years of pain in sides and back and occasional vomiting. The water was said to be turbid soon after standing, for the last few weeks. She had suffered from malaise for the last three weeks.

December 31st, 11 a.m.—Rigor and convulsion; urine smoky, albumen one-third. 7.30.—Had another fit, mostly on right side, and died quietly shortly afterwards.

*Post-mortem.*—Calices of both kidneys greatly distended, and all packed with stones which were very irregular in shape and size, varying from small grains up to half a kidney bean in magnitude. On the right side, where the pelvis narrowed to the ureter, a large flattened calculus was lodged, and the wall of the pelvis on one side was thinned over it. There was pus about the calculi. There was a fair amount of kidney tissue external to calices, but this did not look healthy.

## Transactions of Societies.

### CLINICAL SOCIETY OF LONDON.

FRIDAY, APRIL 22.

T. SMITH, F.R.C.S., Vice-President, in the chair.

Mr. W. G. TYSON, M.B., F.R.C.S., (Folkestone) on  
A CASE OF CROSS-LEGGED PROGRESSION.

J. W., *æt.* 67, a waggoner for many years. At the age of 14 he fell on a barn floor and injured the right leg; this accident kept him in bed for four months. He says from this time he could never straddle a horse, and always walked lame. Sixteen years ago he began to have difficulty in keeping up with his horses, his legs becoming more and more approximated; the last fifteen months he has walked cross-legged. This latter position is maintained day and night; with some force the legs can be unlocked and brought parallel, but not without causing pain. There is only the slightest movement in each hip-joint, the surrounding bone appears thickened. When he gets up in the morning, or when he starts to walk, a crackling noise is distinctly heard. Both extremities are extremely adducted and everted, the heels are far apart, and the toes close together; the legs cross one another just above the knee-joint, the right being in front. The hip-joints are the only ones at all affected in the body; both knee-joints can be fully flexed, but these are scarcely moved except in sitting or lying down. He can walk with two sticks very slowly and for a short distance, but he nearly always uses two crutches. In commencing to walk the crutches are first placed forwards, and then the body is thrown on to them, the

lower part of the spine appearing to take, in fact it really does, the place of the hip-joints, there being hardly any movement in hip or knee on either side, the body is thus raised by the crutches and swung forwards. The absence of knee-movement in progression constitutes a difference between the present case and those exhibited by Mr. Lucas, in one of which the knee-movement was considerable. The following description best explains the cross position of the limbs: in the original accident some injury to the right hip-joint occurred, and during its repair adduction of the right leg took place; this condition then would naturally account for the difficulty he had as soon as he was able to get about of sitting across a horse's back. The right hip became ankylosed, and as time went on, and the right leg became more adducted, there was a tendency for the left one to pass across to the right side in order to maintain equilibrium, and as movement in the left hip became less, so ankylosis would gradually come on here, and thus after a time both hips would become fixed; the movements lost in these joints being supplied to a great extent by a complementary movement occurring in the lower part of the spine. The cause of the cross position of the legs was discussed when Mr. Lucas brought forward his two original cases before this Society on the 22nd of October of last year, but more fully by him subsequently in a paper to the *Lancet* in the following December. The three theories mentioned in Mr. Lucas's latter communication were called (1) the adduction, (2) the gravitation, and (3) the optional, or where the leg on the same side of the injured hip is thrown on the limb of the opposite side for the purpose of rest and relief of pain. It seems to me that adduction of the limb must be the commencement of all these cases, it making no difference whether the adduction is at first produced optionally, or whether it comes on in the course of the hip-joint disease, and providing that the limb is sufficiently and permanently adducted, so as to interfere materially with progression, the other leg will naturally be passed across its fellow to keep the body in the erect position, and also as the easiest way for walking. In the commencement of these cases there is probably the usual inversion accompanying the adduction, but as soon as the patient attempts to walk this is slowly changed into eversion, as the latter position allows greater scope for the movements of the knees and ankles.

Mr. C. LUCAS said he had heard of two cases of this kind since last October, one at Brighton, the other at Tunbridge Wells. The condition was a rare one, and should be regarded as a sequence of double hip-joint disease. The original disease might be one of several different forms; thus of his own patients, one was a man in whom osteo-arthritis, and the other a boy in whom pulpy disease of the joint, initiated the pathological changes producing the cross-legged state.

Mr. HOWARD MARSH remarked that the position these patients assumed was one of adduction and fixation of both limbs. This state could not follow adduction of a single limb, else there would occur instances without number in cases of advanced hip-joint disease. He did not think ankylosis of the joint succeeded to adduction.

Mr. SMITH asked if there had been cracking in both joints, and in reply,

Mr. TYSON said it had been made out in one only.

Mr. SMITH continued, that adduction was a common consequence of advanced hip-joint disease, but that it did not lead on to the condition of cross-leggedness, which, moreover, could only be imagined as due to diseased condition of both sides at once. Mr. Lucas's patients could walk alone to some extent, but Mr. Tyson's case was quite unable to move without crutches.

Dr. WILSHIRE suggested a neurosal origin for the condition. A patient of his own having been struck on the hand by a cab-door, became subsequently the subject of ascending neuritis, the hand swelling only a little.

Mr. LUCAS wished to know if Dr. Willshire's patient progressed cross-legwise.

Mr. TYSON said the original accident inducing the disease happened so long ago he had been unable to gather more than a doubtful account of it. Ankylosis of the right hip-joint supervened on the injury. He agreed that the rare occurrence of these cases was explained by the fact that in ordinary disease adduction is only partial. The subject of his paper had been cross-legged for fifteen months only; in him all movement was from the lower part of the spine, the knees remaining fixed.

Mr. WILLIAM STOKES (Dublin) on

A CASE OF EXCISION OF THE TONGUE.

The author commenced by alluding to the change that surgical opinion has lately undergone in reference to the merits of excision of the tongue, and mentioned the views of Prof. Gross and Mr. Collis on this subject. The particulars of six cases in which the author had excised the tongue were then briefly stated, in which relief from suffering caused by enlargement of the tongue, difficulty of deglutition and articulation, discharge, and pain, was obtained in all as an immediate result of this operation. In two of the cases a considerable time—twenty-two months and eighteen months—elapsed without any recurrence of the disease; in two others three months and four months elapsed; in one the patient was lost sight of immediately after the wound healed; and in only one of the cases was an almost immediate return of the disease observable. Performing the operation at an early period of the development of this disease, if possible, before glandular complication, was strongly advocated, and Sir J. Paget's views stated as regards the small risk attending the operation. The question of unilateral or bilateral ablation was then discussed, and the advantages of the latter pointed out. The question of what is the safest and best method of excision was then considered as well as the two special dangers of the operation, hæmorrhage and septic complications. The author observed that removal of the tongue by a cutting operation is not only more liable to be followed by hæmorrhage but also by septic infection, the outcome of which latter is in a large number of cases either pulmonary gangrene or septic pneumonia. These are not observable at all to the same extent in the cases operated on by the *écraseur*. In proof of this, the statistics of Dr. Schläffer and Mr. Collis were considered, in the former of which it was found that the percentage of mortality from septic causes in the cases operated on by incision reached the startling figure of sixty and in those of Mr. Collis sixty-one. Mr. Barker's cases were also alluded to, but the number of cases (3) operated on by incision in which there were no septic consequences was not considered sufficiently large to materially affect the conclusion arrived at. The disadvantages of certain of the *écraseur* operations was then pointed out, and the author concluded by describing the method of operating he preferred: He commences by transfixing the cheek at a point corresponding to the last molar of the lower jaw and makes an incision downwards and forwards towards the angle of the mouth, terminating a few lines above it. All bleeding vessels being secured and the parts retracted, a ligature is passed through the tip of the tongue to facilitate the drawing forwards of the organ by an assistant. This being done, a straight Liston's needle, armed with a double strand of carbolised silk, is passed through the base of the tongue, at a point behind the foramen cæcum. In front of this the chain of an *écraseur* is passed round the tongue, and the organ gradually severed. This part of the operation is done very slowly, taking from thirty-five to forty-five minutes. The author never witnessed in any of his cases any secondary hæmorrhage immediate or remote. The wound in the cheek is then brought together by a few points of interrupted suture. The free ends of the strand of silk passed through the base of the tongue are then fastened temporarily by adhesive plaister to the side of the cheek or forehead. The double thread, which in the event of secondary hæmorrhage or retraction would be of much assistance in enabling the surgeon to draw forwards the base of the tongue and secure the bleeding vessels, is removed usually on the third or fourth day after the operation. The author believed that by the use of the *écraseur* employed in the manner he described, coupled with antiseptic measures during the healing of the wound, the operation is attended with little pain, with the minimum of risk as regards either primary or secondary hæmorrhage, or those septic troubles which after all cutting operations are so fruitful a means of raising the mortality attending this important operation.

Mr. HEATH believed that younger surgeons were more inclined than Dr. Stokes seemed to imagine to perform this operation, judging from the frequency with which it had been attempted recently. He wished to correct the statement attributed to him that he had witnessed extensive regeneration of the tongue, by adding that the organ had been less completely removed than he was reported to have said. On reference to notes, he found the real amount to be "more than half." He had discarded the galvanic in favour of the

wire *écraseur*, on account of the bleeding which succeeded when the former instruments were employed. He had never had occasion to incise the cheek in this operation, finding the curve of the *écraseur* sufficient help in guiding its course. He advocated unilateral operation, because, as Mr. Morratt Baker pointed out, it afforded means of free examination.

Mr. M. BAKER said he preferred the unilateral operation when that procedure enabled all the diseased tissue to be removed. He was surprised that Mr. Heath had found no need of opening the cheek. He thought that external disfigurement should not influence treatment in so grave a disease. The apparent new growth from stumps left after excision he believed due to the fact that the tongue can be brought forward to the incisor teeth as far as the foramen cæcum; when, as in a patient of Mr. Gant's, the tongue is more completely and wholly removed, articulation is almost impossible. Tracheotomy, he thought, was not often called for. Recently he had assisted in a case when it was performed on account of hæmorrhage; the urgent symptoms were relieved, but soon trouble again arose from the presence of blood in the trachea. The pharynx should be well plugged to prevent blood from running into the trachea after tracheotomy.

Mr. MACCORMAC inquired by what means Dr. Stokes had removed the diseased glands from his patient. The success of the operation he considered depended largely on the completeness with which all diseased tissue was removed.

Mr. BARKER enumerated thirty-four cases of excision of the tongue performed at University College Hospital between 1871-79. Fifty-one cases of epithelioma of tongue presented, but only thirty-four were operated on. Of this number eleven died from the consequences following operation; five deaths were from septic pneumonia, two from septicæmia, one from œdema glottidis. The galvanic *écraseur* was employed in twenty-three instances, and of these patients nine died. The wire *écraseur* was used in seven cases, with one death, due to pyæmia. The knife was the agent of excision in three cases; with one death. The galvanic *écraseur*, in consequence of these results, had been abandoned in favour of the wire instrument, with the effect of steadily reducing the mortality from operation. Mr. Barker said he had operated in all the ways described, but preferred to split the root, controlling hæmorrhage by forward pressure from behind by the finger on the lingual artery. He considered the danger of septic poisoning was less after a cutting operation than a crushing one, and he defended the prophylactic employment of tracheotomy. He had found no difficulty in plugging the pharynx with sponge in these cases.

Dr. DOUGLAS POWELL suggested that Mr. Barker had unintentionally exaggerated the deaths from septic influences. Had any other organs, in these cases, shown traces of infection? Septicæmia, he urged, was a blood disease in which various organs were affected. Plugging, in the way described, would do much to prevent the occurrence of septic conditions.

Mr. M. BAKER said he could endorse the statement made by Mr. Barker as to the ease with which the lingual artery could be controlled.

Mr. T. SMITH inquired how the wire had been applied round the tongue, since there was no account in the description of the operation of incision of the sub-lingual tissues. In almost every case of fatality after this operation there was, he observed, gangrene of the lung, due to septic bronchial pneumonia, set up by blood trickling into the lung. The galvanic *écraseur* produced a most disgusting slough, which could hardly fail to be a source of mischief.

Mr. MARSH said he had been disappointed with the result produced when he had excised the tongue by the unilateral method; deglutition and articulation were seriously impaired. The galvanic *écraseur* was, he thought, generally condemned. Mr. Barker's conclusions were not endorsed by the experiences gained at St. Bartholomew's Hospital.

Dr. COUPLAND hoped Mr. Barker would reply to Dr. Douglas Powell's remarks.

Mr. BARKER described the ways in which lung may be affected by septic influences, but this

Dr. DOUGLAS POWELL said, did not meet the question he raised, viz., whether the conditions observed did or did not indicate blood-poisoning; whether, that is, the effects were directly due to the wound products? If purely local, the remedy was ready at hand.

Mr. BARKER knew of only one case in which there was

general pyæmia; in this body there were found abscesses in the liver and kidneys. He thought there were not similar evidences in the other cases.

Dr. STOKES said Mr. Barker's reading of statistics did not much affect his general conclusions. He was surprised, however, that Mr. Barker still approved of cutting in preference to removal of the tongue by wire écraseur. He was glad to have Mr. Marsh's opinion that total removal was the more advisable procedure. He knew of a case in which a patient requested to have the half that had been left after a unilateral operation taken away. Division of the cheek was necessary, as Mr. Baker said, to enable exploration to be made. The sublingual tissues were cut in his operations, after the manner recommended by Sir James Paget.

#### SURGICAL SOCIETY OF IRELAND.

A MEETING of the Surgical Society of Ireland was held on Friday evening, March 18, 1881, in the Albert Hall, Royal College of Surgeons, Mr. COLLES, senior member of the College present, in the chair.

Mr. B. WILLS RICHARDSON, hon. sec., read the minutes of the previous meeting, which were signed.

##### EXCISION OF KNEE-JOINT.

Mr. Wm. WHEELER exhibited part of the tibia and the femur, which he had removed on the Thursday week previous, from a boy in the City of Dublin Hospital. He was about 16 years of age. There was no history of injury to the joint, but he complained of pain attacking the knee about eighteen months before. There were no sinuses, nor was there any thickening, that could be felt, of the periosteum, or along the femur. The chief pain was, as usual, in the head of the tibia. Looking at the tibia, the cartilages appeared to be tolerably healthy, and there was most disease where the ligaments were attached and along the margin of the tibia. One of the inter-condyloid notches was slightly carious. The abscess ran back into the medullary cavity of the femur. The patella, however, was perfectly healthy.

##### EXCISION OF HIP-JOINT.

Mr. A. H. CORLEY exhibited the head of a femur removed by him from a patient that morning. The patient was 38 years of age, and the disease was of a year and four months' standing. About a year and four months ago the patient had been wrestling and hurt his hip, but apparently not seriously, as he performed his ordinary work, and walked about for two months afterwards. Then the joint became swollen, stiff, and painful. Three months ago there was a large abscess surrounding the hip-joint, and the limb had all the signs of dislocation. However, for some time after his admission the abscess seemed to get smaller, but he could not say whether this was the result of its being diffused among the muscles, or was caused by absorption. At any rate, the signs of the accumulation of matter were less evident than before, and he was inclined to think that there might be ankylosis in the new position, thus rendering operative procedure unnecessary. However, for the last three weeks signs of the accumulation of matter returned, and, as the patient's health began to suffer, Mr. Corley thought it right to give him the chance that excision of the hip-joint would afford. That the patient was strumous-looking he would not say. The only affection Mr. Corley found bearing on the case was that the patient had had syphilis when much younger. The specimen showed that, but for the operative interference there would be no chance of the patient's recovery. Part of the bone taken away was eroded. It occupied a position behind the glenoid cavity, and it was denuded of the periosteum down to the great trochanter. The femur itself was diseased on the surface as far as the lesser trochanter. The acetabulum was diseased, but not very extensively. Though the surface was bare and the cartilages gone, the bone had not any of the crumbling characteristics associated with caries. The specimen was interesting as showing the amount of disease that might exist before the matter made its way externally. The abscess had never been opened, and it was the first time the pus had made its way to the surface.

##### LACERATED ANTERIOR TIBIAL ARTERY.

Mr. F. ALCOCK NIXON exhibited a remarkable case of partial laceration of the anterior tibial artery in two places,

caused by the shaft of a car passing through the interosseous space between the tibia and fibula, fracturing the latter bone, and laying open the tibio-fibular articulation. The limb, which was a very muscular one, was completely transfixed; Mr. Nixon could easily pass two fingers through it, from before backwards. The posterior tibial artery, though in the direct line of the wound, escaped intact. The superior tibio-fibular articulation suppurated, and as it communicated (as Mr. Nixon believes it does once in every seven cases) with the knee-joint, this articulation also suppurated. The veins of the limb were varicose; there were cicatrices of old ulcers. No pulsation could be detected in either limb at the tarsus. The man lost a considerable quantity of blood before admission. It was impossible to say what or how many vessels were wounded. From the direction and extent of the wound it appeared as if neither tibial could escape; owing to the laceration and distortion of the parts it was impossible to tie any vessel. Primary amputation, it was thought, would give the best chance of life. This having been declined, the wound was firmly plugged. On the sixth day there was secondary hæmorrhage, the blood coming through the posterior wound, owing to which, and the state of the limb, amputation was imperative. It was performed in the middle third of the thigh, owing to the condition of the knee-joint already alluded to. The man died from the shock of the operation, added to that produced by the primary and secondary losses of blood, his vital powers being also lowered by the suppurative fever from which he suffered. The fact of the blood coming through the wound in the calf led to the belief that it was the posterior tibial which was "sprung." The specimen, however, showed this vessel to be intact and healthy.

##### EXCISION OF ELBOW.

Dr. ASHE, on behalf of Mr. Henry Gray Croly, exhibited portion of the end of a humerus, radius, and ulna, removed for partial ankylosis from a patient in the City of Dublin Hospital. The arm was capable of complete extension, but was only partially flexed. Last Tuesday week the operation was performed, and the man is progressing favourably.

Mr. EDWARD H. BENNETT read a paper dealing with

##### CASES OF OSTEOTOMY,

which will be found on page 352.

Dr. R. L. SWAN thought the Society ought to be gratified with the record of the cases of osteotomy just read; but the field for observation in Dublin he did not think so limited as Mr. Bennett had stated. No doubt, until within a recent period rickets did not come under surgical treatment so often as at present. He believed a great many cases of curvature of the tibia would derive much benefit from gradual straightening by splints if it occurred in the middle third of the tibia, but if below the middle third a section of the bone was necessary. He had a record of twenty-nine cases, the results of not a few of which some surgeons present had witnessed. He had never removed a wedge from the tibia, but had merely made a section with the osteotome at the point of the greatest curve, applying the antiseptic treatment as perfectly as he could. Cutting the tibia at its inner and anterior aspect, he never completely divided it by the chisel, but made the section subsequently, by pressure. As the child grew older there would be a certain amount of shrinking of the limb due to the condition of the fibula. In reference to the cicatrix to which he had paid some attention he would divide it subcutaneously. He had observed that the youngest member of a family was often the subject of the disease. He had operated on five cases of deformity of both limbs, operation on both on the same day, and he had never seen bad results.

The CHAIRMAN considered it remarkable that the chisel cut the bone regularly without splintering it. Indeed, the chisel could be so guided as to cut a piece wedge-shaped, showing its superiority to the saw in those cases.

Mr. STOKES said he had had an opportunity of seeing the third of the cases Mr. Bennett had recorded, and he could bear testimony to the admirable result that had been obtained. It also spoke volumes for the great practicability of the instrument already mentioned; for one of the first things that struck him on examining the case was the enormous hypertrophy of the femur, the result of the chronic osteitis, and to be able to get through such an amount of tissue, and so successfully, with that instrument spoke a good deal for its practical utility. He himself had experience of the instrument, but only in a single case in which he operated last week—a

modification of Adams's operation. The patient had recovered from the hip disease, but with the limb in a permanently flexed position, and perfectly useless to him. He cut down on the neck of the femur, and divided it by means of the osteotome, dividing the bone with considerable facility, and getting the limb into a fairly good position. What the result of the case would be it was premature to speculate, but he could testify as to the facility with which the bone was divided by the instrument in question, and also to the interesting fact that since the operation—now nearly a week—the wound had remained perfectly aseptic, and neither the pulse nor temperature had risen beyond the normal standard. So far as could be judged there was a fair chance of the case terminating well. The operation of osteotomy was one of a class of operations the performance of which was entirely due to the introduction of antiseptics as practised by Lister. No one would dream of performing Macewen's operation, or any of those alluded to without that precaution. It was surprising how few instances there were of osteotomy involving the larger articulations. There had been some, but they were few and far between. With reference to the observation regarding the comparative infrequency of rickets in Dublin, he could endorse what Mr. Bennett said. It was surprising how few cases of rickets came under his notice—they were altogether exceptional. In reference to the operation of forcibly breaking the bones, he was under the impression that Professor Rissoli, of Bologna, was the originator of the procedure. He was himself opposed to the use of osteoclasts in such cases.

Mr. BENNETT—It was performed by Bosch, of Augsburg, in 1782.

Mr. J. K. BARTON congratulated Mr. Bennett on his paper, and on the casts with which he had illustrated it. He had himself had an opportunity of observing cases of rickets, and he could bear testimony to the way in which they turned out. Operating with the carpenter's chisel, properly tempered, he took a thin wedge out of the anterior portion of the most convex portion of the tibia. As to what state the fibula was in he had no evidence whatever; but it did not appear to require any consideration or come under notice. The fracture was easily made when the thin wedge was removed. The first two cases followed the same course as Mr. Bennett had mentioned—they rapidly healed, and the children were able to run about. But in the third case, a child three years old, on the second day after the operation a smart hæmorrhage occurred. The bone was exceptionally hard, and having with more difficulty than usual chiselled away a piece out of it, and then completed the fracture, it was quite possible the sharp edge of the bone behind might have torn into the posterior tibial artery. That case did not get on under the antiseptic treatment as well as others had done—there was subsequent suppuration and considerable delay in the healing. However, it ended favourably—the leg was straight, and the child came to have the other operated upon. In the second case Mr. Bennett said the operation of excision would have resulted in the arm being flail-like, without power. He did not see why that should be the result. Within the last six months he had a case in point. A girl came to him with her arm ankylosed, in a perfectly straight position. It lasted a year and three months, and the muscles were greatly atrophied. He performed excision, but there was no power in the muscles even after the wound had healed. Now five months after the operation power had been regained, and the patient was able to raise her arm to the back of her head, and to her mouth, &c. Thus, by the removal of a single piece of bone from the humerus and ulna, to allow of free action, a useful limb might be secured. Mr. Bennett had afforded additional proof in the cases cited of the value of the antiseptic method; and as Mr. Stokes had stated the operation could not be undertaken with such favourable prospects, but for the protection thus obtained.

Mr. LAMBERT H. ORMSBY stated that for rickets in the lower extremity he had not adopted the osteotome extensively, but in the case of young children another line of treatment which had been mentioned to him by Mr. Marsh, of St. Bartholomew's Hospital—namely, breaking the child's limb over the knee. That procedure he practised in a couple of cases, doing both limbs at the same time, and in five weeks afterwards the children were running about. He did not assert that there were not cases in which osteotomy should be performed, but he rose to point out that the legs might be broken with the greatest ease in the way he had mentioned in the case of children up to four years of age. After that age

osteotomy might be performed. By holding the limb and his two hands close together he could effect fracture at the very point he wanted, and he never had a compound fracture.

Mr. E. S. O'GRADY said his experience was limited to some half a score of cases; but in none had he had recourse to the elaborate paraphernalia of Lister's dressing. He adopted the old-fashioned dressing with a piece of lint steeped in the blood and friar's balsam. With one exception all the cases healed rapidly, and instead of three or four or five dressings, the primary dressing frequently sufficed, being removed with satisfactory result at the end of three weeks. The Society being a school for educating surgeons, the more they facilitated operations so that men could practise the operations for themselves the better. It might be that the cases he had had were peculiar; but he found intense difficulty in breaking the limb, even after cutting it. In most cases in which he operated he had to deal with the fibula also. The difficulty of breaking the tibia was very great. He had not had very young children to operate on; but he had at different times, as Mr. Ormsby had described, tried to break the bone with his hands, and did not succeed, while he knew of others who had done so. How it was done he could not say. He should protest most earnestly against its being laid down as a doctrine necessary to the successful practice of osteotomy that recourse must be had to Lister's dressings.

Dr. HENRY KENNEDY in reference to the fact that some children of a family were rickety and others not, said there appeared to be a law constantly bearing on the matter, inasmuch as when a bitch had a litter of puppies they were invariably different one from the other, and one being usually smaller than the rest. So in the human family there were instances of one being rickety and the others healthy. M. Trousseau, in his masterly essay on rickets, demonstrated that they were produced artificially in animals.

Mr. W. T. STOKES agreed so fully with what Mr. O'Grady said about the Society being a school for the teaching of practitioners, he would be sorry to let what he had said in reference to Listerism go unchallenged. Whether osteotomy could be performed with equal advantage with or without antiseptics everyone who had seen a compound fracture was as good a judge as the man who had performed osteotomy. He would like to know how many cases of compound fracture recovered without suppuration—not that there was always suppuration in the old days—he did not mean to say anything of the sort; but he did say that in former days compound fractures were, in the majority of cases, followed by free suppuration; while now they were not followed by it.

Mr. E. S. O'GRADY as a matter of order considered he was entitled to state that a great many compound fractures united without suppuration under the plan of dressing he had specified, while he had seen cases in which the Listerian system had been carried out with all the precautions usually adopted, followed by suppuration.

Mr. H. G. CROLY said he had within the last few days performed osteotomy on one leg in the case of a child with very bad rickets. The other leg he intended to operate on in a few days hence. Though he had assisted in many operations for rickets he was not aware of the great difficulty of dividing the bone and the enormous amount of force required with a mallet even in the case of a child four or five years old. To the antiseptic part of the treatment he did not think it necessary to allude as being entirely a matter of opinion with the operator; but he would not dream of operating himself without that precaution.

Mr. W. WHEELER mentioned relative to the elbow-joint cases Mr. Bennett brought forward, that he had himself two cases, one of which was similar to his. He did not operate with a chisel, but having made an incision on each point at the condyles, he passed the saw in and severed the bone. That was an operation he saw recorded in Butcher's work on surgery. Mr. Adams, to whom he showed the case, stated he frequently performed the operation with the key-hole saw, making only one opening instead of two. The point was not to wound the ulnar nerve. However, the patient was now free in his joint, able to extend it and flex it very well. The case was treated antiseptically, but not according to Lister. He presumed it was admissible to observe that, according to Mr. MacCormac Jonathan Hutchinson had stated that Listerism was not at all applicable to compound fractures.

Mr. BENNETT, in reply, expressed himself satisfied with the course the discussion had taken. It had been almost without exception in his favour; there was a point of interest in refer-

ance to Dr. Barton's observations that he thought it well to dwell on for a moment. Dr. Barton spoke of having used simply a carpenter's chisel, hardened by special tempering. Of course, in a child such an instrument might be used; but with Macewen's experience it was prudent to avoid instruments prepared in that way, because he had recorded that some London surgeon had left the greater part of his osteotome in the centre of the thigh of a patient, and he was unable to extract it. Again, where it was necessary to cut through a mass of great thickness it was essential the incision should go straight and be done with a sharp instrument. To remove a wedge the chisel was, as Macewen pointed out, the proper instrument to use, having a sloped or bevelled edge. The arterial hæmorrhage he could quite understand. An accident might occur through the chisel striking some of the vessels by deviating outside the bone itself. With reference to the elbow case Dr. Barton had doubted the correctness of his opinion, but he did so because he had not caught the history of the case, which was that the fracture occurred when the child was two years old, and it was eleven when it came under treatment. Many deformities he had seen straighten, in time and he had almost determined to allow the deformity he had mentioned to remain for the process of growth to straighten it but for the necessity of elongating the limb to be of the same length as its fellow. When the tibia was broken it was impossible to straighten the limb until the fibula was broken which it was with a distinctly audible crash. It would not have been possible to straighten the limb by any means short of fracture of both bones, the absolute certainty of breaking the bone where wanted by using the osteotome, and, in spite of all Mr. O'Grady's observations, the complete immunity from risk in adopting antiseptic treatment made the operation more desirable than even Mr. Ormsby's method of practice. He was glad to see Mr. O'Grady had become an advocate for antiseptic surgery in spite of his own statement; for he closed his wound as rapidly as he could with compound tincture of benzoin, a powerful antiseptic. For his part he always practised antiseptic surgery. As to the occurrence of rickets in children he referred to the case of the middle child of a family of five being so affected, while those born after, as well as those before, were perfectly free. As rickets were not endemic, they did not see all the members of a family, or at all events the subsequent ones, rickety. Mr. O'Grady had confined his observations entirely to the trivial operations; but he did not know had that gentleman undertaken a section of a femur below the trochanters without antiseptic precaution.

The Society then adjourned.

THE Earl Cadogan has been elected to the Presidency of the Chelsea Hospital for Women, which office had become vacant by the death of the Earl of St. Germans.

THE rates of mortality last week in the principal large towns of the United Kingdom per 1,000 of the population were—Brighton 14, Leicester 15, Norwich 18, Hull 19, Bristol 19, Plymouth 20, Birmingham 20, Edinburgh 20, Newcastle-on-Tyne 20, Salford 21, Bradford 22, Oldham 22, Glasgow 22, London 23, Leeds 23, Nottingham 23, Sunderland 24, Manchester 24, Sheffield 24, Wolverhampton 25, Liverpool 27, Portsmouth 28, and Dublin 29.

The rates of mortality in the principal foreign cities, according to the most recent weekly returns, were:—Calcutta 34, Bombay 29, Madras 51; Paris 32; Geneva 21; Brussels 26; Amsterdam 23, Rotterdam 26; The Hague 20; Copenhagen 25, Stockholm 30, Christiania 18; St. Petersburg 63; Berlin 24, Hamburg 23, Dresden 30, Breslau 33, Munich 35; Vienna 32; Buda-Pesth 40; Rome 30; Turin 23, Venice 25; Alexandria 39 per 1,000 of the population.

"SALUS POPULI SUPREMA LEX.

WEDNESDAY, APRIL 27, 1881.

**A NEEDED INSTITUTION.**

WE have at present a number of institutions in this country devoted to the care and treatment of the insane population that deserve, as they constantly receive, the admiration of all who comprehend the good that is achieved in them. Some there are, as there always will be, who will not admit the benefits conferred by our asylums; and possibly, even if these detractors were permitted to arrange the disposition of the mentally unsound in accordance with their own wishes, they would speedily discover in the new scheme subjects for continual complaint. They are not likely, however, to have much opportunity of indulging their passion for change, and we shall probably long continue to merit the encomiums passed on our private asylums by Dr. Beard who recently paid visits of inspection to several of them, and who is loud in praise of their superiority. It is difficult, perhaps, to imagine how it would be possible to do now without the refuges for the insane with which we are fortunately so well provided. That the number of the mentally afflicted would be found to seriously embarrass the relations of social life is evident, and in a certain sense it may be said that such embarrassment is even now produced by the presence among the healthy

population of many persons, especially children, whom it were better for them and their neighbours to have in safer keeping. The truth of this will be revealed to any one who will trouble to attend the reception of the physician held in the out-patient department of any hospital such as the National Hospital for the Paralysed and Epileptic. Here, any day, may be seen numbers of children, and young adults, for whom the care and attention ensured in special retreats is necessary for their comfortable existence, and who yet are not in a condition to necessitate consignment to special hospitals for the insane. Neither are they exactly fit to be classed with idiots, for whom voluntarily maintained and other institutions are provided. They constitute, in fact, a group of patients for whom no adequate provision has been made, or, so far, attempted, perhaps because hitherto their claims to consideration have not been sufficiently pressed. Naturally the chief difficulty to be encountered in any attempt to found an institution of the kind suggested, will be the important one of expense. The cost must needs be considerable, for to be successful the scheme must be completely carried out in every detail; but there is strong reason for supposing that it might eventually prove a fairly remunerative undertaking. There is need, however, to guard at the very onset, against the temptation that could not fail to arise to make the money question paramount: it cannot be done with advantage to the patients it is intended to benefit, and the experience of the past strongly points to such possible weaknesses as it might give rise to. Especially, too, is it desirable that from the outset attempts should be made to bring the ordinary expenses of management within the smallest limit compatible with efficiency, as thereby the charge per head for inmates would be able to be put at the lowest possible amount, an essential consideration, since the vast majority of applicants for admission will come from the ranks of those unable to pay extravagant sums for the maintenance of afflicted relatives, and the greater number of whom will only with difficulty be enabled to scrape together the most modest annual payment. That they would, nevertheless, willingly sacrifice a good deal to secure the benefits of a properly appointed and properly supervised home for their unfortunate offspring their frequent inquiries after such institutions indicates; and it is only in consequence of the frequency with which the want has been expressed that we have been led to advocate the scheme herein sketched out. The average condition of those who would become inmates of these places is that of the lower middle class, from whom chiefly the applicants at special hospitals are drawn. Among them are numbers of course who would find it impossible to contribute anything at all, or but the merest trifle, towards the expense of maintaining their children away from home; but also the number is by no means inconsiderable, who, with more or less difficulty could afford to pay from £12 to £30 per annum for the same purpose. The cost per head of keeping children in an establishment specially set apart for them may be estimated at £25, this, of course, including everything that would be especially needed for the safe preservation of those afflicted with the non-mental nervous disorders. It is possible that the amount will undergo more or

less reduction according to the facility with which the children can be taught to employ themselves in paying labour. As a source of income, however, this can never be expected to be very considerable, although it ought in fairness to find some place in the general estimate of expenses. By making special arrangements, too, for the reception of a small number of so-called "high-class" patients, on whose account higher rates would be paid in consideration of separate lodging and superintendance, an additional income might be obtained, but it is not these who appeal at present for a home. They can always command in some way the treatment necessary for them, while, besides the out-patient physicians' services at some special hospital, the poorer sufferers are entirely cut off from assistance of any kind. It must be borne in mind, too, that these patients are not, like lunatics, permanently in a condition needing instant attention. Possibly their misfortune is equally heavy however, since, at any moment, they may succumb to the influence of the malady that holds them in its bonds. Hence the sore need that they be so placed that they shall always be under the eye of experienced caretakers, to whom their condition will always be clear, and who shall always be at hand to minister to them in extremity; and hence, too, more particularly, the unsuitableness to them of ordinary home-surroundings, amid which they cannot hope for the relief obtainable in an institution regularly appointed to receive them. Asylums for the insane are no place for them either, however excellently conducted. In no sense are they mentally incapacitated, and in the intervals of attacks their association with insane persons would be an outrage on humanity, while at any other time they could not be put with them. Similarly with idiot asylums; they are in no sense idiots, nor fitted to live with idiots, and there is consequently no existing class of institutions capable of receiving them. The fact of such places being wanted is proved again and again each week, and we ourselves have frequently been applied to for information concerning them by parents of children needing the advantages they would confer. We have said they should be built in no mercantile spirit, but in view of the urgent need there is of them, otherwise it were almost better that they should not be founded at all. A few philanthropic medical men would best fulfil the design, and when they had demonstrated the success of the movement, its adoption on a wide scale would follow.

#### STIMULANTS IN WORKHOUSES, AND IN OUT-DOOR RELIEF.

THERE is scarcely any of the taxes which our present social government renders necessary so much complained of as the ever-increasing burthen of the poor-rates; and this complaint arises not only from their actual pressure, but from the rather general idea that they are not all disbursed towards the real necessities of the poor, but frequently for unnecessary, or even injurious, purposes. In few respects is this point now more strongly urged than in regard to the use of stimulants, not only for the treatment of the sick in the union hospitals, but for paupers not in hospital, or even for the recipients of out-door relief. It is not our intention to discuss here the use of

stimulants in the treatment of disease, which is, in our opinion, a question best left to the medical officers of the several hospitals; we will merely observe that, in our experience, there are certain types of disease for the treatment of which alcohol, in carefully-regulated quantities, is essential, and which, in fact, cannot be effectually combated without that remedial agent. In these cases, however, we very much doubt whether the ordinary conventional doses of whisky, brandy, port-wine, &c., &c., are the most accurate way of exhibiting it, for these fluids present quantities of alcohol of ever-varying strengths, flavoured by the essential oils, and, besides, are apt, by constant use, to create in patients an appetite for stimulants which may lead to their ultimate moral and physical ruin. We have for a long time past acted frequently on the advice of Dr. B. W. Richardson, and prescribed definite doses of the proof spirit of the Pharmacopœia (sp. gr. 920) suitably flavoured, and found it, if not quite so agreeable to the palate, accurate in its effects, and, taken distinctly as a medicine, just like the bark, ammonia, or quinine which were used in the same case. We find occasionally instances of gastric irritation where the sedative action of old brandy, or of champagne, are desirable, and where the spirit of wine does not answer; but we repeat that this whole question, where the actual treatment of the sick is concerned, is a matter not for the decision of Local Government Boards, or even of Poor-law guardians, but for the conscience of the medical profession, and as such we bring it under the notice of our readers, merely remarking that indirect harm has often been done by the presenting of ordinary stimulants, and that it is the duty of the physician to minimise this risk.

We would, however, principally call attention to the use, or rather the abuse of stimulants in the case of workhouse inmates not in hospital; and still more of persons in their own homes, in the receipt of out-door relief, and against this system we emphatically raise our voice. Taking the detailed statistics of the unions of the three kingdoms, we find that there is no sort of uniformity either in the amount of stimulants employed, or in their effects upon the death-rates of the inmates. These statistics have been carefully collated and compared by Dr. Norman Kerr, in a very interesting and luminous report, which shows that in some workhouses the quantities of alcohol employed per head are simply scandalous, and considerably in excess of those used by many of the ratepayers supporting them, while in other similar establishments the amount is infinitesimal, being evidently exhibited only in cases of illness or emergency. Further, this report discloses the startling fact that whatever may be the factors of the higher or lower death-rates of these establishments, the use or non-use of alcohol is not one of them, for some of these Poor-law shrines of Bacchus display most favourably, and others equally disastrous death-rates; while the non-alcoholic institutions appear to be similarly situated.

As the health of the ordinary pauper is evidently not affected by the use or non-use of alcohol, the question becomes simply one of discipline and of propriety; and, in these important points of view, we consider alcohol highly objectionable. The public have little idea how it is abused in some workhouses where a great deal of

nursing, sweeping, and other domestic labour is done by able-bodied male or female paupers. In some of these places it is usual to reward such labours by allowances of whisky or porter, which are sometimes consumed by the recipient, and sometimes sold; and, as a result, discipline is gravely interfered with, and police, or even magisterial interference, becomes necessary. The hardest political economist will not deny that the workhouse inmate should receive a diet which will keep his body healthy and well-nourished; but why give him alcohol? Likewise, the aged and infirm, may reasonably look for eggs, beef-tea, and a few such comforts; but for them also, unless in actual acute illness, alcohol is unnecessary.

The distribution of strong drink among the recipients of out-door relief is simply monstrous, and is open to the greatest abuses. Not long ago in this city, an active guardian visited a pauper shortly after the relieving officer had distributed the weekly allowance of food and stimulants. He found the pauper standing on the stairs comparatively drunk, and with the nearly consumed whisky bottle in hand. For strategic reasons the guardian retired; and the pauper was, for the rest of the week, as far as the union was concerned, in a state of compulsory sobriety.

We have spoken at some length upon a growing evil, which appears to us to be a very serious one. Love of drink is, in our humbler classes, our great national besetting sin, and we earnestly appeal to the medical profession in charge of hospitals and workhouses to combat a system objectionable on account of its waste and extravagance; but still more by reason of the social and moral degradation to which it is slowly, but surely, leading.

#### CONSULTATIONS WITH HOMŒOPATHS.

WE are fully agreed in the statement of the *Dublin Mail* that—

“A great deal of nonsense has been written within the last day or two relative to the doctors who attended and the doctors who refused to attend Lord Beaconsfield. The refusal of Sir W. Jenner and the difficulties made by Dr. Quain in the matter, are condemned by those critics as being dictated by nothing better than an undue concern for professional etiquette. Allopathists will not meet homœopaths in consultation, these people think, merely because homœopathy is not orthodox, which word again they think merely means respectable. Now,” says the *Mail*, “it seems to us that Sir W. Jenner and Dr. Quain were actuated by precisely the motives which they were equally blamed for disregarding, and that if they had concurred that one of their body should attend the patient while yet that patient was being treated on homœopathic principles, they would have been guilty of a fraud and shown an utter disregard to the life of the illustrious patient. The two methods of medical treatment, the allopathic and the homœopathic are radically opposed in *rationalité*. Compromise between them is impossible. There can be no compromise between persons who start from radically opposite assumptions and have no fundamental principles in common. It may be that homœopathy would cure Lord Beaconsfield; and it may be allopathy. But a *tertium quid* that partook of the characters of both would mean—if it meant anything—that the patient was to receive no treatment at all. Compromise being impossible, what is the use of consultation? It would only be a waste of time and a degrading false pretence. The result of Her Majesty's intervention was that Dr. Kidd renounced his homœopathic treatment of Lord Beaconsfield, or rather explained

that he had not applied it. He has not used infinitesimal doses. He makes no mention of *similia similibus curantur*, and therefore has totally dropped this cardinal principle of Hahnemann's treatment."

This statement by the *Mail* is the solitary sensible pronouncement of the daily papers on this subject which we have seen. One and all the non-medical newspapers have fallen into the error of representing the variance between homœopaths and scientific physicians as simply a question of etiquette, as if the difference between Hahnemannism and medicine were only a trifling matter of doctrine, with which the outside public can have no sympathy. There never was a representation more unjust to the medical profession or more favourable to the homœopaths.

The dispute is not upon any matter of etiquette or doctrine, but upon the broad ground of professional honesty, and the reasons why a physician refuses to meet an homœopath are easily understood from this point of view. If the *soi-disant* homœopath is a genuine homœopath the physician cannot consult with him because, as the *Mail* says, to do so would be to be guilty of a fraud, compromise between the two systems of treatment being absolutely impossible. If, on the other hand, the *soi-disant* homœopath be only a colourable homœopath—one who acquires business by pretending to infinitesimalism and by practising it as long as the patient is not sick, but who quietly throws Hahnemann overboard when the case comes to require therapeutic treatment—then consultation of an honourable physician with such a person is equally impossible on purely moral grounds. We cannot tolerate the proposition that a physician is justified in meeting an homœopath who has become an allopath for the nonce and to suit the views of that particular patient and consultant, because, in our view, a practitioner who can thus act is not a desirable associate in any sense—moral, social, or professional.

## Notes on Current Topics.

### Death from Carbolic Acid Poisoning.

A CASE of death from the effects produced by carbolic acid, used for hyper-distension of an abscess, is reported by Dr. E. H. Bradford, in the *Boston Medical and Surgical Journal*. The patient was a boy five years old, in whose thigh a cold abscess had formed. An incision was made into it, and the pus being evacuated, it was filled to hyper-distension with carbolic solution 1 in 40. The fluid was well pressed out, and the wound dressed. During the night obstinate vomiting came on, which persisted some hours. The next night it returned, and in the morning the boy was very feeble, his urine being tar-coloured. The carbolic dressing was then removed, and a cloth wet with chlorinated soda substituted. In spite of this precaution, however, death ensued two days later, with symptoms of collapse. Thorax and abdomen alone were examined post-mortem; extensive diffused hæmorrhage was found in the left lung, and both sides of the heart contained dark clotted blood. Spleen was unaltered; kidneys enlarged, firm, and pale, with fatty degeneration of the epithelium

of convoluted and straight tubes. The liver cells contained large and small fat drops. Dr. Bradford concludes that the lesions of greatest consequence were obviously those of the heart and kidneys. It is not unlikely that the extreme quantity of fat found in the liver owed its origin to the causes producing the fatty degeneration of the heart and kidneys. The appearances of all these organs were strikingly analogous to those met with in cases of poisoning from phosphorus or arsenic. The clinical history of the case directly suggests that the lesions found may be attributed to the toxic action of carbolic acid.

### Curious Wanderings of a Needle.

THE curious persistence with which needles have been known to remain in the body for lengthened periods of time is familiar to every surgeon, but a case recently reported in an American daily surpasses all those hitherto detailed. According to this account, a woman stepped on a needle nine years ago, and every attempt to remove it by surgical means failed. For years the patient suffered at intervals from attacks of pain, but notwithstanding, she married about five years ago, and has borne three children. In each pregnancy the pains produced by the needle were felt, but towards the term of the last one they altogether disappeared, and have not returned since. Shortly after, however, the child became querulous and ill, until the mother one day while washing it found the needle, black and corroded, projecting from its thigh. No doubt is felt that this was the veritable needle, but, as we have said, the story is American and, at present, has appeared only in a lay journal.

### An Aesthetic Hospital Ward.

ONE of the wards in the Louth County Infirmary at Dundalk has just been re-opened, having been refitted at considerable expense by Lord Clermont. The ward, which has been named after the noble Lord, in recognition of his generosity on previous occasions to the institution, is 37 feet long by 18. The ceiling is vaulted, having an opening in the centre to carry off the foul air. The walls are formed by a deep brown skirting tile, surmounted by turquoise blue hexagonal tiles, and a moulded cutting tile of brown and lemon colour. The entire forms a dado 5 feet 1 inch in height, reaching to the window sills. The plastering above is finished in Keen's Parian cement, of a delicate salmon colour. An extremely handsome stone chimney piece, 5 feet 8 inches in height, elaborately carved in the upper cross piece, and having the words "I was sick and ye visited me" carved across the front, stands at the end of the ward. The fender is also Portland stone, the fireplace being tiled, and containing a handsome dog grate. Two separate flues open into the wall, bringing down a plentiful supply of fresh air, the upper panes in all the windows being perforated also. A polished pitch pine floor completes the ward, which, for comfort and ventilation, cannot be surpassed. The infirmary is furnished with Messrs. Rowcliffe's patent spiral spring beds, the same as supplied to the New Hospital at Edinburgh. The entire alterations were carried out by Messrs. Sibthorpe and Son, of Dublin, and reflect the highest credit on their firm.

### Royal College of Surgeons in Ireland.

THE annual election of three Courts of Examiners, in medicine and surgery, in midwifery, and in general education for the service of the Irish College of Surgeons for the next year will take place on the 3rd of May. The whole of the present examiners will, we understand, present themselves for re-election, and Mr. Lambert Ormsby, Surgeon to the Meath Hospital, has also announced his intention of seeking election. The new scheme of education and examination upon which the Council has been engaged—in committee—for several months, has at length been matured and reported to the Council at its last meeting. Its final consideration, with a view to its adoption as collegiate law, will take place at the next special meeting of the Council, and we hope then to be able to congratulate the College upon its achievement of the most important reform of medical education in Ireland which has been effected for the last thirty years. We are not yet in a position to publish the scheme, but we are able to state that its sole object is to make the teaching of the student genuine and practical, to afford the pupil every facility for getting through his career of study and examination with greater facility, less expense and more benefit than he now receives, and to make him at the end a more valuable practitioner for the service of the public than he now may be. If the proposed reforms serve these objects, it cannot fail to raise the prestige of the College, and confirm its popularity with Irish students.

### The Provident Dispensary System.

A CORRESPONDENT of one of our contemporaries describes the provident dispensary system in Manchester as follows :

A doctor is engaged by the committee. He takes a private house in a district remote from the dispensary, so that his future private practice may not be injured. Handbills publishing his name and *private* address are circulated in the neighbourhood, and by means of a collector the private patients of the other doctors are canvassed, and pressed to become members. As a matter of fact I can point out numerous instances of shopkeepers who are being attended at the provident dispensary.

It is not news to our readers that in many instances the "committee" are the relatives, tools, and nominees of the doctor, and that that the whole affair is a canvassing trick, to the benefits (?) of which all who are verdant enough to come in are willingly admitted, be they rich or poor.

### Instantaneous Preparation of Mercurial Ointment.

IN the *Archivio di Farmacia*, the following process for the immediate preparation of mercurial ointment is suggested. A decigramme of the purest maltine is diligently triturated with .50 grammes of lard, at a temperature of 20 deg. to 25 deg. C. When thoroughly mixed add 50 grammes of metallic mercury; this will be extinguished by a few moments' rubbing, and lard by other fatty vehicle may be added to make 200 grammes of ointment. So rapid is the process that it looks almost like enchantment. The price of pure maltine is high, but the very small quantity required (which, perhaps, might be reduced) meets this objection to the process.

### The Lay Press on Homœopathy.

A CORRESPONDENT sends us an article from the *Fermanagh Reporter*, devoted to the usual false representation that the differences between homœopathy and scientific medicine are only a matter of etiquette and trades-unionism. It is not worth our while to repeat for the benefit of the *Fermanagh Reporter* the instruction which it has been necessary to administer to other lay journals as to what is the variance between homœopathy and scientific medicine which makes their association impossible and professionally immoral. If it be not of interest to bucolic editors to get up the smattering of knowledge which would make them independent of teaching on these points by medical periodicals, we suggest that they confine themselves to their natural employment of "chronicling small beer."

### The Plague.

THIS scourge has been ravaging the banks of the Lower Euphrates and the villages of Mesopotamia. Quarantine against it has been declared by the Egyptian authorities. In spite of this it is said already to have crossed the Mediterranean, and one or more deaths from it have been reported at Seville, Spain. The littoral cities of Southern Europe are by no means in such superior sanitary condition that all danger is averted of another experience such as Marseilles had in 1722.

### The New French Scientific Journal.

THE Minister of Public Instruction has determined to publish a new scientific journal under the title of *Revue des Sciences*. It is to be printed at the National Printing Office and sold as cheaply as possible. A number containing about one hundred pages will appear every month. Prof. Milne-Edwards is to be the editor of the review, the object of which will be to give an analysis of all the scientific work done in France during the current year.

### Health of Ireland.

THE mortality in twenty large English towns, including London (in which the rate was 23·0) was equal to an average annual death-rate of 22·9; in Glasgow the rate was 22·4, and in Edinburgh 20·0. The average annual death-rate for the week ending Saturday, April 16, in the sixteen principal Town Districts of Ireland was 28·7, the rates were :—Queenstown 5·0, Wexford 8·6, Sligo 9·7, Kilkenny 12·3, Dundalk 13·8, Galway 23·3, Newry 23·3, Lurgan 24·4, Londonderry 24·7, Clonmel 25·7, Dublin 28·1, Belfast 31·9, Cork 32·4, Limerick 37·0, Waterford 37·9, Drogheda 42·3. The deaths from the seven principal zymotic diseases in the 16 districts were equal to an annual rate of 2·0. In the Dublin District, the deaths represent an annual mortality of 28·9. No new case of small-pox has been admitted into any of the Dublin hospitals during the last three weeks, and no cases of the disease remained under treatment, the only patient in hospital on the previous Saturday having been discharged in the course of the week. The deaths (6) from typhus registered during last week are 2 in excess of the average for the preceding five weeks, and also 2 over the number for the week ending 9th instant. Thirty-six new cases of the disease were admitted into the principal hospitals during the

week, being 6 over the admissions for the preceding week; 35 typhus patients were discharged during the week; 6 died; and 93 remained under treatment on Saturday last, being 5 under the number in hospital at the close of the previous week. Six new cases of typhoid fever, and scarlatina were admitted to hospital during the week.

#### Cinchona Bark.

ON April 8, in the House of Commons Captain Price asked the Secretary of State for India whether it was the fact that the Indian Government were exporting large quantities of cinchona bark for sale in London; and whether, in introducing the cinchona plant into India, the Government did so with the object of encouraging private enterprise or of competing in the market with private trade.

The Marquis of Hartington said, that the object of the Government in introducing the cinchona plant into India was to provide an abundant supply of a cheap febrifuge for that country. Almost all the bark produced in the Bengal plantations is manufactured in India for use there; difficulty has been found in treating the produce of Madras plantations in the same way, and hence most of it has been sent to England. It is believed that the sale of this bark has established the reputation of Indian-grown bark to the advantage of private growers; but an experiment is now being made on a large scale with the view to the manufacture of this bark in England on Government account, and if this proves successful it is likely that sales will be discontinued.

#### Albumen in Urine.

BODECKER (*Arch. Pharm.*) has proposed the following test for albumen in urine. The urine is to be treated with slight excess of acetic acid, and then with a few drops of a solution of ferrocyanide of potassium. The mixture is then to be warmed. If albumen be present, even in the smallest quantities, a turbidity is at once produced. On standing for a short time flocculent precipitate appears.

#### Enforcement of Vaccination in Ireland.

THE Local Government Board for Ireland has recently addressed to the Limerick Guardians a timely letter on this subject. The board points out that the sequence of duties necessary to be performed by the various officers in order that defaulters may be punished are commonly discharged so loosely that the law is, in fact, seldom enforced. This is quite true, and the Irish Local Government Board has done well in remonstrating with the Limerick Guardians. But why stop there? Does not the board know that *mutato nomine* the same story might be told of almost every union in Ireland in a greater or less degree.

The defaulters' lists made out by ardent medical officers are habitually ignored by most of the boards of guardians, or the proceedings to enforce the law die of inanition in their passage through many official hands before they can come to maturity.

We observe with satisfaction that the Local Government Board is fully aware of the noxious effects of this method of doing business, and we trust that the board will follow

up its remonstrance with such action as will make people and officers feel that law and regulation must be obeyed.

#### Poor-Law Medical Pensions in Ireland.

ON Monday week last a deputation from the Executive Committee of the Irish Medical Association waited on the Chief Secretary for Ireland at Dublin Castle, by appointment, for the purpose of submitting to him the principles of a proposed Bill to amend the Medical Superannuation Law of Ireland. The deputation consisted of Dr. Chapman, the President of the Association, Dr. J. W. Moore, Chairman of Council, Dr. Speedy, Hon. Sec., and Dr. Jacob, and it was introduced by Mr. Meldon, M.P. The conference was a private one, and the details of the proposed Bill were fully discussed, facts in support of the necessity for a change of law being submitted to the Chief Secretary, who informed the deputation that, while he felt that a strong case had been made for the reforms which they proposed, he could not commit the Government to approval of a Bill until he had conferred with the heads of departments interested in the matter. He suggested that a Bill should be prepared and introduced by a private member, and he promised the favourable consideration of Government for its provisions.

#### The Empress of Germany's Diphtheria Prize.

THE adjudicators appointed to examine the essays in competition for the prize offered by the Empress of Germany to the author of the best work on Diphtheria, have delivered the result of their labours. Nine essays were sent in, not one was deemed worthy the prize. With the concurrence of Her Imperial Majesty, the prize is again offered for competition, the subject being "The Determination of the Causes of Diphtheria, and the Practical Results to be derived therefrom." The last day for sending in essays will be March 31st, 1882, and the decision of the adjudicators will be made known on September 30th. The prize is of the value of 2,000 marks (£100). Essays may be written in German, French, or English, and are to be sent to Professor von Langenbeck, Berlin.

#### Conjunctivitis in the Street.

THE possibility that serious inflammatory consequences may follow exposure to the flying dust-clouds in the streets of towns is proved by the observations of Dr. E. G. Loring, who communicates an article on the subject to the *New York Medical Record*. This gentleman records several cases in which severe conjunctival inflammation has been set up by the filthy dust of the New York streets, the condition of which he describes as worse than that of any other city in the world. His patients complain of, at first, a slight lachrymation, or smarting sensation, or both; soon artificial light seriously disturbs the organ, giving rise to an intolerable burning, pricking sensation, to escape which even bed is sought at the earliest possible hour. The electric light affords the least annoyance to these patients of any artificial illumination; daylight none at all. Hyperæmia of the conjunctiva is the condition present, and it is also almost intractable. Dr. Loring has found the greatest benefit in these cases from a lotion of nitrate of

silver, five grains to the ounce. We here, in London, especially of late, can sympathise with those who suffer in consequence of filthy streets, and there are not a few people, too, who have experienced the evil familiar to New York pedestrians.

### The Small-pox Epidemic.

THERE can be but little question that what looks very like an epidemic of small-pox is, at present, raging in London. In some quarters of the metropolis the number of cases is very large indeed, and already the applications at the various hospitals are in excess of the accommodation available. At Fulham, for instance, there are over 300 patients under treatment, and on some days during last week more than forty applications for admission were received at this institution. In the Holborn districts of London, the disease is very rife, and it has been decided to build a hospital to meet the necessities of this quarter, at Finchley. As might be anticipated, the localities most infested are those such, as Guilford Street, where close and ill-ventilated stables and cottages block every breath of air from the backs of the more pretentious houses. So long as these hot-beds of sickness are permitted to flourish at every possible corner, there will continue the periodical increased mortality from contagious disease; and the pity of it is that each fresh infliction leaves the authorities as apparently obstinately determined to wait its next return with as great apathy as ever. Sanitary inspection is a mere farce as it is now conducted, and will be so until inspectors are appointed with the ability to inspect, and the courage to carry out the task falling to them. As a rule, these men are simply bullies who flee at the mention of infection, and who, as sanitary inspectors, are little better than useless. Small-pox is a present evil with us, and must be met with bold and effectual measures.

THE annual meeting of the General Medical Council commenced yesterday at 2 o'clock. It has been called thus early in the year, in consequence of expected legislation on the Medical Reform Bill. We shall duly chronicle its proceedings in our next.

DR. MACDOWELL, medical officer of Baltinglass Workhouse, co. Wicklow, has been boycotted because he refuses to grant a certificate stating that a man, who was assaulted and wounded the other day, is out of danger.

(FROM OUR NORTHERN CORRESPONDENT.)

**MEDICAL CHARITIES AND PRIVATE PRACTICE IN GLASGOW.**—Under this heading, our contemporary, the *Lancet*, recently contained a letter, signed "R. W. E." We are not much surprised that this letter evoked no reply, for its arguments are unanswerable; and the game of beggar-my-neighbour is so universally indulged in, that it seems good policy to let sleeping dogs lie. It is painfully patent to all sensible people that gratuitous treatment may be overdone; that it is over-

dous in Glasgow; and equally so that it pauperises the profession, and demoralises the public to a melancholy extent. We would advise "R. W. E.," if he desire experience—as he has an equal right to do with the staff of our hospitals—to associate himself with one or two friends and start a *Provident Dispensary*. His professional aim would thus be accomplished without injury to the profession, and benefit to himself and the poorer section of locality in which he practises. The *Provident Dispensary* system has wrought admirably in England; it has fostered and encouraged thrift and independence among the artisan class, and thus weaned them from the demoralisation of unstinted eleemosynary aid at the large hospitals. A *provident dispensary* has been a success in Edinburgh; and medical instruction is associated with it. A similar institution exists in Dundas Street, Glasgow; in connection with its obstetric department, nurses are taught and poor women are attended at their homes, under the supervision of the obstetric physician. The teaching department it is contemplated further to develop. The dispensary has been quietly doing an immense amount of good, which, we regret to say, is only crippled by the inadequate support which it receives from the public. We cannot doubt that if properly represented, a more generous encouragement of this institution would soon be forthcoming.

**THE ABERDEEN EPIDEMIC.**—We understand that the Board of Supervision, with the concurrence of the Lord Advocate, has appointed Mr. Andrew Rutherford, Advocate, and Dr. Littlejohn, Edinburgh, as commissioners for the purpose of conducting special inquiry, under the Public Health Act, into the cause of the epidemic recently prevailing in Aberdeen, and that the commissioners commenced their investigations on Monday last, the 24th inst. The latest reports regarding the throat affection believed to have been caused by contaminated milk are of the most reassuring nature, and it is extremely probable that in the course of a few days the patients now suffering from its effects will have fully recovered. The prompt stoppage of the milk supply has no doubt restricted the area of the epidemic, and the public have the satisfaction of knowing that the directors of the Oldmill Reformatory are making every effort to discover the source of the contamination. The cattle have been found to be in good health, and in excellent condition; the milk is certified as being quite pure, and the water used is the ordinary town's supply. Last week a post-mortem examination was made on the body of the late Mr. John Watt, Advocate, whose death is attributed to the fever. The examination was made on the order of the Sheriff, with the sanction of the Lord Advocate.

**MEDICAL OFFICER OF HEALTH FOR ABERDEEN.**—As the time approaches for the appointment of Health Officer for the city of Aberdeen interest increases and speculation is rife as to the probable result. Eight candidates have presented themselves, of whom one or two are well known in the sanitary world. From reliable information we understand that the real competition will be between three only of the candidates—viz., Dr. Aubrey Husband, Lecturer on Medical Jurisprudence and Public Health in the University of Edinburgh; Dr. Francis Ogston, jun., Assistant Professor of Jurisprudence in the University of Aberdeen; and Dr. Cornelius Fox, Medical Officer of Health for Ilfracombe, Devon.

**DEATH-RATE OF GLASGOW.**—For the week ending with Saturday, the 16th inst., the death-rate of Glasgow was 22 per 1,000 of the population, compared with 24 per 1,000 for the previous week. The deaths registered for the corresponding week in 1880 were at the rate of 24 per 1,000; and in 1879 and 1878 the returns were 25 and 29 respectively.

**OFFICIAL OFFICIOUSNESS IN GLASGOW.**—Dr. James Downie was charged, in Chambers, on the 19th inst., at Glasgow, before Sheriff Balfour, at the instance of the local authority, with a contravention of the Food and Drugs' Act, by selling a bottle of "chemical food" which did not contain the requisite percentage of ingredients. The bottle was purchased in the forenoon of the 3rd of March last at the drug shop at 4 Abercomby Street by Mr. Robert Inglis, ordinary sanitary inspector, for purposes of analysis, and he paid 2s. for the bottle. It was supplied by a girl, who told Mr. Inglis that if he waited till 6 o'clock he might see Dr. Downie. On being analysed by the public analyst the drug was found to contain .47 of a grain of phosphate of iron, and .38 of a grain of phosphate of lime, whereas it should have contained 2½ grains of phosphate of iron and 1 grain of phosphate of lime. For the defence it was contended that Dr. Downie, who had been in partnership with a medical student, had had nothing to do with the shop for the past 18 months, but only used a room off the shop for the purpose of consulting with patients, although the business was carried on in Dr. Downie's name, and with his consent. The Sheriff found the charge proven, and imposed a fine of £3. Now, there are not a few official proclivities which are difficult of comprehension; but the official passion for persecuting qualified medical practitioners is one of the most incomprehensible of the many afflictions of the official mind. It need hardly be insisted on that the circumstances do not bear the slightest intention on the part of Dr. Downie to benefit pecuniarily by cheating the public. The value of the articles in which the syrup was found to have been defective, is almost *nil*; and the strong probability is that the preparation was bought by Dr. Downie, or the shopkeeper, wholesale. Under the circumstances we cannot help regarding the conviction as most grievous, and one in which Dr. Downie has our sympathy. In this good city of sensitive official protection, numerous quacks drive a flourishing trade, ruin in mind and body thousands of young men, unblushingly assume medical titles, and under the very noses of the authorities distribute their pestiferous bills. Would this gushing zeal of the local authority not be more justly and beneficially employed in restraining the raids of the harpies in question, than in the direction commented on above, which every just person must cordially condemn.

**HEALTH OF EDINBURGH.**—For the week ending with Saturday, the 16th inst., the deaths in Edinburgh amounted to 85, and the death-rate was 20 per 1,000. There was no mortality from fever reported, and that from other infectious diseases was low.

**GLASGOW MEDICO-CHIRURGICAL SOCIETY.**—At a meeting of this Society, held on the 15th inst., Dr. Murdoch Cameron read a paper "On Uterine Displacements." An amusing and unconstructive discussion followed, the sole benefit likely to result from which was the astounding amount of uterine derangement which some members of the profession fail to notice. The uterine ellipsis is a veritable puzzle to not a few of us.

### DEBATED POINTS IN SYPHILITIC PATHOLOGY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—If the views of any physician are muddled upon any question in pathology it seems to me that this physician is Dr. Drysdale in reference to syphilis. The truly wizard-like vagaries of syphilis will not, in our present state of pathological knowledge, permit even a logical, and I might almost say, statistical mind, like that of Dr. Drysdale to grasp with preci-

sion and accuracy its mysterious workings, and could Hunter again appear upon the scene of human pathology, he might truly say—

"What fate ordained may none avoid; needs must a day befall  
Of chances unforeseen, that spite of all  
Man's scheming, part will grant and part deny!"

I am glad to find Dr. Drysdale's hitherto immutable confidence in the experience of French writers seems at last to be undergoing some change, and he now disagrees with the researches of MM. Gosselin and Desprès in reference to syphilitic ulceration of the rectum.

Dr. Drysdale seeks the experience of others upon this question, and I am most happy to furnish him with some information on syphilitic ulceration of the rectum which has been furnished to me in the course of my practice. During the years 1874-75 I had a rather unusual number of cases of syphilis of the rectum in the wards of the Sick Asylum at Highgate in females (not in males) and I published in the "Transactions" of the Pathological Society (vol. 26) the notes of two cases which I think are of interest as they present many features which have an important bearing upon the point raised by Dr. Drysdale, and which are in agreement with his own views, namely, "That ulcers of the rectum, and stricture of that part are due to tertiary syphilis or to secondary eruptions—mucous tubercles—in the neighbourhood." I find upon looking over my cases in the Pathological Society's "Transactions," just referred to, that I made the following observation:

"It has been my experience that, in connection with the history of syphilitic disease of the rectum one does not, as a rule, find chronic periosteal disease with necrosis, caries of bone, but rather a determination to the skin, connective tissue, and mucous membranes. Hæmorrhages from the lungs and albuminuria are associations by no means uncommon. Psoriasis of the tongue and of the palms of the hands and soles of the feet, condylomatoid thickenings around the anus and diffuse cicatrization of the skin from previous ulcerations.

The primary ulcers in these changes are peculiar and typical, and spread very rapidly. They resemble to some extent superficial lupus. *In all my cases there was a clear history of previous syphilisation.* Now, a word or two in reference to treatment. I always found that the administration of mercury (bichloride), with an occasional dose of iodide of potassium was necessary, and as a local application to the sores nothing answered better than calomel paste, but I would urge the early performance of colotomy in all cases where the stricture was persistent and severe.

I am, Sir, your obedient servant,

THOMAS STRETCH DOWSE.

14 Welbeck Street, Cavendish Square, W.C.

April 14, 1881.

### ALLEGED CONCEALMENT OF DISEASE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Under the above heading you publish what purports to be an accurate report of an inquiry by the Local Government Board Inspector into certain charges brought against me as Medical Officer of Health for the Bailieboro' Dispensary District. That report puts the charges in this way:—

No. 1.—"Mrs. Lancashire was charged with bringing a case of typhoid fever into the district."

No. 2.—"Dr. Clarke stood charged with co-operating with Mrs. Lancashire."

With regard to No. 1, I think it only right to state there was no such, nor any, charge. No. 2 more nearly concerns myself, and with regard to it I desire to submit an extract from a letter addressed by the L. G. Board to the Bailieboro' Board of Guardians, and bearing date 2nd April, 1881.

After setting forth the evidence taken at the inquiry, the letter goes on to state, with reference to the examination of Mrs. Lancashire, "Her evidence generally, therefore, corroborated as it is by that of Dr. Clarke, is, in the opinion of the Local Government Board, sufficient to prove that the latter did not, as alleged, co-operate with Mrs. Lancashire in placing her son when suffering from fever in a house occupied at the time by other persons, and Dr. Clarke must, therefore, be held exonerated from culpability in regard to his action in the matter as Medical Officer of Health.

With reference to the *ex parte* statement of the facts admitted to your columns last week I will say nothing; your own judgment will tell you whether such an admission was

justifiable or not, and I may further add concerning the charges preferred against myself, I think the extract given above is quite a sufficient answer.

I am, Sir, yours, &c.,

JOSEPH CLARKE,  
Medical Officer of Health, Bailieboro'  
Dispensary District.

April 15, 1881.

[The notice to which our correspondent refers was taken *verbatim* from the local paper. We have pleasure in publishing Dr. Clarke's letter, and intended to have made equally public the decision of the Local Government Board which the letter records. Dr. Clarke is fully acquitted of the charges made against him.—ED. M. P. & C.]

## Literature.

### AIDS TO DIAGNOSIS. (a)

THE acquisition and cultivation of diagnostic power is of the first importance to the future practitioner; his success will depend primarily on the degree to which he is a diagnostician, and in comparison with this his skill in treatment is unimportant, because, without it, he is a mere empiricist who prescribes without aim, and who relieves by good luck or kills through misapprehension. It is, therefore, eminently desirable that the means whereby students may be enabled to develop into creatures of observation in the highest sense; whereby they may become acutely sensitive to physical and pathological conditions that influence the progress of disease; and further, whereby they may rationalise and deduce aright from the facts they have been trained to note, shall be accessible and sufficient. That these have been present in the past can hardly be said in truth, but that daily increasing attention is being paid in our schools to the imperative duty of educating medical students in the elements of accurate diagnosis, is fortunately clearly evident. In this connection the most recent additions to the "Students Aid" series of manuals acquire particular value, and it is matter for congratulation that two teachers of such proved ability as Drs. Fothergill and Thorowgood, have been induced to write the volumes on diagnosis under review. Dr. Fothergill explains in a short preface that "semeiology" is that by the aid of which an experienced practitioner is enabled to obtain such verbal information from his patient as leads him to neglect the use of his instruments of precision. It is in effect the science of signs that are apparent to the unaided senses. The nature of the work, which is peculiarly original, is explained in this description, and it need only be said that the manner of its execution is worthy of its author's reputation. Dr. Thorowgood's contribution to the subject of diagnosis includes a discussion of the conclusions deducible from information gathered with the aid of "instruments of precision." The stethoscope, laryngoscope, sphygmograph, &c., are briefly noticed, and the symptoms revealed through their employment described. On cardiac diseases Dr. Thorowgood is especially clear and precise, the descriptions of the appearance seen in connection with it being most admirably drawn. We cannot too strongly express approval of these two small volumes. Circumscribed as they are, they contain an amount of information and suggestion invaluable to every student of medicine, and of a kind, too, that has been seriously wanting in the past. The "Aids to Diagnosis" are among the most serviceable students' guides published in recent times.

### RELAPSE OF TYPHOID FEVER, ESPECIALLY WITH REGARD TO TEMPERATURE. (b)

This work was only seen in its finished state by its lamented author shortly before his eyes closed in death. The main object in view is to distinguish the *relapses* which happen

(a) "Aids to Diagnosis." Part I. "Semeiology." By J. Milner Fothergill, M.D. Part II. "Physical Diagnosis." By John C. Thorowgood, M.D., &c. London: Baillière, Tindall, and Cox. 1881.

(b) "Relapse of Typhoid Fever, especially with regard to Temperature." By J. Pearson Irvine, M.B., B.Sc., F.R.C.P. London: J. and A. Churchill. 1880.

in the course of typhoid fever, such as occur in other diseases, especially pneumonia, typhus (on rare occasions), and relapsing fever. This the author illustrated by means of a series of temperature charts, and by the record of cases. He distinguishes between relapses properly so-called, and "recurrences of the original attack with all the phenomena of that attack," and relies in his diagnosis of relapse upon the regularity of the temperature, rather than on the eruption, stools, &c., which may not be typical either in the primary disease, relapse, or recandescence (p. 3).

That difficulties exist in regard to the precise phenomena to which the term *typhoid fever* is applied is a circumstance rendered very clear by remarks interspread throughout the pages of this work. For example: "More than all other acute specific diseases typhoid fever presents itself in unwritten variety (p. 3). Complications may modify typhoid at any stage (p. 4). It has been stated that primary typhoid may run its course without the least fever (p. 7). There yet remains in all directions much uncertainty in regard to the peculiar disease called typhoid fever (p. 13). The fact is that typhoid fever remains a puzzling disease, and the more one studies its intricacies the more conscious must he become of caution at the bedside (p. 37)." From all this, and more that might be quoted, does not this work afford confirmation of the existing urgency that a definite decision should be authoritatively given, as already indicated; that is, as to whether typhoid fever is distinct and specific in its nature, a condition, or series of conditions, occurring in the course of a variety of diseases. In fact, that a distinct reply should be given to the query, *What is it?*

### CLELAND'S DISSECTOR'S GUIDE. (a)

DR. CLELAND'S little manual of dissections, now in its second edition, contains plain and easily followed directions for enabling the student to display in the best manner the parts of the subject he is at work on. The plans suggested are not always in accordance with the common usage, but when trial is made of the altered methods, they will be found of practical value, from the increased facilities they afford for viewing the structures exposed by them. The work makes no pretence at descriptive anatomy, it is, in effect, what it pretends to be, viz., a dissector's guide; and this position it fills most admirably.

### MANUAL OF THE PHYSICAL DIAGNOSIS OF DISEASES OF THE HEART, INCLUDING THE USE OF THE SPHYGMOGRAPH AND CARDIOGRAPH. (b)

It is gratifying to us to welcome the appearance of the third edition of Dr. Sansom's small but comprehensive and practical book on the Physical Diagnosis of Diseases of the Heart. The reader of these remarks scarcely needs reminding of the enormous mass of extant literature on the heart and its diseases, and from this Dr. Sansom has gathered much that is on record and of proved utility, while he has compared the statements of authors with his own extensive clinical observation and experience. Lecture III. on palpation and the pulse is worth careful study. That a rigid, unyielding pulse indicates atheroma of the blood-vessel is doubtless true, and probably when the atheromatous change has extended so far as the radial artery the patient will be past the prime of life, but we have seen a very atheromatous condition of the aorta in a man very little over forty, and in those who had lived in towns, and had taken wine and spirits freely, the atheromatous change in the vessels may be found even at an earlier stage than that named. Slowness of pulse as a sign of atheroma of the aorta is attributed probably to mechanical irritation of the branches of the vagus nerve. The observations (p. 21) on pericardial friction are good and well worthy of perusal. We believe their correctness will stand the test of bedside practice well.

(a) "A Directory for the Dissection of the Human Body." By John Cleland, M.D., F.R.S. Second Edition. Smith, Elder, and Co. 1881.

(b) "Manual of the Physical Diagnosis of Diseases of the Heart, including the use of the Sphygmograph and Cardiograph." By Arthur Ernest Sansom, M.D., F.R.C.P., Assistant-Physician to the London Hospital, Physician to the North-Eastern Hospital for Children, and late Physician to the Royal Hospital for Diseases of the Chest. Third Edition. Pp. 300. London: J. & A. Churchill.

To Part II. we would call especial attention. This part treats of the use of the sphygmograph and cardiograph in the diagnosis of heart diseases. Much information is given in small space, and though we do not ourselves attach much importance clinically to the teachings of either sphygmographs or cardiographs, yet there is no question that these instruments are not without interest and some amount of practical value in both physiological and pathological research. The practical bedside physician will soon judge which part of this useful book is the one to help him to form his opinions and direct his treatment in a case of heart disease.

### CRAWFORD v. THE BRITISH MEDICAL ASSOCIATION.

THE following is an abstract of the medical evidence for the defence given by Dr. F. B. Quinlan, Professor of Materia Medica in the Catholic University, in the recent trial at Cork, to which we referred in our issue for April 13th:—

Dr. Quinlan said he had been twenty-five years in practice in Dublin. Knew of pilocarpine about four years. Had used it in hospital and with private patients. Was one of the first physicians in this country that investigated the properties of pilocarpine. Witness then explained the properties of pilocarpine. He first tried it on himself, as he always did with new medicines. He had formed a very favourable opinion of it. It was a most exact and uniform medicine in its action when injected hypodermically.—To a juror: There is no difficulty about variation in the action of pilocarpine; it is much more uniform in its action than Epsom salts. Two grains of nitrate of pilocarpine in sixty minims of laurel water was the solution which he generally employed; his usual dose was from one-fourth to one-third of a grain. Pilocarpine acted in about five minutes, throwing the patient into a profuse perspiration. Hypodermic injection was becoming every day a more favourite method of medication. Morphia was much more dangerous as an injection than pilocarpine was. As to pilocarpine being an active poison, he had most serious doubts about it. It was absurd to describe the injection of pilocarpine as an operation at all. He had used pilocarpine in various diseases: malignant measles, scarlatina, and above all in Bright's disease, in scarlatinal dropsy, and in acute nephritis; it did not act on the kidneys. Its use was become a matter of ordinary routine. He constantly allowed house-surgeons, and even intelligent nurses, to administer morphia, which was much more dangerous than pilocarpine. Having heard the evidence as to the condition of the child, he believed it was moribund when the pilocarpine was administered, and that the system was incapable of absorbing it. He never knew a case of ordinary scarlatina in which the eruptions were delayed for four days; two days were the outside limit according to his experience. Witness concluded by expressing his firm conviction that the child died of malignant scarlatina; and that the pilocarpine had nothing to do with its death.—Cross-examined by Mr. Atkinson, Q.C.: I have read the work of Dr. Tanner; I do not agree with him that the rash is sometimes delayed three or four days; pilocarpine is a very effective and a very safe remedy; I would not say it was wrong to administer a dose of pilocarpine in three hours after the first dose had been given, but I think it would be unnecessary. I do not think wet packing is necessary in such cases, but different doctors have different modes of treatment. I don't know that it is an active poison at all. Professor Fronmüller, of Fürth, says, in last month's number of the *Specialist*, that pilocarpine is at once powerful and innocent. My usual dose is a quarter of a grain, and if I find that does not do, I increase the dose.—Notwithstanding that you did not see the case, you took upon yourself to express an opinion that the child died of suppressed scarlatina? I was obliged to answer the question put to me.—Was it wrong, in this particular case, to direct the operation to be repeated every three hours? I

don't think it was.—You thought it right, you say, to experiment upon yourself when you got pilocarpine first? Yes, but I would like to explain. That was four years ago, and the medicine was a new one. I had no exact information as to what it would do, and tried it upon myself. I did the same with hydrate of chloral. Last year pilocarpine was in every text-book; every student knew all about it, and what it would do; so that Dr. Jones need not have tried it upon himself.—Did you see Dr. Adderley's evidence to the effect that ten minutes after the administration of the drug the condition of the patient changed altogether and vomiting commenced? I saw that; and I may mention that vomiting is a constant accompaniment of the closing scene in malignant scarlatina. There has been an opinion among the profession, and I had it myself, that pilocarpine was an active poison, and it was quite right.—Have you read the evidence that up to this occasion in September, 1880, the most distinguished medical men here have never used this drug? I have, and I am not at all surprised. The state of medicine in various parts of Ireland would astonish you still more.—And you describe injecting this drug hypodermically as an ordinary practice? As my ordinary routine practice. If anyone said that I had made a dangerous experiment by injecting pilocarpine, I would either demand an apology or place the matter in the hands of my solicitor. When people talk about putting men in the dock, and things of that kind, they must not be too thin-skinned. The attack made on Dr. Jones was ignorant, violent, unscrupulous, and malignant.—His lordship said that Dr. Quinlan had given most interesting evidence.—The Foreman said that the jury were unanimously of opinion that further medical evidence in the case was not needed. Mr. Porter, Q.C., said the other medical evidence they had to give was of the same nature as that of Mr. Hart and Dr. Quinlan, and the intimation from the jury would materially shorten the case. Foreman: We are unanimous, my lord. Mr. Porter.—Then I close.

Royal College of Surgeons of England.—The following candidates having passed the necessary examination for the diploma were duly admitted members of the College at a meeting of the Court of Examiners on Tuesday, April 19th:—

Awdry, Walter Robert	Platt, W. Brewster, M.D.
Beyer, H. G., M.D. New York	Pomfret, Henry Waytes, L.S.A.
Black, William Gladholm	Potter, Edward Furness
Cox, James, M.D. Melbourne	Shelwell, O. B., L.R.C.P. Lond.
Eames, William, L.R.C.P. Ed.	Stokes, Leonard
Holberton, H. N., L.R.C.P. Lond.	Thornton, Wilfred Burrell
Howe, J. Ernest, B.A. Cantab.	Trotter, Walter Octavius
Jennings, J., L.S.A.	Walsh, J. H. Tull
Kaesser, Jean, M.D. Bale	Wells, Alfred Ernest
Kelly, Th., M.D. McGill Univ.	West, John Arthur
Oswald, R. J. W., L.R.C.P. Ed.	Wight, Ernest Octavius
Palmer, Eli Talbot, L.S.A.	

The following were admitted members of the College on Wednesday, April 20:—

Brathwaite, R. Welsh, L.S.A.	Makeham, H. W. Payne, L.S.A.
Browne, O. A., M.A. Cantab.	O'borne, H. Rochester, L.S.A.
Cory, William Howard	Pearse, Walter, L.R.C.P. Lond.
Downing, Charles	Row, Frederick Everard
Hallowes, Herbert Chaworth	Shaw, Frank Herbert
Hatton, Edward F., M.D. Toronto	Stephens, Guy Neville
Knowing, Ernest M., B.A. Cantab.	Strutts, Peter Frederick
Luscombe, Thomas B., L.S.A.	White, Percy Harry, M.B. Edin.
Maddison, William Thomas	

University of St. Andrews.—The following gentlemen, having passed the required examinations, had the Degree of Doctor of Medicine conferred upon them on April 21:—

Call, Thomas James, M.R.C.P. Ed., L.F.P.S. Glasg., Ilkley, Yorks.
Chaple, Charles, L.S.A. Lond.
Finucane, Thomas Dawson, L.F.P.S. Glasg., L.M., Black Rock, Dub.
Lycett, John Allan, M.R.C.S. Eng., L.R.C.P. Lond., L.M., W'hampton.
Murray, William Fettes, F. & L.R.C.S. Edin., Forfar.
Oxley, M. G. B., M.R.C.S. Eng., L. & M.K.Q.C.P. Irel., Liverpool.
Spooner, Edward Munro, M.R.C.S. Eng., Blandford.
Tibbitts, H., M. & F.R.C.P. Edin., L.R.C.P. Lond., M.R.C.S. Eng., Lond.
Tily, James, L.R.C.P. Edin., M.R.C.S. Eng., L.M., Richmond.
Trend, T. W., M.R.C.P. Ed., M.R.C.S. Eng., L.R.C.P.I., Southampton.
Mackey, J. S., M.A. Ed., M.B. & C.M., St. And., Huerva, Spain.— <i>In absentia.</i>

At the same time the following gentlemen had the Degree

of Bachelor of Medicine and Master in Surgery conferred upon them, after examination:—

Hanson, John Edward, L.R.C.S. Edin., London. Lowe, George, L.R.C.P. Edin., Darlington. M'Nunn, John Alexander, L.R.C.S. Edin., B. Ifast.

The following passed the first M.B. examination:—  
Bowie, Alexander, Edinburgh. Redpath, Robert Knox Wighton, Edin.

## NOTICES TO CORRESPONDENTS.

**CORRESPONDENTS** requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

J. M. W.—There can be no question as to the desirableness of health officers possessing information of cases within their district, but we are uncertain as to the powers for compelling such returns; we will, however, look up the matter and report in our next.

**ACCIDENT INSURANCE.**—From a return for the last twelve months compiled by the Accident Insurance Company, it would seem that so high a percentage as one person in every twelve insured, claimed and were paid, for injuries received during the year. Of the 1,464 claims, 19 only were for fatal accidents.

**SUPERANNUATION ASSESSMENT.**—Please state in your next issue of the *Medical Press* if, in seeking superannuation, a medical man will be allowed to count his appointment as "consulting sanitary officer." He is aware the sanitary officer does not count, but it is supposed the other does.

[The L. G. B. has decided that no sanitary salary can enter into the computation, inasmuch as the Public Health Act was passed subsequently to the Superannuation Act.—*ET.*]

**MEDICAL OPENINGS IN THE COLONIES.**—What are a medical man's chances of getting on either in Australia or New Zealand? I have nothing to depend on for a living but my profession, and I am not suited for dispensary work especially night-work in the winter time in this country on account of having a delicate chest.

[Some years ago there was a good opening for medical men in Australia and New Zealand, but latterly the supply has been quite equal to the demand, and unless a man has enough to support himself for a year or so, or has a certainty of an appointment, it is hardly advisable to go out *merely on spec.* You might, however, get employed by some of the steamship or shipping companies trading to the colonies, and by taking a few voyages, and seeing the large seaport towns, thus make yourself acquainted as to the best places to settle in, or as to the probable chances of advancement. The South African Colonies are also suitable with regard to climate, and offer, perhaps, as good a chance of getting on.—*ED.*]

**VACCINATION.**—Are private practitioners paid by the Local Government Board for successful cases of vaccination?

[No, only dispensary medical officers. See Vaccination Amend. Act, sec. 6, page 618, "Irish Med. Directory."—*ED.*]

**LOST DIPLOMAS.**—A year ago, when getting a dispensary appointment for first time, I had my diplomas with me and left them at board-room with clerk of union; I called for them afterwards and was told they were all right in desk. Again I called, and found my three diplomas missing (two from King and Queen's College of Physicians, and one from Coombe), and only one to be had (L.R.C.S.I.).

[If the clerk cannot, or will not, produce them, write to the L. G. B. Your appearance in the Medical Register will be sufficient legal proof of your qualification for most purposes, but for some appointments the diplomas themselves are necessary, and also are almost essential for foreign practice.—*ED.*]

### JENA DEGREES.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—I read with astonishment and regret the announcement in your last number of the death of Dr. Hardwicke, Coroner for Central Middlesex. It seems to me to be hardly fair, or in good taste, to speak thus of a public man who has left behind him a somewhat famous name. You say "Mr. Hardwicke, the well-known Coroner for Central Middlesex, and familiar to newspaper readers as Dr. Hardwicke, died," &c., &c., clearly insinuating that that gentleman had passed before the public falsely as a graduate in medicine when he had no right to do so, when, in fact, he was a graduate in medicine, after regular examination, of the University of Jena, and had been so for many years, and always had been known by his brethren as such. I hope, Sir, the paragraph in your paper was thoughtlessly inserted without your knowledge, for were it otherwise, your Journal would not find such high favour as it has hitherto done with

Yours obediently,  
Sheffield, April 20, 1881. "AN OLD READER AND ADMIRER."

[\* Our correspondent's zeal has somewhat outrun his discretion. We fail to see the unfairness or bad taste in speaking of a man under his proper and legal title. It is quite true the deceased coroner, for whom personally we entertained the highest respect, was popularly known as Dr. Hardwicke, but we do not write for the populace, and our correspondent will find, on reference to the official Register or the *Medical Directory*, that this gentleman's only diplomas are M.R.C.S. and L.S.A., therefore, to describe him as Dr. Hardwicke would have

been manifestly incorrect. We were unaware that the deceased possessed a Jena degree; if he had one he sedulously kept it in the background, being probably, not proud of a distinction which could be purchased and flaunted before the public by quacks of the type of the notorious Dr. Smith, of Burton Crescent.—*ED.*]

**CARMICHAEL COLLEGE, DUBLIN.**—At the last meeting of the private teachers attached to the Carmichael College, Dr. Loftus Stoney in the chair, the following resolution was unanimously passed: Resolved—"That we cannot allow Mr. Lambert H. Ormsby, F.R.C.S.I., Surgeon to the Meath Hospital and Co. Dublin Infirmary, to retire from the Carmichael College Grand Term without placing on record our sense of the courtesy, ability, and efficiency with which he at all times discharged his duties as surgical teacher, and which we feel to have largely contributed to the successful undertaking of the Term."

**ERRATA.**—In our abstract of Dr. Guy's paper on "Temperature and its Relation to Mortality," published in our last two numbers, two misprints occur which require correction. At page 311, second paragraph, second column, line 9, read 81; and in the table at the foot of page 312, at the head of the first column under "Difference of Temperature," for noon read *morn.*

### VACANCIES.

Birmingham Children's Hospital.—Resident Medical Officer. Salary, £80. And an Assistant Resident. Salary, £40. Both with board, washing, &c. Applications to the Secretary on or before May 4.  
Hereford General Infirmary. House Surgeon. Salary commencing at £100, with board. Applications to the Secretary before April 30.  
Bathdown Union, Bray and Rathmichael Dispensary.—Medical Officer. Salary, £110, and £27 10s. as Public Officer of Health. Election, May 2 (See Advt.).  
Sherburn Hospital, Durham.—Resident Medical Officer. Salary, £250. Applications to the Rev. the Master, Sherburn House, Durham, before May 20.  
Torbay Hospital and Provident Dispensary, Torquay.—Senior House Surgeon and Provident Medical Officer. Salary, £100, &c. Applications to the Hon. Sec., not later than May 30.

### APPOINTMENTS.

CARTER, R. W. F., L.R.C.P. Ed., L.F.P.S.G., Medical Officer for the Workhouse of the Dulverton Union.  
CHADWICK, W. F., M.R.C.S.E., Medical Officer for the Second District of the Oldham Union.  
DOBBYN, W. A., M.R.C.S.E., Resident Surgeon to the Beechworth Hospital.  
DOYLE, C. W., M.B., C.M., Medical Officer for the Sixth District of the Norwich Union.  
HARRIS, A., M.B., C.M., Medical Officer for the Dalston District of the Carlisle Union.  
KIERNAN, L., M.R.C.S.E., Medical Officer for the Harrow District of the Hendon Union.  
MALONE, M. J., M.D., F.R.C.S.I., Consulting Physician to Barrington's Hospital, Limerick.  
MASON, S. B., L.R.C.P., L.F.P.S.G., Medical Officer and Public Vaccinator to the Pontypool District of the Pontypool Union.  
MURRELL, W. M. D., M.R.C.P.L., M.R.C.S.E., Lecturer on Materia Medica and Therapeutics at the Westminster Hospital.  
O'CONNOR, M. R., M.D., M.Ch., Visiting Physician to Barrington's Hospital, Limerick.  
O'GILVIE, L., M.B., C.M., Lecturer on Zoology and Comparative Anatomy at the Westminster Hospital.  
PRATT, B., M.R.C.S.E., Resident Medical Officer to the Royal United Hospital, Bath.

### Births.

BAINES.—April 19, at Birkdale, Southport, Lanca., the wife of A. H. Baines, L.R.C.P.L., of a daughter.  
BURNBY.—April 21, at the Greenwick Infirmary, the wife of W. C. Skardon Burney, M.D., of a son.

### Marriages.

BALFOUR—USHER.—April 21, at 1 Eton Terrace, Edinburgh, G. W. Balfour, M.D., F.R.C.P.E., to Henrietta, eldest daughter of the late James Usher, Esq.

### Deaths.

CHADWICK.—April 7, at Butterworth Hall, Milnrow, Lancashire, John Chadwick, M.D., L.R.C.S. Ed., aged 66.  
CHARLESLEY.—April 17, at Graham's Town, South Africa, W. P. Charlesley, M.D., late Principal Medical Officer, Ceylon, aged 56.  
DAFF.—April 23, at 21 Queen Anne Street, Cavendish Square, London, Helen, youngest daughter of George Duff, M.D., of Eglis, N.B.  
JARVIS.—April 3, at Lea Side, Harrow, George Harvey Thompson Jarvis, M.R.C.S.E., aged 58.  
KIRKMAN.—April 11, at Courtraud Terrace, Kensington, J. M. Kirkman, M.R.C.S.E., late of Manchester, aged 49.  
KNIGHT.—April 20, at Bournemouth, Eliza, wife of Alexander H. Knight, M.D., of Keswick, Cumberland.  
PHILP.—April 2, at Brighton, Francis Richard Philp, M.D., in his 82nd year.  
SHEWAN.—April 16, at Princes Square, Baywater, Deputy Inspector-General A. Shewan, Indian Medical Service (Retired List).  
STEPHENS.—April 12, at Warwick Villa, Abbotsford Road, Redland, H. Oxley Stephens, M.D., M.R.C.P., aged 75.  
WALLER.—April 14, at Gipsy Hill, S.E., T. Waller, M.R.C.S., Surgeon-Major, Bombay Medical Service (Retired), aged 70.  
WAYLEN.—April 10, at Culver Street, Colchester, Ed. Wayley, for twenty-nine years Surgeon to the Essex Rifles Militia.  
WILLIS.—April 17, at 2 Waverley Terrace, Bray, Dr. Thomas Willis, sen., in the 91st year of his age.

## General Medical Council.

TUESDAY, APRIL 26TH, 1881.—FIRST DAY.

DR. ALFRED HENRY MCCLINTOCK and Mr. James Spence, F.R.C.S., were admitted members of Council, in the room, respectively, of Dr. Hudson and Dr. Andrew Wood, deceased.

### PRESIDENT'S ADDRESS.

The President, Dr. ACLAND, delivered an address of some length, explaining why the Council had been convened, and referring to the work before it. He feelingly spoke of the death of Lord Beaconsfield, and of his funeral being then in progress.

### PHARMACOPEIA COMMITTEE.

Dr. PITMAN, in moving the appointment of a Pharmacopœia Committee, deprecated any intention of issuing a new pharmacopœia, four thousand copies of the old one being still on hand. He urged the appointment as being desirable for reporting annually to the Council.

Sir WM. GULL, seconding the motion, thought the committee ought to prepare an annual addendum. He owed nothing to the official book, but was much indebted to Mr. Squire's volume. A book fourteen years old was useless as a pharmacopœia.

Dr. A. SMITH supported this proposition. Last year seven hundred copies of the pharmacopœia were sold, so that a new edition would be required in three years. He hoped the committee might do something in three months.

Mr. MACNAMARA thought it useless to re-appoint a committee to do nothing, and strongly endorsed Sir W. Gull's suggestion. Revision would be a lengthy and heavy work, and would scarcely be ended till the new edition was needed.

Mr. SIMON suggested that frequent changes in the pharmacopœia would do harm. He thought, however, the Council should supervise the work constantly, and would support the motion. He hoped serious changes would not be often made in the work.

Dr. PITMAN expressed gratification at the way in which the motion was received.

The motion was then carried.

Sir WM. GULL proposed that yearly reports be made to the Council by this Committee, as to addenda to the pharmacopœia.

Dr. PYLE seconded the motion, which was carried.

### PROFESSIONAL EXAMINATIONS IN 1880.

A series of tables showing the results of professional examinations in 1880 were presented from the various examining bodies.

Mr. SIMON wanted to know if it might not be desirable to have tables of "pluck and pass" from preliminary examining bodies.

Mr. TURNER pointed out the impossibility of this, since it was unknown what candidates at these examinations were or were not intended for the study of medicine.

Mr. THALE thought such returns might be had concerning the rejected candidates at final professional examinations.

Dr. STORRAR said that the ultimate intention of the candidates at London University matriculation examination could not be determined.

### ARMY AND NAVY MEDICAL DEPARTMENTS.

Tables of returns were presented from the army and navy medical departments, showing the diplomas, &c., possessed by candidates at the examinations held by these departments, and the thanks of the Council were directed to be tendered for them to the Directors-general of the respective departments.

### PRELIMINARY EXAMINATIONS.

Letters from the Royal College of Surgeons of England, the University of Dublin, and other bodies were read, in which reference to the Council's requirement as to preliminary examination was made. The College of Surgeons desired to intimate that "the giving up of the College preliminary examinations renders it in the highest degree desirable that the General Medical Council should, so far as may be possible, require that examinations recognised in lieu of the College examinations should be held at such times and places as may best suit the convenience

of candidates who desire to enter the medical profession." The University of Dublin approved the course pursued by the English Royal College, and the general tenour of the replies was to the effect that the existing examinations were adequate to all important needs. The Registrar having read reports of the Executive Committee concerning the replies,

Dr. STORRAR indignantly drew attention to the course of the Executive Committee in acting as it had done in reporting on matters which could properly only be discussed in full Council.

Dr. PYLE put forth a question on the same subject.

Mr. MACNAMARA said it was to be regretted the Executive Committee did not bring before the Council the scheme of which a draft had been prepared. He thought every member of the Council ought to be supplied with the programme of examinations, &c. He distinctly objected to the Report of the Executive Committee being read.

On the suggestion of the President, Prof. HUMPHRY read the Report of the Executive Committee on the question of preliminary examinations. He said that following the action of the Council last year, the Royal College of Surgeons resigned their preliminary examination, and the College of Preceptors proposed to hold an examination in place of it, and asked the Council to recognise it as an efficient test of preliminary education. He considered, under these circumstances, that the Executive Committee were compelled to present a Report, of which he moved the Council's acceptance.

Mr. TEALE seconded the motion.

Dr. STORRAR persisted there was no necessity for this action by the Executive Committee. The Committee, since he became a member of the Council, had usurped the functions pertaining to the Council, and he could not consider it right for it to do so.

Dr. PITMAN defended the action of the Committee.

Dr. A. SMITH said the constitution of the Executive Committee had changed since Dr. Storrar was a member of it. It then consisted only of members of the English Branch Council. In 1867 members were added from Ireland and Scotland. He thought the Committee acted within its proper sphere.

Dr. PITMAN thought discussion of the Report should be deferred, in common courtesy, till after it had been read, and by consent of the Council the Registrar then read the following report:—

"The examinations in general preliminary education under the authority of the Royal College of Surgeons previously to 1875 were held in June and December. Since that time they have been held in March and September, because those months were found to be more suitable to the medical student, as they immediately precede the summer and winter sessions; and the convenience of this arrangement has been proved by the great number of candidates who have resorted to them. It is therefore important that preliminary examinations, suitable and accessible to intending medical students, should be held in those months. After the present year, the 'registration examination of medical students' by the University of Durham, and the 'examination in arts' by the Apothecaries Society of London, will be the only examinations in England which take place in those months. If the often repeated recommendation of the Medical Council, that the preliminary examination of medical students should be conducted by the National Educational and Examining Bodies, is to be carried out in England, it is essential that examinations suitable for intending medical students should be conducted at times convenient to them. The Committee would gladly have been able to report that the University Local Examinations and the Oxford and Cambridge School Boards Examinations are able to supply the deficiency. Those examinations are held in May, June, July, and December, which are the months most suitable to the several schools; and they will probably be more and more resorted to as avenues to registration by medical students; but the times at which

they are at present held are inconvenient to many medical students. The letter from the secretary to the College of Preceptors indicates that that body is willing to institute an examination similar to that which it has conducted under the authority of the College of Surgeons, and by means of local centres to render it more accessible to most medical students. The Committee therefore recommends that the Council should delegate to the Executive Committee to make arrangements with bodies willing to institute preliminary examinations suitable for medical students."

Dr. PITMAN moved, and Dr. HUMPHRY seconded, that the report be received and entered on the minutes.

Mr. TURNER thought the scheme referred to should be read and entered on the minutes also. This was agreed to.

#### INFAMOUS PRACTICE.

The case of Samuel Levenston, M.D., who was summoned before the Council, was fully discussed, counsel appearing on behalf of Dr. Levenston. The President explained that the Council's solicitor had considered the case, and had recommended the presence of an assessor to assist the Council. Mr. Ouvry read the summons to Dr. Levenston, charging him with unprofessional and infamous conduct in publishing certain disgusting advertisements. In explanation of the charge, Mr. Ouvry read two depositions, one testifying to the widespread distribution of filthy handbills, the other showing how poor people were mulcted of considerable sums of money for medicine declared to be worthless. For the defence, Dr. Levenston was examined as a witness, and declared the book had been out of print for twelve years. The handbill had been freely circulated for twenty years, and had never been checked. The work on debility was circulated by men aged 40-50, in the country only, and were ordered to be given to adult men only. The elixir was a strong tonic sold in bottles, for which a specific charge was made. He did not recollect supplying a parcel of medicine for £5 5s., but might have done so. He charged from 35s. upwards for parcels. The fee included medicine, consultation, and attendance. The medicine has been largely supplied, and with much benefit, as he could have proved had he been aware of the nature of the charge he was to meet. His counsel addressed the Council at great length, urging them to give the matter fair and impartial examination, and contending that Levenston's conduct was unprofessional perhaps, but not immoral. Mr. Ouvry addressed a few words to the Council in support of the charge, and strangers having been requested to withdraw, the Council proceeded to deliberate on the case. On the proposal of Mr. Simon, however, seconded by Dr. Pettigrew, the further consideration of the case was deferred to the following day.

Communications were then read showing the times at which the various preliminary examinations are held, and from the Privy Council Office concerning the regulations under which the several medical examinations are conducted. These were ordered to be entered on the minutes, and the Council adjourned.

#### SECOND DAY.—WEDNESDAY, APRIL 27.

The minutes of the preceding day were read, and with some slight alterations, were confirmed.

#### DR. LEVENSTON'S CASE.

Strangers having been requested to withdraw, the Council proceeded to consider the case of Dr. Levenston brought before it yesterday. The result was to convict the defendant, whose name was ordered to be removed from the Register.

#### PRELIMINARY EDUCATION.

Prof. HUMPHRY again read the Report of the Executive Committee on the preliminary examinations, and moved its reception. He proceeded to urge the importance of the question dealt with in the Report, since of nearly 1,000 students annually examined in England, more

than half were examined at the College of Surgeons. This showed how necessary it was to replace this examination with one equally convenient to students. Prof. Humphry pointed out that in pursuing this step, it had, at great pecuniary and other sacrifice, acceded to the Medical Council's recommendations. It was, therefore, important to yield considerations to the suggestions of the College contained in its letter to the Council. The Oxford and Cambridge School Board examination might be modified to bring it down to the standard of medical students; but this was uncertain, and hence the desirability of encouraging the College of Preceptors to institute a special preliminary examination for medical students. The Executive Committee thought it would be desirable to discuss whether the Council should retain some power over the proposed new examinations.

Sir WM. GULL seconded the motion. He thought the present evil of the profession was in its being stocked with inappropriate material. He insisted on a test which should exclude 33 per cent. of candidates. He thought the Council should exercise some supervision over the examinations it accepted for admission into the profession.

Mr. SIMON objected to assigning *carte blanche* to the Executive Committee on this or any question. The Council should reserve the full control of every matter coming properly within its functions. They should beware of seeking for a special preliminary examination for medical men; education and culture were common to all the educated classes. To approve a special examination of the College of Preceptors would be to perpetuate a vicious system, condemned by the action of the College of Surgeons in abolishing a special preliminary test of its own.

Dr. QUAIN observed that the Council seemed always working in a circle. They had again and again begged the corporations to give up their examinations. It would be monstrous to create a special examination of the College of Preceptors.

Dr. STORRAR recalled the fact that years ago a committee had sat to consider the question of preliminary education. It had been a severe struggle to secure that there should be a preliminary test at all. It was contended that medical students should not be required to show evidence of knowledge other than any schoolboy of ordinary ability might be expected to possess, that their examinations should be such as that demanded of any boy entering on the study of a learned profession. He desired to see accepted the national examinations, including that of the College of Preceptors; and not any special examination for medical students.

Sir JAMES PAGET explained there was no intention by the College to hold a special examination for medical students; but only such tests as are in conformity with the Council's requirements, to be held at convenient times.

Dr. STORRAR regretted that last year the Council had enlarged the list of subjects of preliminary examination. He respected the College of Surgeons, but beheld with dismay the extent of the examinations it held. He thought it would be advantageous to students, and again to the profession, to divide the preliminary examination into two parts. He hoped it would not be too late to go back a step, and do so. He asked if, in abolishing their examination, the College of Surgeons intended to ignore the other certificates now recognised.

Sir JAMES PAGET said the College would not accept these examinations; nothing, in fact, but registration by the Council. They reserved the right to act differently in exceptional cases, on their own authority entirely.

Dr. STORRAR continued, urging the adoption of a single standard, and the sweeping away of a large number of the 73 preliminary examining bodies recognised by the Council. He wished the Council would divide itself into two Committees, and for one day consider the requirements it wished to exact on account of preliminary education. The result would be beneficial in every way.

Prof. HUMPHRY asked permission, through the President, to amend his original motion to some extent.

Mr. MACNAMARA hoped the Executive Committee would observe the conduct of the examinations accepted by the Council. A *visa voce* test was essential to securing a good result; a wholly written examination being in no way satisfactory. The two combined gave the best result. He could say for the College of Surgeons of Ireland that that corporation would regard with the utmost jealousy any proposal to open the lists of accepted examinations. They had their own preliminary examination, which they were anxious to resign; but to do so was a difficult matter. At present Greek was a compulsory subject. He quoted from a letter from the Secretary of the Irish National Board of Education, in which it was declared that many subjects included as a *sine qua non* by the Council, are not, as a rule, included in the general preliminary examinations. For this reason the College of Surgeons resolve to retain its own examinations. A *visa voce* examination should be insisted on by the Executive Committee. No student had ever received a diploma from the Irish College of Surgeons who had not given proof of having passed an arts examination. It was true that this examination could be passed at any period of the curriculum.

Dr. PITMAN thought this question ought to be deferred till the discussion of the next motion.

Mr. MACNAMARA urged that he was in order, and again insisted on the necessity of *visa voce* examination.

On a division, Prof. Humphry's amended motion was carried.

#### UNIVERSITY CERTIFICATES.

The Executive Committee presented, through Dr. Haldane, the following report on the subject of communications which had passed between the Council and the two Universities of Oxford and Cambridge.

The Executive Committee having considered the foregoing letters, on the subject of preliminary examination, received from the secretary to the Oxford and Cambridge Schools Examination Board, the Secretary to the Cambridge University Local Examinations Board, and the chairman of the Board of Medical Studies of the University of Cambridge, as well as the communication from the vice-chancellor of the University of Oxford, on behalf of the medical committee of the hebdomadal council of the University, reports to the General Council:—

"It appears that if the new regulations with regard to preliminary examination passed during the last year's session of the Council be strictly enforced, none of the examinations conducted by the University of Cambridge, and the same may be said of those conducted by the University of Oxford, will fulfil the required conditions. It is not probable that those examinations could be altered into conformity with the new regulations; the Executive Committee therefore, bearing also in mind the recommendation of the Council, that 'it is desirable that the examination in general education should be left to the universities, and to such other bodies engaged in general education and examination as may from time to time be approved by this Council,' recommends that the examinations in general education conducted by universities should be accepted as heretofore."

Mr. TEALE seconded the motion.

Dr. STORRAR heartily approved the principle of the motion, but again protested against the Executive Committee considering important questions which by strict right should form subject of discussion in full Council.

Dr. HALDANE could not accept Dr. Storrar's proposal to amend the motion, as to do so might imply the acceptance of a censure, which he would not admit the Executive Committee merited.

Dr. STORRAR then moved as an amendment that "The university examinations be received as heretofore."

After a further discussion on the action of the committee,

Prof. HUMPHRY urged that the committee had done

no more than belonged to it to do; and that the fact of the Council having some time ago increased the remuneration of the committee, proved its intention of laying more work on its shoulders.

The PRESIDENT asked the Council not to forget the importance of the motion in the discussion as to its form. He thought the action of the Executive Committee tended to facilitate the Council's labours by preparing the work that lay before it, in accordance with a standing order dealing with the functions of the committee.

With Dr. Haldane's consent the amended motion was read from the chair.

Mr. MACNAMARA reminded the Council that last year certain subjects had been added to the list of those demanded; this motion undid all that was then done, for many university arts degrees included no word of mechanics and natural philosophy. Was the Council resolved to go back on its decision? And the same might be said of other subjects with equal truth.

Mr. TURNER said the point raised by Mr. Macnamara was a very important one, which he should have spoken of if it had not been broached. The motion, he thought, should be enlarged to express the opinion of the Council that in the cases where mechanical philosophy formed no part of the examination of university graduates, they should form the subject of a separate examination before registration.

Dr. STORRAR proposed the addition of a rider to this effect to the motion.

Dr. QUAIN wished to know who would ascertain the proficiency of students? He did not think the regulation could be carried out.

The PRESIDENT thought the assistance of examining bodies might be counted on to render the matter an easy one.

The motion as improved, was carried.

On the motion of Prof. HUMPHRY it was decided to forward a copy of the resolution to each body.

#### FOREIGN STUDENTS.

A report from the Executive Committee was read, in which it was pointed out that students from India sought to substitute Sanscrit for latin, &c., and which recommended the exemption of such candidates from further examination.

At Dr. Storrar's request, Prof. HUMPHRY explained that the Committee took the course it had to reduce the work by the Branch Council in adjudicating on every individual case of the kind.

Prof. TURNER pointed out that the passing of the motion would put the Scotch schools into a dilemma; it has been the invariable rule in Scotland to refuse applicants for registration from abroad, who have not complied with all the requirements. He ventured to think the nature of the Executive Committee's action should be discussed, and he proposed adjourning it till to-morrow.

Dr. STORRAR proposed that the standing orders respecting the business of committees be revised.

The PRESIDENT said such a motion had already been lodged by Dr. Pitman.

Dr. STORRAR wished to disclaim any desire to reflect on the members of the Committee individually.

#### THIRD DAY.—THURSDAY, APRIL 28.

The minutes of the second day's proceedings were read and confirmed.

#### FOREIGN STUDENTS.

Mr. TURNER continued his remarks on the importance of the matter dealt with in the report of the Executive Committee. Two considerations arose. (1) Is Latin to be a *sine qua non* of registration; and (2) Are licensing bodies to be allowed to pass unregistered students. The question recently came before the Executive Committee in connection with the application of two Indian students from Bombay, who sought to be admitted to the Edin-

burgh examinations on a certificate from which Latin was omitted. The Executive Committee acceded to the application, but subsequently referred the matter to the Council. Prof. Turner then cited numerous instances from the past minutes of the Scottish Branch Council, in which applications for admission as medical students were refused in those cases where Latin had not formed part of an elementary examination. English students had complained that the Apothecaries' Hall of London admitted Parsees to examination without showing evidence of proficiency in Latin. The complaint came from a student who dwelt on the injustice done to English students by passing Indians under such circumstances.

Mr. BRADFORD said no candidate was admitted to examination at Blackfriars who had not passed a preliminary examination in Latin.

Mr. TURNER said these letters had been submitted from the Edinburgh Royal College of Surgeons to the Apothecaries' Hall, and no reply had been received. The facts already presented, he urged, showed a want of uniformity regarding the requirements of different bodies in relation to Latin. He then pointed out correspondence from the Apothecaries' Society to the Executive Committee, in which it was said that in exceptional cases certain Latin authors are set to Parsee candidates, thus showing consideration had been given to special Indian candidates. The admission of unregistered candidates was a most important subject. Sir James Paget had said the College of Surgeons of England reserved the right of admitting specially exempted individuals for final examination. The Scottish Branch Council had resolved that registration should always precede admission to an examination, thus acting in direct disagreement with the Royal College of Surgeons. The decision of this question should be arrived at by the Council, but he thought a rigid rule, from which no deflection was possible, was unwise. No rule should be laid down which would exclude colonial and foreign students from qualifying in British schools. It would be fair to accept a test of general proficiency, and not to insist on any particular subjects, such as Latin, from those who had not studied it. Who, however, should have the power to relax the rules; the licensing bodies or the Council? He thought the power should be retained by the Council, or a committee of its body.

The PRESIDENT felt the Executive Committee would thank Prof. Turner for stating this difficult question so clearly. He thought it would be well to have frequent meetings of some committee, such as the Executive Committee, or a permanent committee, to which all such matters could be referred.

Dr. AQUILLA SMITH pointed out that Prof. Turner had dealt with two groups of students.

Dr. PITMAN moved, "That the General Council delegate to the Executive Committee, or to Branch Councils, power to make exception to the recommendations on education and examinations, in cases in which such exception shall seem to them to be reasonable."

Dr. QUAIN seconded this, and pointed out that to many foreign students (from Constantinople and the East), Latin is of no use, and it would be unfair to torture them with it.

Sir WM. GULL thought no corporation would admit students to examination without registration.

Sir JAS. PAGET assured Sir Wm. Gull that any continental practitioner already qualified could present himself before any licensing body. He thought the Council ought to retain the right of making exceptions, but not use it further than asking all corporations to report the exceptions they admit.

Sir WM. GULL having repeated his objections,

Mr. MACNAMARA pointed out that any qualified practitioner whose qualification is one of those accepted by the Council, can *demand* to be registered, and the Branch Registrar cannot, by the terms of the Act, refuse. It was competent to the Council to recommend examining bodies to admit only duly registered students, but it could do no

more. He added that in future the Royal College of Surgeons of Ireland determined to send every claim, for exception, on to the Branch Council for its consideration.

Mr. SPENCE thought the Branch Council ought to determine every such case, as was done in Scotland, the Royal College of Surgeons of Edinburgh invariably sending every case of the kind for its consideration.

The PRESIDENT read Mr. Turner's amendment, "That in cases where, for special reasons, candidates have not complied with all conditions of examination, exceptions be allowed on principles to be fixed by the General Medical Council."

The discussion was continued by Prof. TURNER and Mr. SIMON, the latter suggesting that a rider be added to existing recommendations, declaring them both intended for application to named exceptions. He thought all exceptions admitted should be reported to Branch Councils. Individual exceptions of home students should be most jealously regarded.

Dr. STORRAR could not remember any occasion on which the Branch Councils had found difficulty in dealing with such cases. He, like Mr. Simon, regarded exemptions with jealousy, even in the case of Indian students. These can reasonably be expected to pass abroad an equivalent examination, for in every colony, examinations, including Latin, were held. There is a risk of the examination system breaking down, if the Council pursued its present course. Exceptions might possibly arise, but every such case might fairly be relegated to the Branch Council for settlement.

Sir JAS. PAGET seconded Mr. Turner's amendment, which, being carried, was put as a substantive motion, and was also carried.

Mr. SIMON moved that the Executive Committee be requested to form rules under which exceptions be allowed. This was carried with the alteration that the name of Prof. Turner be added to the Executive Committee.

#### PRELIMINARY EXAMINATION.

Mr. SIMON moved: "The passing the second-class examination of the College of Preceptors, provided the candidate passes in the first division, may be taken to satisfy the requirements of the Council for preliminary general education." He pointed out that this examination is nearly as good as that required by the Council. Slight alterations only in the scheme would be needed. At present, algebra or geometry is required, and Latin is not obligatory. He would make both these subjects obligatory, and demand success in the first division, to qualify for registration. Mr. Simon then proposed a motion embodying these conditions, and Prof. Turner seconded it.

Mr. MACNAMARA feared that 70 per cent. was a very high standard to require; he would prefer accepting 50 per cent.

Dr. STORRAR said the Council had been in the habit of admitting the first certificate of the College of Preceptors, and it was fair to require a candidate from whom a second certificate is demanded, should present this in a high class.

Mr. SIMON admitted Mr. Macnamara's objection, and would be willing to accept the 1st or 2nd class certificate, i.e., 50 per cent.

In this amended form the motion was put from the chair, and carried.

#### DENTAL BUSINESS.

Dr. Haldane was elected a member of the Dental Committee in place of Dr. Andrew Wood, deceased. Communications were read from the British Dental Association, thanking the Council for its attention to the provisions of the Act. Letters were then read from qualified dentists requesting the Council to direct the insertion of surgical qualifications, in addition to the dental, in the Dentists' Register.

Dr. STORRAR moved: "That every registered dentist holding any of the surgical qualifications recited in

Schedule A of the Medical Act shall be entitled to have such qualification or qualifications recorded on the Dentists' Register as evidence of the possession of a higher degree of knowledge." He thought the Council, in honour, bound to defend the interests of the dentists, and also of the public, and it would be doing so by pursuing the course he suggested. He would not discuss the question of comparative dental qualifications, but he thought the possession of a surgical qualification proved a man's superiority as a dentist.

Mr. TURNER seconding the motion, proceeded to explain away an objection raised by Dr. Quain, to the effect that the question had been previously dealt with when a motion was passed to omit the columns for additional qualifications from the Dental Register. The possession of a surgical qualification, in addition to a special dental qualification, indicated a higher degree of excellence as a dentist, he thought, and it was unjust to those who were more than dentists, to deprive them of the degrees they had.

Dr. QUAIN saw no reason for omitting *medical* qualifications also. The Council had formerly resolved to add all higher qualifications in a separate column, but after obtaining Counsel's opinions on their power to act so, the column was decided to be omitted from the Register. There could be no reason for re-opening the subject.

Mr. SIMON thought it would be inconvenient and unjustifiable to add these higher titles. There was no reason to assume that a man, *quid* surgery, was a better dentist.

Dr. AQUILLA SMITH begged the Council to be cautious in coming to a decision on this question. The Register was especially intended for dentists; he found over 500 licentiates of dental surgery on the list, and the memorial addressed to them was signed by 30 only of these. He feared to grant their request would excite high feeling between the two classes who would then be on the Register.

Dr. BANKS agreed that it was a hardship that highly qualified dental practitioners should be denied the distinction contained in publication of their titles. He could not agree that surgery did not help in dentistry.

Dr. PITMAN said the Council had to determine what formed higher qualification in dentistry, not the law. It had then to determine whether the M.R.C.S. was such a qualification. Mr. Simon said no. It would be serviceable to know the opinions held on the subject by the surgical members of the Council.

Dr. SCOTT-ORR considered it a hardship to men to refuse them the registration of their higher qualifications immediately after their names.

Mr. TEALE agreed with Dr. Pitman that the Council must decide what was a higher qualification in dentistry, and that membership of a College of Surgeons was such a higher qualification.

Mr. SPENCE felt certain a qualified surgeon was far more fitted to practise dentistry than one with a dental qualification only.

Sir JAS. PAGET considered there could be no doubt that surgical qualification added materially to the fitness of a dentist to practise his profession. He thought dentists should be induced to qualify as surgeons, and would be so by seeing associated with themselves gentlemen possessing higher qualifications than they.

Dr. McCLINTOCK insisted that the wider and more comprehensive his education, the better qualified a specialist must be. He defended the proposition to add higher qualifications, and said it would be unjust to do otherwise.

Prof. HUMPHRY did not think the diploma of the Royal College of Surgeons a higher qualification in dentistry. The Council should be careful, lest it once more did that which it would have to undo again under Counsel's direction.

Dr. HALDANE, while sympathising with all said in favour of registering higher qualifications, could not vote for the motion.

Sir Wm. GULL thought medical, as well as surgical qualifications, should be registered. Surely, however, the L.D.S. was a higher *dental* qualification than M.R.C.S.

He felt that in a millennial period the dentists would be absorbed in the general register.

Dr. QUAIN moved that Mr. Ouvry be consulted.

Prof. TURNER thought the Council should have before it the case on which Counsel's opinion was framed.

Dr. STORRAR having replied to the argument against his motion,

Mr. OUVRY (solicitor) pointed out to the Council that by its own action it had erased all qualifications not dental from the Dentists' Register. The Act only admitted of licentiateships in dental surgery being registered, and precluded the admission on the register of any but dental qualifications in a separate column. The Council must determine what if any but dental diplomas conferred a higher dental qualification.

On a vote being taken on the motion, it was declared carried; 13 for, 5 against.

A motion that the additional qualifications be registered with the dental qualification in the same column, was then carried.

#### FOURTH DAY.—FRIDAY, APRIL 29.

Before proceeding to confirm the minutes, Mr. SIMON entered a protest against the decision arrived at the preceding meeting, to register additional qualifications on the Dentists' Register, this being illegal.

Dr. QUAIN said the former resolution on the point ought to have been rescinded by the Council before passing a new and opposite one.

The PRESIDENT recommended a motion to this effect for future consideration. He pointed out that whoever agreed with Mr. Simon could show they did so by voting against the confirmation of the minutes.

Mr. SIMON urged that Mr. Ouvry's opinion ought to be inserted in the minutes, and proposed a motion to that effect.

After further discussion,

Dr. QUAIN seconded the motion of Mr. Simon, which, being put to the vote, was lost, the numbers being 5 for, 10 against, 3 abstaining from voting.

Mr. MACNAMARA then proposed to add a paragraph to the effect simply that Mr. Ouvry was consulted. This was seconded by Dr. MCCLINTOCK, and after some discussion, was put and carried.

The minutes were then confirmed.

#### FINANCE.

The Finance Committee reported that the income of the General and Branch Councils for the year 1880 (ending January 1, 1881) has been £6,871 19s., an amount which exceeds the income of the year 1879 by £702 5s. The expenditure during the year 1880 has been £5,303 18s., which is less than the expenditure of 1879 by £116 9s. 9d. The income during the year 1880 has exceeded the expenditure by the sum of £1,568 1s.

The Dental Finance estimates show a probable future excess of expenditure over income amounting to £880, which must be met by drafts on invested capital.

Dr. QUAIN moved, Dr. AQUILLA SMITH seconded, the adoption of the report.

Mr. TURNER called attention to the serious outlook of the dental finances, and hoped that some means of meeting the difficulty would be arranged. The expenses seemed very large.

Dr. QUAIN said the Council was a very expensive piece of machinery, and the dentists must submit to the outlay, since they refused to accept the advice given them to manage their own affairs.

After some further discussion the report was adopted.

#### ANNUAL MEETING.

Mr. MACNAMARA moved, "That it is desirable to hold a stated meeting of the General Medical Council once in each year."

The desirability of this change, he thought, had been

indicated by the events of the present meeting. He did not in any way wish to curtail the power of the President as to convoking the Council, which, however, was clearly empowered to act as he suggested. The adoption of his plan would not affect the President's power at all. It was most desirable that the meeting should be held early in the year, for the consideration of any important Parliamentary questions as they arose. At that time an important occurrence (the appointment of a Royal Commission) had been announced; and this it might be desirable to consider. Mr. Macnamara deplored the inability of Dr. Houghton to attend the meeting in consequence of its being convened at so unsuitable a period, a time highly inconvenient for several members of the Council. If the meetings were held at stated times it would admit of arrangements being made in respect of it some time ahead. The earliest period of the year convenient he deemed the most suitable.

Dr. LEET seconded the motion.

Dr. BANKS said he had been requested by Dr. Houghton to express his extreme regret at being unable to attend the meeting by reason of his important engagements at the period its sittings extended over. For himself, too,

Dr. BANKS continued, it was a highly inconvenient time of meeting. He thought the proposal a desirable one.

Dr. STORRAR thought, in spite of the difficulties surrounding the subject, the selection of the times of meeting ought to remain with the President.

Dr. AQUILLA SMITH thought the motion quite unnecessary.

The PRESIDENT having spoken as to the difficulty of arranging a convenient time of meeting, the motion was, by permission, withdrawn.

Mr. MACNAMARA then moved: "That it be recommended to the several licensing bodies to institute examinations at the end of each year of professional study, which the student should pass before being permitted to enter on the subsequent year's course of study." The importance of this, he urged, could not be over-estimated. The principle had been admitted by the regulations of the Royal College of Surgeons in Ireland and other bodies, and by the recommendations of the Council, advocating the study of subjects at definite times. It was a common experience with teachers that students were diligent in the first, careless in the second and third, and hard-working again, to make up for lost time, in the fourth years. The hard and fast insistence on definite lines of study, as in France, was to be condemned, but it could not but be advantageous to gauge the annual progress of the medical student. The principle of the resolution had been always recognised by the Council, but the insistence on the final clause was that he especially called for. Without this test students pass on to further studies, without proving they have mastered the prior ones, thus necessarily multiplying the work remaining to be accomplished. Universal adoption of the motion would tend to make education thorough, and would be a great public gain, as it would tend to filter the student ranks, and throw out, at an early date, those unfitted to go on with a medical curriculum. Experience, Mr. Macnamara said, had taught him that numbers of men came to the study of medicine, who soon found themselves unfitted for it, and thus their parents were submitted to useless expense. Such men could not possibly be creditable acquisitions to the profession of medicine, which would be well purged of them, and would be thereby gradually raised in status.

Dr. MCCLINTOCK seconded the motion.

Mr. TRALE said the proposal could not be followed by many licensing bodies, because many of the candidates who come to them were already either qualified practitioners, or, at least, senior students.

Mr. SIMON would recall to the Council that in 1877 he proposed a recommendation bearing on the same subject. He approved the principle of the motion, believing that students should be examined at the end of each period of study. He hoped the Council would some time refuse to

allow time passed in higher studies to count until the preliminary tests had been complied with.

Mr. MACNAMARA thought the time opportune for such action as he proposed, especially as a Royal Commission was about to commence its sittings. He referred to Dr. Smith's expressions as to the impossibility of pursuing the plan at the College of Physicians in Ireland. He claimed an expression of opinion from the Council on the principle of the motion.

Prof. HUMPHRY approved the principle, but could not vote for the motion as it was framed by its proposer.

The motion being put to the vote, there were for it 2; against, 14.

#### PRELIMINARY SCIENTIFIC EXAMINATION.

A Committee, consisting of Dr. Haldane (chairman), Dr. Rolleston, Dr. Storrar, Mr. Turner, Dr. Hudson, and Dr. Humphry, appointed on the 11th of November, 1880, issued a letter to the various licensing bodies, requesting answers to the following questions:—

1. What amount of knowledge of the rudiments of natural science might be fairly required from intending candidates for the medical profession?

2. Should candidates, before being admitted to examination, be required to adduce evidence of having been specially instructed in natural science; or should proficiency, as ascertained by examination, be considered sufficient?

3. At what period should the preliminary scientific examination be passed? Should it take place before the commencement of the purely medical curriculum, or before the end of the first year thereof?

4. If a candidate have taken up a department of natural science, as an optional subject, at the preliminary general examination, should the fact of his having passed in it satisfactorily exempt him from appearing for examination on the same subject at the preliminary scientific examination?

5. In the case of candidates who have passed the preliminary scientific examination, what modifications could be made in the present medical curriculum and present professional examination?

The following report was presented by this committee:—  
Answers have been sent in by sixteen of the licensing bodies. The University of Dublin does not approve of the resolutions, "their principle being contrary to that of the present system of Trinity College, which they consider superior;" and the University of London enters into no details, but merely refers to its own regulations, as published in the Calendar of the University.

The other fifteen bodies have answered more or less in detail.

The following digest expresses generally the opinion entertained by these bodies with regard to the questions submitted to them.

#### 1. Subjects of Examination.

On this point the Universities adhere to their own practice, and express no opinion as to what should be required as a minimum qualification. There is more diversity of opinion on the part of the corporations. The College of Physicians of Edinburgh considers the present preliminary examination sufficiently extensive, but would make natural philosophy a compulsory subject; the College of Physicians in Ireland recommends an examination in the elements of mechanics, hydrostatics, physics, and chemistry; the College of Surgeons of England would encourage study in one or more branches of natural science; the College of Surgeons in Edinburgh recommends mathematics, as at present, elementary physics, and chemistry; the College of Surgeons in Ireland recommends physics, elements of chemistry, and botany; the Glasgow Faculty, physics, chemistry, and "perhaps an elementary knowledge of general biology;" the Apothecaries' Hall in Ireland recommends elementary mechanics, chemical physics, and the elements of zoology and botany.

2. *Should Proficiency, as ascertained by Examination, be sufficient? Or should Proof of Special Instruction be required?*

The Universities for the most part require proof of systematic instruction. The Corporations are generally in favour of the examination test alone. The Apothecaries' Society of London is of opinion that evidence of special in-

struction should be required. The Glasgow Faculty would recommend, but not require, it.

#### 3. Time of passing Examination.

The University of St. Andrew's, the College of Physicians Edinburgh, the Colleges of Physicians and Surgeons of Edinburgh, the Glasgow Faculty, and the Apothecaries' Halls in England and Ireland, recommend that the examination be passed before the commencement of the medical curriculum; the Colleges of Physicians and Surgeons in Ireland, during or at the end of the first year of the medical curriculum; the Universities of Edinburgh and Glasgow, not earlier than the end of the first year of the medical curriculum; the University of Cambridge, as soon as the student pleases, provided not less than three full years intervene between it and obtaining a degree or diploma.

4. *Should passing in a subject at the General Preliminary exempt from re-examination in the same subject at the Scientific Preliminary Examination?*

On this point the Universities would adhere to their present practice, which, in most instances, admits no exception, but the University of Edinburgh suggests: "If a candidate has already passed an examination in chemistry, botany, or geology, such as that required for a degree in science, this should *pro tacito* exempt him from further examination." The College of Physicians in Ireland would require the full scientific preliminary to be passed; the three Colleges of Surgeons would exempt (the College of Surgeons of England partially); the Glasgow Faculty, provided there are to be two examinations, would make the first literary, the second scientific; the Apothecaries' Society of London would require the examination in natural science subject to be compulsory, either at the preliminary general examination, or at a second or preliminary scientific examination.

5. *Modifications in the Medical Curriculum consequent on establishment of a Preliminary Scientific Examination.*

The Universities of Edinburgh and Glasgow and the Colleges of Physicians and Surgeons in Ireland would make no modification; the College of Surgeons of Edinburgh and the Glasgow Faculty would exclude chemistry, if passed at the preliminary examination, from the medical curriculum; the Universities of Cambridge and St. Andrew's, and other bodies, cannot reply without knowing what is to be the nature of the preliminary scientific examination.

From a consideration of the answers, of which an abstract has been given, it will be seen that there is a considerable difference between the views of the Universities, on the one hand, and of the Corporations on the other; the former adhering to their present standard, the latter keeping in view the danger of raising the standard too high. It may be expected that there will be a decided difference in the requirements for a degree and a mere licence to practise; and that the difference would consist, not merely in professional education and examination, but also in the standard of literary and scientific acquirements. Thus, while it is right that candidates for a degree should be required to possess a good general knowledge of biology, it does not seem desirable that knowledge in so wide a range should be required from every medical student. The Committee are of opinion that in the case of non-university students, instead of a special preliminary scientific examination, it would be better to carry out a Recommendation (31) of the Medical Council respecting a first examination, to be passed at any time before the end of the first year of medical study, and to include elementary mechanics (if not previously passed), chemistry and chemical physics, and elementary human anatomy or elementary biology. There is reason to believe that the first year, at least, of medical study is too often wasted, in consequence of the first examination, which, in many instances, does not take place till the end of the second year, being looked upon as something in the remote future; whereas the institution of an examination to be passed at an earlier period would necessarily give a stimulus to early exertion.

In conclusion, your committee would beg to recommend:

Firstly—That the natural science subjects remain, as at present, optional subjects at the preliminary examination in general education; forty-five months to elapse between that examination and the final examination, as at present.

Secondly, that the attention of those licensing bodies

which have not complied with Recommendation 31 (a) of the Medical Council be directed to that Recommendation; and that it be further recommended that the subjects of this first professional examination be:—

1. Elementary mechanics of solids and fluids, comprising the elements of statics, dynamics, and hydrostatics (unless an examination in that subject shall have been passed at the preliminary examination).

2. Chemistry and chemical physics (meaning thereby heat, light, and electricity).

3. One or more subjects of elementary biology, which may be elements of human anatomy, or of human anatomy and physiology, or of botany, or of zoology and comparative anatomy.

The Committee are of opinion that it is desirable that evidence of attendance on lectures and practical instruction in anatomy and chemistry should be required; but they do not think that this is necessary in the case of elementary mechanics. They would observe, however, that the Council have not hitherto issued recommendations relating to requirements of attendance on lectures.

D. R. HALDANE, Chairman.

Dr. HALDANE moving the adoption of this Report, explained the circumstances under which the answers from the licensing bodies were sought and obtained. He had feared that the addition of new subjects to the examination requirements would seriously embarrass already over-burdened students. He quoted some statistics dealing with examinations in Scotland in preliminary knowledge, from which it appeared that the greater number of failures were in subjects of which it was sought to raise the standard. He had felt it almost a hopeless task to do this by increasing the difficulties surrounding the student already. The Committee thought there should be a difference in the amount of knowledge required from candidates for a degree and candidates for a diploma. This difference should be in the way of general scientific education, however; the professional attainments ought to be no lower in the one case than in the other.

Mr. TEALE seconded the adoption of the Report, and thought it desirable that evidence of a training in physical science should be demanded from medical students. Still it should be carefully considered how far it would be wise to institute what really was a new examination. It was possible that examinations when multiplied did harm, the strain they entailed on students and schools withdrawing the energy of teacher and student alike from essential studies. The plan proposed by Mr. Macnamara for requiring students to present themselves again and again at much expense and toil would be an unwise proceeding, especially since the danger of unduly imposing on the powers of the student is a serious one.

A desultory discussion on the first recommendation took place, doubts apparently existing as to the meaning of "natural science subjects," which it was explained implied the scientific subjects optional at preliminary general examinations.

Dr. PITMAN then moved that the Report be referred back to the Committee for revision preparatory to future consideration.

Dr. FERGUS seconded the amendment.

Mr. MACNAMARA said it was most important to discuss the Report then, especially because of the recommendation deferring the new regulations till 1882, and because everything possible should be done before that time to explain what is to be done in view of that. First, this resolution should be rescinded if the report is to be *sub-judice*.

Dr. FERGUS urged there was nothing in the proposals bearing on existing regulations printed in the students' Register.

Prof. HUMPHRY said that replies had been received from all the corporations but two, in the expectation that the Report on them would be presented at that sitting of

(a) Regulation 31.—"It is desirable that an examination in the earlier subjects of professional study should take place before the end of the first year of professional study."

the Council. He thought, therefore, the Council ought to adopt the Report forthwith, and decide on its clauses.

Dr. BANKS supported Dr. Pitman's proposal.

The debate was then adjourned.

#### FIFTH DAY.—APRIL 30TH.

The minutes were read and passed.

Dr. QUAIN then asked the President, with a view to the order of business, a question founded on the following facts:—

A resolution was adopted by the General Council, on March 26, 1879, having reference to an important feature in the formation of the Dentists' Register;

A resolution entirely altering the resolution referred to was adopted by the Council on April 28, 1881;

The question is: Is it or is it not correct, as a matter of order, "that an original resolution should be rescinded before a new resolution is proposed?"

The PRESIDENT replied that it would generally be more strictly regular to follow the course of rescinding the original resolution. But the new resolution being in itself a rescinding of the original resolution, there seemed no necessity for a formal act to the same end. Dr. Acland said he had been asked by the Registrar whether diplomas not included in the dentists' register were to be admitted as "other qualifications," also what were registrable surgical qualifications, e.g., was the L.R.C.P. Lond.?

Dr. PITMAN moved that the President be authorised to answer the questions after consultation with the Council's legal adviser.

Dr. HALDANE seconded the motion.

Dr. QUAIN pointed out the absurdity of the motion, since the Council had already rejected the advice of their solicitor.

Mr. SIMON, Dr. STORRAR, and Mr. TURNER (who claimed that it was unjust to the Scotch universities to refuse their M.B. as a surgical qualification as much as the L.R.C.P. Lond.) spoke.

Sir W. GULL continued the discussion, moving that every qualification, medical or surgical, be included in the Dentists' Register.

Dr. SCOTT ORR seconded the motion.

The PRESIDENT recalled the attention of the Council to the business before it, viz., consideration of Dr. Pitman's motion to refer the matter for consultation between the President and the Council's solicitor.

Dr. STORRAR said he should vote against the motion.

Mr. TURNER thought the motion referred to matters of form and not of principle, and was in no way antagonistic to the former resolution; and the suggested conference was a proper way to end the difficulty.

Dr. QUAIN objected that to admit Sir W. Gull's motion would be destructive of all order in their proceedings, and would go to upset the previous decision.

After further discussion, which was eminently confused, and amid which it was hardly possible to make out the points on which the speakers were dwelling.

Mr. SIMON suggested that pending further proceedings the Council should defer any action in the matter. They could not define what was and what was not a surgical qualification. He had no intention of asking the Council to rescind its resolution, but pending further consideration of the subject, the Council ought to refrain from carrying action any further.

The PRESIDENT entered into an explanation of the circumstances under which the questions were proposed to him by the Registrar. The latter foresaw that difficulties must arise, and he wished for guidance in settling them.

Mr. MACNAMARA said he had pointed out, in private, that this difficulty must arise; clauses 26 and 27 of the Medical Act gave the Registrar the power to decide as to the admissibility of any diploma for registration, appeal from him to the Council being allowed. And further, the Medical Register is the only authority in proof of possession of a qualification admitted by the Act.

Mr. TURNER thought the clauses mentioned referred only to persons about to give evidence in a court of law.

Sir JAMES PAGET said the Council having decided that surgical qualifications only should be registered, the only question remaining was therefore What is a surgical qualification? This should be decided by a legal opinion.

Prof. HUMPHRY said there were no such things as surgical qualifications under the Act, which recognised only qualifications to practise.

Sir W. GULL said his motion would meet the difficulty since he proposed to admit any registrable qualification. The motion of Dr. PITMAN was then put and carried.

#### PRELIMINARY SCIENTIFIC EXAMINATION.

The adjourned debate on the following motion by Dr. Haldane, seconded by Mr. Teale, with amendment thereto, moved by Dr. Pitman, and seconded by Mr. Fergus:—

Motion:—"That the following recommendation of the Committee be adopted: 'That the recommendations of the Council at present in force in respect of the Natural Science subjects in the Preliminary Examination be not at present changed.'"

Amendment:—"That the Report be referred back to the Committee, with a request that after they have received and considered the answers from all the Medical Authorities to which certain questions have been addressed by the Committee, the Report be received and sent to each member of the Council, preparatory to its consideration at the next Session of the Council."

Dr. HUMPHRY said the Committee was prepared not to press the consideration of the Report at that meeting, but he felt very sorry that this course was necessary.

Dr. HALDANE echoed Dr. Humphry's regret that the discussion should be adjourned, and would ask to withdraw his motion.

Mr. MACNAMARA objected to the withdrawal; the reasons given were insufficient. Only two bodies had failed to reply, and both were well represented in Council.

Prof. HUMPHRY said this was not the reason, which was that the Council was unwilling to discuss the question in that stage.

Mr. MACNAMARA continued that it would be a serious matter to let the public assume the Council was unable or unwilling to terminate the great question which had been so long before it. A short time would settle it, and it would do much harm to leave it. Students were left in confusion as to that which was to be required of them, and teachers also were in doubt as to the requirements, about which there could be no certainty until the question was settled. The Royal Commission would have to be told that after many years the one great question was still unsettled, and it would do very much to damage their reputation in the public mind. In the interests of students, of the Council, and the public, a prompt settlement was demanded.

Sir W. GULL did not think the matter so easy as Mr. Macnamara supposed. The discussion must be thorough and exhaustive. It would be better to defer the matter.

Mr. SIMON was proceeding to speak when he was stopped by a discussion as to the business before the house, at the conclusion of which Mr. Simon was judged to be in order, and proceeded to express his indignation at the interruption he had been subjected to. He suggested that, the Council feeling itself unable to go into detailed discussion on the motion, the principle of it at least might be adjudicated on. This principle, that of lightening the medical curriculum of what might be disposed of before its commencement, the Council might discuss without occupying a great amount of time. He suggested that licensing bodies should be required to demand from their candidates the passing of a preliminary scientific examination before the end of the first year of purely medical studies.

Mr. TURNER asked what "medical curriculum" included?

Mr. SIMON thought each licensing body would decide for itself what was a purely medical curriculum.

Sir JAMES PAGET approved the proposal of Mr. Simon.

Dr. PITMAN begged Mr. Simon to acquit him of any intention to disturb him when he, a short time before, rose to a question of order. He would withdraw his own amendment, and support Mr. Simon's proposition, if put in the form of a motion.

The amendment of Dr. Pitman having been withdrawn by consent, Mr. Simon's proposition was put as an amendment to Dr. Haldane's motion, seconded by Sir James Paget, and carried.

#### COURSE OF BUSINESS.

Dr. STORRAR moved that the *standing orders* as regards the Executive Committee be reconsidered by the Council. The necessity for this was, he thought, proved by recent events; the Committee should act on its own responsibility only in matters of urgency. The Executive on several occasions had assumed functions not properly belonging to it.

Especially in respect of the way in which the dental question had been treated, had dissatisfaction been aroused among the educated dentists outside. The minutes of the Executive Committee, and of the General Council, were alike without record of the way in which counsel's opinion as to the manner of admitting on to the Dental Register was obtained. Moreover an entirely new counsel was engaged, and the report was sent out only twenty-four hours before the meeting of the Council. This was marked, "Private, for use by Members of the Council only;" and thus he was unable to show it to those most entitled to know the proceedings of the Council concerning dentists. The Council, when it met to discuss the Dentists Register, as coerced into action, and there was a wide-spread impression in educated circles—an impression that Sir Farrar Herschell's and Mr. Muir Mackenzie's opinions were unsound, and that there was a legal remedy against the Council's action regarding dentists, Dr. Storrar could not understand Dr. Quin's allusion to amateur legislation concerning the Dentist Bill, for all the alterations in the Dental Bill were introduced by the Government. Dr. Storrar disavowed any personal feeling in bringing forward his motion. It had been called forth by the proceedings of the past few months, against which there might be very just complaint made. He would be willing to withdraw the motion.

Dr. PYLE seconded the motion, and agreed with all that Dr. Storrar had said. He thought the Committee had usurped the functions of the Branch Council.

Dr. AQUILLA SMITH defended the action of the Executive Committee.

Dr. STORRAR asked leave to withdraw the motion, and was permitted to.

A condensed account of the requirements of the Swiss medical examinations was presented by a committee appointed to report on them, and adopted, as also certain alterations in the *standing orders* proposed by the Business Committee.

#### REGISTRATION REGULATIONS.

The Committee appointed April 28, 1881, to prepare for the consideration of the Council Draft-Rules defining the classes of cases in which exceptions may be allowed to the recommendations of the Council as regards the examination in general education and registration, reported as follows:—

"That exceptions may be made in the case of a student from any Indian, Colonial, or Foreign University or College, who shall have passed the matriculation or other equivalent examination of his University or College, provided such examination fairly represents a standard of general education to that required in this country.

"Before any such student can be registered, sanction must be given in Scotland and Ireland by the respective Branch Councils of those countries, and in England, either by the Branch Council for England, or by the Executive Committee, as may be most convenient.

"In case a Graduate in Medicine of an Indian, or Colonial, or Foreign University, or a student who, having completed the full time required by the Medical Council, and having given satisfactory evidence of general education, shall have spent the whole or three-fourths of that period at an Indian, Colonial, or Foreign University, is admitted to examination by any of the licensing bodies, the licensing body is requested to report the particulars of each such case to the General Medical Council."

Mr. MACNAMARA inquired if this covered every case in which exception should be made.

Dr. PITMAN said it referred only to Indian and Colonial students.

Mr. MACNAMARA said that it was important to know, because in Ireland occasion sometimes arose to necessitate exceptions to the usual rules.

In a slightly modified form, which in no way affected the meaning of the clauses, the report was carried.

THE annual rates of mortality last week in the principal large towns of the United Kingdom per 1,000 of the population were—Hull 17, Portsmouth 17, Norwich 17, Salford 17, Bradford 17, Oldham 18, Brighton 19, Leicester 19, Bristol 19, Birmingham 19, Leeds 20, Sunderland 21, Manchester 21, Sheffield 21, London 22, Edinburgh 22, Nottingham 22, Glasgow 23, Wolverhampton 25, Liverpool 27, Plymouth 28, Newcastle-on-Tyne, 29 Dublin 32.

## Clinical Records.

### CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST.

*A Case of Cancer of the Lung.*

Under the care of Dr. BIRKETT.

Reported by SIDNEY DAVIES, B.A., Clinical Assistant.

JOSEPH P., æt. 52, traveller, was admitted into Victoria Park Chest Hospital on November 30th. The patient had a careworn aspect, and a face well marked with furrows. He had had no previous illness of any importance, indeed, he appeared to have enjoyed good health until twelve months before admission, when he was troubled with giddiness in the head, which he attributed to hepatic disorder. His family history was not very lucid: his father and mother both reached the age of 72 before they died. He had three sisters living, in good health, one brother had died from alcoholism, and one sister from what he described as cancer.

The patient gave the following account of his illness:—About Christmas, 1879, he caught cold, and had several attacks of rigors. He was in bed for two weeks with pleurisy of the left side. He recovered sufficiently to be able to return to work, but the pain in the side continued. He had progressively wasted. He had been troubled with night perspirations; there had been no hæmoptysis. About two months before admission increasing cachexia had obliged him to leave work.

On admission the patient presented a markedly cachectic appearance; his face was anæmic; the fingers were not clubbed; tongue clean; bowels regular. Respirations 20 per minute. He had a bad cough, and copious frothy sputa. The pulse beat 115, tension low, compressible. The artery was thickened. Temperature in the evening, 101.5. The urine was acid, specific gravity 1015, and contained urates, but no albumen. The patient complained of sleeping badly, and that he was unable to lie on the right side. The veins on the left side of the neck were swollen, and the left arm and left side of the chest were œdematous, pitting on pressure.

Dr. Birkett made a physical examination of the chest the day after admission, with the following result: On the right side loud compensatory breathing; at the left apex the respiration is confined to the large tubes. In the left axilla absence of breathing and vocal resonance; tympanitic resonance over the 2nd costal cartilage, and behind along the left side of the spine down to the 6th dorsal vertebra. Some respiration heard a little below and inside the angle of the scapula. Over the rest of the left lung there was almost complete dulness, and absence of breathing sounds, and vocal vibrations. There was, however, tympanitic resonance in the left axilla, extending downwards from two inches below the horizontal line of the nipple. Over it there was absence of breathing and vocal resonance. The cardiac sounds were normal, but heard best on the right side of the sternum. The only visible cardiac pulsation was in the epigastrium. The following circumferential measurements of the chest were made:—

Left side, 2 in. below nipple	...	...	17½ in.
Right do. do	...	...	17¼ "
Left 3 in. above nipple	...	...	18¼ "
Right do. do	...	...	17¼ "

The note made of the patient's condition on December 3rd was—Poor appetite; tongue clean; bowels open: breathing a little better.

On the 7th—Cough troublesome; weakness increased; tongue very pale; bowels irregular.

With the view of clearing up the diagnosis, paracentesis thoracis was performed a few days after admission, but no fluid was obtained.

The patient died on the 13th.

A post-mortem examination was made 20 hours after death, and revealed the following condition:—Rigor mortis well marked; body much emaciated. On opening the chest about a pint of purulent grumous offensive fluid poured out from a breach on the surface of the left lung.

Dr. West examined the left lung on the following day, and described it as follows: Pericardium universally thickened. At the base one or two bosses project into its interior. All the bronchial glands of the left side are hard, white, and uniform in appearance. From the surface of the glands a creamy

juice may be scraped; all trace of distinction between the separate glands is lost; and from the mass formed by them, radiating processes entered for some distance into the upper lobe. Through this mass the vessels and bronchi pass, and have their lumen constricted; this is especially the case with the large blood vessels. Starting from this mass is traced a considerable thickening of the pleura and pericardium. This thickening is, in the neighbourhood of the tumour, evidently due to an infiltration of the same nature as the tumour. The rest of the upper lobe of the lung is riddled with cavities, most of them of large size, the trabeculae of which are deeply pigmented. The whole lower lobe appears grey on section, riddled with cavities of small size, filled with a puriform fluid, and is in such a state of disintegration that a section can hardly be made.

The other organs all appeared to be healthy, no other abnormal growths or enlarged glands being found.

*Diagnosis.*—Malignant tumour of mediastinum and lung; secondary pleurisy and pericarditis; phthisis. A microscopic examination showed that the new growth and puriform fluid consisted principally of round, granular, and multinucleated cells, varying considerably in size.

## Department of Lunacy.

### SCOTTISH NATIONAL INSTITUTION FOR THE TRAINING OF THE WEAK-MINDED.

THE Scottish National Institution for the Education of the Weak-Minded, which was founded about twenty-five years ago on the model of Earlswood, after passing through a somewhat inglorious infancy has become famous during the last ten years under the tutelage of Dr. Ireland. The opportunities which it afforded for the study of the varieties of mental imperfection were taken advantage of by Dr. Ireland immediately on his appointment to its chief charge, and the results of the researches which he conducted in its wards were soon given to the world in his book on Idiocy and Imbecility. This work, which at once became the standard English authority on the subject, and which has received gratifying recognition on the Continent of Europe, not only reflected credit on Dr. Ireland, but brought useful notoriety to the establishment over which he presided. Children of defective intellect were sent to it from England and the Colonies, and it bade fair to become the Rugby or Winchester of the weak-minded. Unhappily, however, its promising prospects were soon marred. The celebrity of Dr. Ireland has suffered no eclipse, but a notion has gone abroad that he has not received adequate support in his management of the establishment, which has become somewhat disorganised in consequence. To public institutions as to nations *prestige* is the breath of life, and any loss of confidence in their administration is sure to act prejudicially on their usefulness. It is not therefore to be wondered at that the rumours which have been in circulation for some time as to the condition of the National Training Institution at Larbert have checked its rising fortunes, and caused a falling off in subscriptions and in the admissions of pupils of the paying class. That these rumours have not been altogether idle and unfounded is now apparent, for Dr. Ireland has tendered his resignation of his office as Medical Superintendent, and the Directors have appointed as his successor the governor of a provincial poorhouse in Scotland. A board of directors that could take such a step is evidently not erring for the first time, but has become expert in blundering, and full justification is now given for the belief that the school has not been under judicious guidance, at least since the present board came into office. It would be interesting to know the constitution of the meeting of directors at which this egregious appointment was made, and the process of

reasoning by which a body of gentlemen brought themselves to believe that bumbledom affords the best training for the delicate task of teaching "the young and stunted idea how to shoot." If representative government prevailed in the Lerbart School, or if the idiots themselves had been asked to nominate their own preceptor, we could understand the selection made; but how a committee of presumably intelligent and benevolent men have come to ignore the relation of medical science to the education of the weak-minded surpasses our comprehension.

The subscribers to the Scottish National Training Institution have, it seems to us, a duty to perform, and that is, to inquire thoroughly into the working of the institution for the last two years, and into the circumstances which have eventuated in Dr. Ireland's resignation, and to undo the mischievous action of the directors, by placing at its head without delay an able and experienced medical man. It is no small misfortune to the institution to have lost the services of Dr. Ireland, when he is still vigorous and capable of doing it good services, but it will be ultimate ruination for it to be left without that medical guidance which ought to pervade and regulate its every department, and under the control of a lay governor who, however intelligent and well-disposed he may be, can know nothing of the elaborate system by which modern science strives to evolve imperfectly developed mental powers and to promote growth in stunted brains.

Dr. Ireland has been presented by the directors with an honorarium of £500 out of the funds of the institution, in recognition of his invaluable services. If his services have been invaluable, they have been so in virtue of his medical attainments, and it is a somewhat ironical proceeding after making such a grant on such a ground to appoint as his successor a person who is destitute of medical knowledge.

## Transactions of Societies.

### OBSTETRICAL SOCIETY OF LONDON.

WEDNESDAY, APRIL 6, 1881.

Dr. MATTHEWS DUNCAN, President, in the Chair.

#### DERMOID CYSTS.

Mr. KNOWSLEY THORNTON showed a dermoid cyst of the left ovary which had been entirely twisted off from its pedicle, and had become attached to the right side of the omentum. The patient first came under his care seven years ago with a doubtful abdominal tumour. She had since had four children, and during the last pregnancy the tumour gave her great pain. On April 2nd Mr. Thornton removed the tumour, together with a cystic tube, the remains of the twisted pedicle on the left side, and a cystic right ovary.

Mr. ALBAN DORAN showed microscopic sections from a dermoid cyst removed by Mr. Thornton from a woman, *æt.* 41. The wall consisted mainly of patches of true skin, with sebaceous glands and hair follicles. There were tooth-like bodies which proved to consist of cartilage. Small secondary cysts projected from the inner wall. In certain long narrow cavities in the subcutaneous tissue was seen well formed mucous membrane, having a perfectly cylindrical epithelium, with numerous involutions.

#### FETAL MONSTROSITY.

Mr. DORAN showed also a female fœtus which displayed extreme arrest of development of the genito-urinary tract. It was born at the seventh month, and breathed for a quarter of an hour. There was ectopia of abdominal viscera, club-foot, and spina-bifida. The bladder consisted of two lobes, and between them superiorly the intestine opened from above. The ureters were impervious. On the right side was a Fallopian tube, and tubular thick-walled uterus,

ovary atrophied; on the left an ovary and Fallopian tube, the uterus being an impervious cord.

#### CALCULI EMBEDDED IN FEMALE URETHRA.

The PRESIDENT showed several small pelvic acid calculi which had been removed from the wall of the female urethra in which they had become imbedded.

#### FALLOPIAN GESTATION.

Dr. GODSON showed the uterus, &c., of a woman, *æt.* 25, who had died in the Dorking Infirmary. Mr. Hopcroft, who sent up the specimen, could give no history, except that the woman was believed to be unmarried, and was in a dying state when admitted. Two pints of blood were found within the peritoneum. Old adhesions attached omentum, &c., to the uterus; both Fallopian tubes were dilated and tortuous. The outer end of the right tube enclosed a fœtus, of about six weeks development, in a fleshy mass containing villi. He thought the adhesions might have been due to gonorrhœa.

#### ADJOURNED DEBATE ON DR. BARNES DEBATE ON "MISSED LABOUR."

Dr. INKSON related the case of a lady who, when three and a-half months advanced in pregnancy, underwent great fatigue in travelling in India. After this there was no increase of size, but menstruation did not recur. About the time that labour should have taken place, she took a long ride on a restive horse; expulsive pains were induced, and an oval mass, containing a very small fœtus, came away.

Dr. EDIS said that several instances had been recorded by different authors, as Simpson, Meigs, and Atlee, in which gestation had been prolonged for one, two, or three months beyond the normal time. But in many such cases there was strong presumptive evidence that they were really instances of extra-uterine gestation, the supposed cervix being really a fistulous opening. Dr. Muller, after investigating forty-five cases of alleged missed labour, concluded that "there does not exist an authentic observation of retention of the fœtus within the womb beyond the term of ordinary pregnancy. In this conclusion he fully agreed, unless Dr. Barnes' case were an exception, but even this might have been partly interstitial, and not an ordinary extra-uterine pregnancy. In some cases in which the labour was obstructed by contraction of the brim or other causes, the uterus ruptured, the fœtus passed through the rent and became encysted, and was afterwards disintegrated and expelled.

Dr. GALABIN had met with a case of supposed missed labour, which tended to confirm the view that many cases were really instances of extra-uterine foetation. There was an effort at labour at full term, and he saw the patient two months later. There was then a sanguineous somewhat offensive discharge from the vagina, and the patient's condition had become grave. A catheter passed through the cervix into a cavity resembling the uterus, and gave exit to a fluid like that which had escaped from the vagina. After dilatation of the cervix by a tent, the breech of the fœtus could be felt presenting through a round opening which seemed to be the internal os. This turned out to be an aperture in the uterine wall at the point at which it was sharply retroflexed, and the gestation proved to be abdominal, the sac lying in front of the fundus. If no autopsy had been made, all who saw the case would have continued to suppose the fœtus intra-uterine.

Dr. HAYWOOD SMITH remarked on Dr. Godson's observation that menstruation had not taken place in consequence of the presence of the arrested fœtus, that it was an interesting question why such should be the case, as the fœtus ceasing to grow and so pregnancy proper ceasing, why did menstruation not recur? for it was probably owing to its non-appearance that the ovum was not thrown off.

The PRESIDENT said that, for his own part, he believed in the occurrence of protracted gestation and missed labour. The probability of their occurrence was much supported by the facts that they occurred in the lower animals, and that missed abortion, or missed miscarriage, occurred certainly in women. He did not think the occurrence of labour premonitions a necessary part of missed labour. In a case which he had seen and published in his "Clinical Lectures," there were no phenomena of labour till the evacuation of the uterus was undertaken artificially. In the best case of protracted gestation which he had seen and published there was a beginning of labour at full term, and labour came on spontaneously some weeks later. He thought the term

lithopedion, at present often used as synonymous with mummified fœtus, should be better defined. The fœtus never became calcified like a uterine fibroid, but calcification affected only the membranes, and sometimes the adjacent parts of the fœtus.

Dr. GONSON called attention to a case which came under his observation at St. Bartholomew's, which formed the basis of a paper by Dr. Greenhalgh on "Missed Labour," in the eighth volume of the Hospital Reports. The case was one of "missed abortion," and not "missed labour!" and the head of the fœtus should have been described as four and a-half, not of six, months development.

Dr. BARNES, in reply, said in reference to Mr. Spencer Wells' suggestion that the pregnancy might have been intra-mural, that intra-mural gestation generally ended by a fatal cataclysm at the 2nd or 3rd month. Dr. Roper's suggestion was ingenious, and might apply to some cases, but not to the one before the Society. The rhythmical action of the uterus could not be expected to be detected when the uterine contractility was impaired after the death of the fœtus. He would make a point of studying Dr. Duncan's cases. Meantime he thought that protracted gestation for an indefinite time required better proof than we possessed. He thought the term "missed abortion" a singularly unhappy one, and that the term "concealed" or "incomplete abortion" was much to be preferred. He could not agree with Dr. Duncan that the terms lithopedion and mummified fœtus were commonly used as synonymous. A "stone-child" should at least be stony, and the distinction was the more important since Cruveilhier had insisted, rightly as he believed, that a lithopedion was never found in the uterus.

Dr. HEYWOOD SMITH ON

#### A CASE OF DELIVERY THROUGH AN IMPERFORATE VAGINA.

The patient was 31 years old, married ten years, pregnant for the first time. The vagina was only 1½ inches long, and was completely closed by a roof of the normal thickness of vaginal tissue. This was congenital, and there was no cicatricial tissue. Her mother, a trained nurse, was aware of the malformation. One and a-half years previously she had consulted Dr. Edis for leucorrhœa, and he failed to detect the slightest orifice in the vaginal roof, though the patient menstruated, but with pain. The author had been called to see the patient at the British Lying-in Hospital, when she had been in labour thirty hours. On admission the urethra was so patent as to admit nearly two fingers, and from the husband's account coitus probably took place per urethram. The vaginal roof was lax, as the head was arrested at the brim. The os was completely dilated, and the bones of the head had begun to overlap. A careful examination failed to discover the slightest depression, or any indication as to any aperture, however small. The patient was therefore placed under chloroform, the vaginal roof was picked up with forceps, and a cut made at once with scissors directly through it, when, the finger being passed through the aperture thus made, the head was felt; the opening was then enlarged by tearing with the fingers until a passage was formed large enough for delivery, which was speedily effected by the long forceps, and a living female child extracted. The patient made a good recovery, and examination last December showed a normal vagina, with but a slight constriction, not at all hard, formed by the remains of the previous vaginal roof. The author quoted other recorded cases, amongst them one by Dr. Isaac Taylor, of New York, almost the counterpart of his own, except that the advancing head pressed downward upon the vaginal roof until a slight depression revealed itself, which was scratched through, and the opening dilated. There was a question of interest as to the mode of impregnation in the present case—whether it was through some undiscovered aperture, through which menstruation also took place; or whether there existed some slight fistula between the bladder and the upper chamber of the vagina.

Dr. PERCY BOULTON ON

#### A CASE OF IMPERFORATE VAGINA.

The patient was aged 18, married. Catamenia was always very painful, and was followed by "green waters" for several days. The vagina was found to be a *cul-de-sac* about one and a-half inches deep, and no opening whatever could be felt. An examination was made under chloroform, and a dilating speculum introduced. On either side of the vaginal terminus a small opening was then found, through

which a probe could be passed. The openings were dilated with tangle, and there was then found (1) a normal uterus; (2) a bipartite vagina, the upper portion being duplex, separated by a septum which formed a triangle with its base downward. A small communication between the two was found close up to the vaginal neck. The central block was divided by passing whipcord round by a sound having an eye at the end, and attaching it to an *écraseur*. A vulcanite plug was worn for three weeks, and the patient then went home well.

Dr. BARNES said that Oldham had long ago pointed out that in some cases of absence of vagina the urethra was largely patent, and this without having served for intercourse. It was not necessary to postulate a fistulous communication through the bladder. There was, no doubt, a small aperture, which had become closed after impregnation.

Dr. ROUTH noted the patient was treated during her pregnancy for leucorrhœa. He thought there might have been an opening allowing impregnation prior to the vaginitis which was afterwards closed by this inflammation.

Dr. BOULTON, in reply, said he thought that in most, if not in all, cases of apparently imperforate vagina in which menstruation or pregnancy occurs a pin-hole opening exists.

### ODONTOLOGICAL SOCIETY OF GREAT BRITAIN.

MONDAY, APRIL 4TH.

Mr. THOS. ARNOLD ROGERS, President, in the chair.

The meeting was at once made "special" for the purpose of considering an alteration in the Bye-laws, to the effect that in future no one should be eligible as a candidate for the membership of the Society unless he was either a licentiate in dental surgery, or a qualified practitioner of medicine or surgery, or possessed such a diploma or degree as the Council might approve. It having been pointed out by the President and Dr. Walker that the adoption of this regulation was a necessary consequence of the altered status of the profession which recent legislation had brought about, the resolution was agreed to without opposition.

#### CASUAL COMMUNICATIONS.

Mr. HENRY SEWILL related a case in which paralysis of the parts supplied by the inferior dental nerve followed the extraction of a lower wisdom tooth. There was complete anaesthesia of the skin of the lip up to the middle line in front, and all the teeth on that side were completely insensative. He had ventured to give a favourable prognosis as regards the restoration of sensation.

Mr. COLEMAN mentioned a similar case, in which sensation had not been completely recovered, even after the lapse of two years; whilst

Mr. BROWNE-MASON, of Exeter, said that in a case which had occurred in his own practice the paralysis passed off in a few weeks.

The PRESIDENT remarked that it was important that such cases should be reported, since they were sometimes made the ground of an accusation of unskilful treatment.

The paper of the evening was read by Mr. STOCKEN,

#### ON THE VALUE OF CERTAIN REMEDIES IN THE CONSTITUTIONAL TREATMENT OF INFLAMMATORY CONDITIONS OF THE VASCULAR TOOTH STRUCTURES, AND OF NEURALGIA ARISING THEREFROM.

The remedies to which Mr. Stocken specially directed attention were chloride of ammonium, sulphide of calcium, and gelseminum. He had selected these because the knowledge of their action was not so general as that of many other agents. He gave a full description of the therapeutic effects of these drugs, indicating the class of cases in which each would be likely to be most serviceable. The conclusion was that in simple neuralgia of the fifth pair gelseminum, either with or without aconite, would effect a cure, or at least give considerable relief. If the pain were due to congestion or inflammation of the pulp or periosteum, he would prescribe also chloride of ammonium. Whilst in chronic periostitis, with suppuration the sulphide of calcium gave results which were in the highest degree satisfactory, cutting short the attacks in the most remarkable manner.

He was of opinion that dental surgeons did not generally give sufficient attention to the constitutional treatment of the cases under their care.

Mr. S. J. HUTCHINSON thought it was a mistake for dental surgeons to undertake constitutional treatment. If this appeared to be necessary, he should communicate with the patient's ordinary medical attendant, and leave the details of the treatment to him. Any other course would inevitably lead to strained relations between dental and medical practitioners, especially in country places.

After some remarks from Messrs. Coleman, Oakley Coles, Gaddes, and others,

The PRESIDENT said it was difficult to define the exact border-line between medical and dental practice, but he thought that, so long as there was any prospect of saving a tooth, the dental surgeon was justified in using any means at his disposal, whether constitutional or local, with this object. At all events, he thought that every dental practitioner ought to have a thorough knowledge of the value of constitutional remedies in dental practice, and in order to promote this he should be glad to see a chair of pharmacology attached to every dental school.

“SALUS POPULI SUPREMA LEX.

WEDNESDAY, MAY 4, 1881.

HOW NOT TO DO IT.

WE tender our hearty congratulations to the members of the General Medical Council on the brilliant success attending their most recent exhibition of inefficiency. We can imagine them retiring to the seclusion of their own homes, in the firm conviction that they have maintained

the reputation they enjoy for blundering inconsistency; and we feel no hesitation in assuring the Council that after sitting through the five weary days during which its debates were held, our sense of its feebleness is more than ever strong. On former occasions we have been edified, in common with the rest of the world, by observing how very ridiculously an assembly of fairly intellectual men could behave, but never before have the proceedings of the Council been so absolutely purposeless or nonsensical as those characteristic of the session just concluded. Why the Council was summoned at this time is still an unexplained mystery. It is true the President made a rambling allusion to it, both in his opening address, and when Mr. Macnamara's motion for a stated annual meeting was under discussion; but it was impossible to gather from either reference that any stronger reason than that a Royal Commission has been appointed which might be inclined to demand some evidence of work from the General Medical Council. With a strange and regrettable fatality, the few sensible proposals that from time to time find their way on to the Notice paper of the Medical Council, are forthwith scouted by a majority, which seemingly finds its only pleasure in aimless demolition and reconstruction. Last year Mr. Simon struggled bravely to provoke discussion on a point of vital interest, and of the first importance to the medical profession; but the attempt was burked ere it could prevail against the indignation invariably aroused in the Council when anything approaching to a sensible suggestion is made before it. This year again, Mr. Macnamara moved that the Council should meet each year at a stated time, and the reasonableness of this proposition will be at once apparent to anyone not blinded by the prejudice that is strongest where penetrative power is weakest. Needless to say, perhaps, the Council rejected Mr. Macnamara's proposal in a manner that seems to be a favourite one with it; that is, moral suasion being brought to bear on him, the mover “withdrew” the obnoxious resolution. We may very well rest content with this ending to the scene, since it will help to point the necessity for a radical change in the existing machinery of the Council, a change of which that body itself apparently indicates a prescient sense, if we may judge from its President's apologetic utterances, several times repeated, as to a desire to reduce the expenses of conducting the affairs that engage its attention. That the general profession will much longer consent to be paymaster, for the purpose of enabling a couple of dozen gentlemen to meet together at more or less frequent intervals, and do nothing in the way of legislation for medicine, save such performances as have disgraced the last few sessions of their proceedings, is impossible to expect. Year by year surely, and, by no means, slowly, the General Medical Council has separated itself farther and farther from the sympathy of practical followers of medicine; widespread as the feeling of dissatisfaction is however, it is by no means so universal as it would surely be, could the rank and file of medical men but once be present at the assemblies of the medical Parliament. To their honour and credit, be it said, a few members of the body are conscious of the appearance it presents in consequence of its illogical and undignified performances; and in the discussions on

one important subject, the registration of additional qualifications on the Dentists Register, there were found five gentlemen who declined to follow the lead of Dr. Storrar in self-stultification. This point had already been definitely settled, as is well known, and the admission of the additional titles on the Register had been, and was again, before the vote was taken on Thursday last, declared to be illegal. How, in the face of this expression of opinion from the Council's legal adviser, it was decided by 13 against 5, to so admit these titles will be found in our report of that day's proceedings. Dr. Quain, as the leader of the minority, will have the satisfaction of knowing that his strong common sense, though it fails to preserve the reputation of the Council, is, nevertheless, admitted outside of its chamber.

An earnest attempt to render yet more complicated the arrangements connected with preliminary education only partially succeeded, but it proceeded so far that no one but a sphinx can, at the present moment, decide what is, and what is not, a registrable proof of previous education. It is true that Mr. Macnamara, on Saturday, strove to excite the energies of the Council to the point of, at any rate, *beginning* to do something, by proposing to consider the replies relating to preliminary scientific education. Unfortunately, however, he once more permitted his good sense to be overruled, the plea for inaction being that five days had already been consumed, and it was inadvisable to strain the powers of the Council farther. The argument was a fair one, no doubt. The repose of Sunday might have conduced to a changed view of their duties and pledges, on the part of councillors, and the result *might* have been that Monday's sitting would result in the achievement of something over and above meaningless talk. Fortunately—we say it of strict intention—fortunately, this endeavour failed, as of late, has every effort by an independent member to do anything in the shape of solid work at the Council. This is generally recognised and admitted, and also that the condition of medical education becomes each year more hopelessly entangled amid the never ending contradictory “recommendations” of the Council. It seems to be an axiom that this august body shall be each year sublimely ignorant of its past decisions, and enact afresh at each sitting, rules and regulations bearing on the same points of consideration. The consequence is that the medical student knows never what he may not be required to alter in the future, what to enter on, or how to act in view of the changes certain to be “recommended” as the result of each thousand pounds expenditure by the Council. To all this there can only be one end, and that, the thorough reconstitution of the Council. With all respect it must be said that the few members of it who really know the claims and requirements of medical education, are very few indeed; and the matter is one of no great wonder either, for, since the majority of the present members were students of medicine, the whole face of medical education has undergone a revolution, and their sympathy is with the past. They are interesting as relics of the past, but as helping to form the future they are of no use at all. The very few, represented chiefly by Mr. Simon, Dr. Quain, and Prof. Humphry, have observed

the signs of the times, and gauged the meaning of them. The Council of the future will be made up of men having like appreciations, and as considerable power of weighing the needs that exist; but ere this occurs it will undergo very material alterations.

#### IMMATURE ENLISTMENT AND SHORT SERVICE IN RELATION TO PUBLIC HEALTH.

THE system under which the British army is supplied with material involves, in the first instance, the enlistment of immature lads; in the second, their discharge from its ranks, back to civil life, at a time when they have acquired the maturity of manhood, when they have become most fitted for and efficient in the performance of military duty, but too old and too unsettled to steady down to the drudgery of learning a trade. Another class, far from inconsiderable in number, return to civil life, their health impaired by service in trying climates. Of these, a considerable proportion have been in the ranks for periods less than those for which they were originally engaged; and are, moreover, in the unfortunate position that they are physically incapable of earning a livelihood for themselves. Circumstances of recent occurrence have drawn public attention to the purely military aspect of this question: the verdict one of most definite condemnation. Financially, it has fully verified the commercial principle that a commodity, bad in itself, is dear at any price; in its purely medical aspect it presents results that have been well described as hideous and hateful, wasteful and extravagant.

Nowhere are the results of this system so apparent as in India—for this reason: that the larger portion of our army serves there. Let us, then, consider the question more especially in relation to that portion of our empire. The result of statistics carefully prepared while the system of long service in India was in full operation was that mortality was greatest in the early years of residence, that after about the third year it decrease very materially till about the eighth or tenth, after which it again rose; that, on the other hand, invaliding *was* inconsiderable up to the fifth year of Indian service, but from that time rose with an annual increase. Similar statistics with reference to dates more recent indicate that the ratio of deaths among the first and second of the above-named classes has diminished; but the rule, as just stated, holds good with regard to all the others. The fact, however, is well known to and by medical officers in India that of late years newly-arrived soldiers are sent to hill stations in much larger numbers and proportions than was the case in former years; that their residence at those places extends to one and sometimes two entire years, during which they are removed from the causes which produce illness and death among the older and physically stronger men who perform regimental work in the plains. Thus, although saved from swelling the bills of mortality, they are, meantime, to all intents and purposes, non-effective, their duties thrown upon their comrades at regimental head-quarters, to increase thereby the wear and tear to which the latter thus become exposed.

Taking the statistics of deaths and invaliding among

British troops, and for the sake of convenience confining observations to those of Bengal, we examine the results obtained at three different periods. The first of these includes the years 1862, 1863, and 1864—namely, a time prior to the full development of "scientific" sanitation, and before the introduction of short service in addition to immature enlistment. The average for these three years gives a death-rate per 1,000 of 23.49; invaliding, 31.70; equal to a loss by sickness of 55.19 per annum.

The second period embraces three years, at an interval of ten years from the first, when, for a considerable time, "scientific" sanitation had been in full swing, at an enormous expense to the Indian Government, and when the influence of short service was beginning to be felt. For the years in question, namely, 1872-3, the results give an average annual ratio of loss by death of 16.06, as against 23.49; of invaliding, 38.78, as against 31.70; total loss by two causes of 57.84, as against 54.87. In other words, in the latter period, as compared with the former, a decrease in the death-rate is found equal to 4.33 per 1,000, but an increase in invaliding equal to 7.08, the whole showing an increase of non-efficiency with the preceding equal to 2.77 per 1,000. Great changes in several of the conditions of the soldier in India had taken place during these ten years. An increase had occurred in the number of recruits sent to the country; the magnificent barracks, planned in 1865, extended over the three presidencies at an expense of many millions of rupees to the Indian tax-payer; hill stations multiplied threefold, their sites cleared, all necessary buildings erected for the purpose of health, and great comfort of the young lads now being sent to them; large and costly troopships had been instituted by sea; railways multiplied by land, so that unless a soldier happened to succumb rapidly to an attack of sickness, he was sent away from the locality where he became ill, either to a hill sanatorium, or to England, as the case might be. In this way, and at such cost, statistics showed a diminished death-rate; actual conditions a very notable increase in non-efficiency in the ranks, and a heavier drain upon the Indian exchequer.

Come we now to the three latest years, returns for which are complete, namely, 1876-7-8, and these are the results obtained, namely, a general annual ratio of deaths equal to 16.50, of invaliding, 39.10, or a total rate of non-efficiency by these causes equal to 55.60 per 1,000. It is worth while to dwell for a little upon these figures. Comparing them with the first period here alluded to, they show a decrease in the death-rate equal to 6.99 per 1,000; but an increase in that of invaliding, equal to 7.40; the total loss, 55.60 per annum, as against 55.19 before "sanitation," according to so-called "scientific" principles had begun, but also before short service was introduced, and before the Budget estimates on account of the army in India had run up from eleven millions to seventeen millions sterling.

Is the question asked, what becomes of the men thus invalided from India, and from other foreign stations after they arrive in England? The minority, perhaps, return, after a time, to military employment for a few months, but seldom, indeed, does a man, sent home once, in consequence of disease contracted in the tropics, become fit for service in a climate of that nature again. Thus the

greater number of such men revert to civil life, but with circumstances adverse to them in several respects; with health impaired, without employment or means of livelihood; occupations with which they were employed previous to enlistment now filled up by other "hands." Is it, therefore, to be wondered at if privation and want in very many instances, press such men downwards to the classes who fill our hospitals, poor-houses, and jails. And so, year after year, increasing in magnitude, these two streams run on; the one into the army, composed of selected young lives, withdrawn from the growing manhood of our country, the other, of damaged lives returned to the stratum from which our soldiers, artisans and labourers, are chiefly taken. Perhaps the influence of these conditions upon the physique of that stratum is not very apparent if looked at only with reference to a very short period. When, however, it is taken into account over a series of years, and considered in connection with other conditions, the tendency of which is also to influence public health, the conviction strengthens that the system by which short service in the active army is united to that of immature enlistment, is disadvantageous and objectionable to the interests of the community at large, alike in the sense of its military and financial interests, and as regards its physical standard.

OUR COMING GENERATION.

THE annual list of the medical students who were registered in the year 1880, has just been issued by the General Medical Council, and it contains some interesting and instructive figures.

The total numbers for the three kingdoms are as follows:—

England	...	...	...	..	983
Scotland	...	...	...	...	589
Ireland	...	...	...	...	534
Total	...	...	...	...	2,106

From this it might be taken that England educates a little less than half (48.6 per cent.) of the entire number of students; Scotland a little more than a quarter (27.6 per cent.); and Ireland a little less than a quarter (23.8 per cent.); but these figures must be taken *cum grano salis*, inasmuch as registration of students which is universal in England has been greatly neglected, and even intentionally evaded in Ireland. In that country certain schools have been glad to catch the fees for entries for courses of lectures long after those courses had commenced; even in February and March when they were nearly terminated. As this practice was totally at variance with the orders of the General Medical Council, these schools were afraid to let the dates of entry be known, and they did their best, with great success, to prevent students from registering themselves, because, by doing so, a date of commencement of study should be stated, and it was not always convenient to state such date. This system the Irish Branch Medical Council tolerated, and consequently the registrations were few. The proof that this trick was habitually played will be found in the table appended to this Register, which shows that ten years ago the registrations in Ireland were only one-half as numerous as those in 1880, a fact which

attributable not to a recent increase in the number of students, but to greater stringency with regard to registration, and more honesty in school management. Even now the registration is not reliable, and, therefore, the relative figures given above cannot be depended on as a truthful index of the respective shares taken by England, Ireland, and Scotland, in educating the profession.

Of the 983 medical students educated in England, about one-half (450) commence study in the following London hospitals :—

St. Bartholomew's ...	100	Charing Cross ...	27
Guy's ...	71	Middlesex ...	25
University College ...	57	St. Mary's ...	14
London Hospital ...	46	Westminster... ..	13
King's College ...	40	School for Women ...	8
St. Thomas's... ..	39	Other Hospitals ...	4
St. George's ...	36		

A little more than half (503) the English students commenced their education in the provinces, of whom over one-third (188) began as pupils to medical practitioners. It is a serious question how far this latter class of students will receive any useful instruction during their first year of study? for it may reasonably be suspected that the certificate of a general practitioner is not always to be depended on, and as the *soi disant* pupil is not examined at the end of his year, there is no other guarantee save this certificate that he has not been simply idling for his first year. We imagine that the four years of study of these students sometimes means three years, and the payment of a fee to the general practitioner. The remaining two-thirds of the provincial students entered at the local schools and hospitals in the following relative proportions :—

Cambridge ... ..	66	Bristol ... ..	19
Owens College ... ..	51	Sheffield ... ..	13
Liverpool ... ..	31	Birmingham... ..	10
Durham ... ..	29	Other provincial hospi-	
Leeds ... ..	27	tals ... ..	68

To which should be added, with a separate line for itself—

The University of Oxford and Regius  
Professor Acland ... .. 2!!!

The Scotch schools are few in number, but great in medical work. In the whole of Scotland only one student registered as a pupil to a general practitioner. All the others, to the number of 588, were entered for study at one or other of the following six schools :—

Edinboro' University	277	Edinboro' Extra Aca-	
Glasgow University ...	135	demic teachers ...	20
Aberdeen University	80	Glasgow Royal Infir-	
Anderson's University	29	mary ... ..	5

We reserve reference to the Irish schools as the figures relating to them seem to need further verification.

## Notes on Current Topics.

### St. John's Hospital v. Hoggan.

THE long-pending libel suit brought against Dr. Hoggan and this Journal by the St. John's Hospital for Skin Diseases, Leicester Square, was settled on Monday in the Court of Queen's Bench, in the most unsatisfactory manner. After spending several hours in examinations and cross-examinations, having but an indirect bearing on

the points at issue, the opposing counsel effected a compromise, which gave Dr. Hoggan a verdict of not guilty, whilst the legal advisers on his behalf withdrew all imputations against the management of the hospital. The case against the *Medical Press and Circular* was not proceeded with.

### The Irish College of Physicians on Medical Coroners.

IT is stated that the Parliamentary Committee of the King and Queen's College of Physicians, to whom Mr. Healy's Coroner's (Ireland) Bill was remitted for consideration, has reported to the College that medical men ought to be excluded from coronerships. Not having before us the reasons for this eccentric opinion, we cannot judge of their force, nor can we say that those reasons would not convert us if we only knew them; but we certainly expect that the College at large will reject imperatively such a recommendation unless some overwhelmingly conclusive justification is shown for its adoption.

As far as the profession is at present enlightened on the subject it is decidedly of opinion that upon public grounds alone, and having regard to the nature of the inquiries in which the coroner is to adjudicate, an educated medical practitioner is obviously better fitted for the office than anyone else could be, and supposing he were not as well suited for the duty, we venture to submit that it would not be for a committee of a college of physicians to be first to announce his incompetency.

Probably this new departure is a further effervescence of that new-born magnanimity of mind and glorious disinterestedness which has led certain sanitarians in Dublin to seek to burthen their brother physicians with the obnoxious and unremunerative function of notifying infectious diseases to the Corporation. If so, we imagine they will experience considerable difficulty in carrying their highly philanthropic designs into effect.

### Visitation of Examination.

ALMOST the only piece of valuable work done by the Council during its five days' sitting, in addition to striking off the register a practitioner guilty of infamous conduct in a professional sense, has been the approval of an Examination Visitation Committee. The members of this, too, have been chosen with a greater amount of wisdom than could have been anticipated from an assembly that habitually undoes at one meeting what it has affirmed at a preceding one; and the circumstance will be received as a token that the work done by them will be at least thorough, conscientious, and reliable. The committee consists of three members, only one of whom, Mr. T. Pridgin Teale, of Leeds, is on the General Medical Council. The others are Prof. Gairdner, and Prof. Stokes, of Dublin. The visitations, so long discontinued, did undoubtedly do some considerable amount of good; and, although the work now undertaken must be a lengthy and laborious one, we may safely look for good results from it. The examinations first to be inspected are those of the College of Surgeons in England, Ireland, and Scotland, and the Apothecaries' Societies of London and Dublin.

Mr. Teale and Prof. Stokes were present on two or three occasions last week at the Royal College of Surgeons

of England, at the time during which the primary examination was in progress.

#### Royal Commission on the Medical Acts.

THE Royal Commission to inquire into the operation of the Medical Acts has been at last nominated by the Government, and is to consist of the following members:—the Earl of Camperdown (chairman), the Bishop of Peterborough, Sir George Jessel, Mr. Solater Booth, Mr. W. Cohen, Prof. Bryce, Sir Wm. Jenner, Prof. Huxley, Mr. Simon, Prof. Turner, and Dr. R. MacDonnell. It will be seen that there is a good deal of intellect on the assembly, but not much medicine. Whether the four professional members of it will be able to digest the voluminous improvements likely to be suggested by a coalition between high orthodoxy, law, and biology, will remain to be seen. Before the august assembly commences its sitting, however, the public might feel better satisfied if it were officially assured that in case a commission were appointed to investigate the direction in which improvements in the practice of law are possible, it would be deemed to be satisfactory if composed of a doctor, two professors of poetry, a novelist, three divines of varying "doxies," an actor, and four lawyers. We do not, of course, suppose for a moment, that the non-medical members of the new commission will not be quite competent to weigh every point brought to its consideration; the Government, with its unparalleled capacity for avoiding every kind of blunder, will have taken strict precaution against any possible failure or breakdown during the commission's sittings. We welcome the appointment, and, with hope rather than trust, await the advent of reform in the profession of medicine.

#### The Price of Martyrdom.

THE martyrs of this age enjoy advantages which those of a remotely earlier period were denied. For instance, the average martyr of the nineteenth century is privileged to compound the consequences of his performances by the prosaic "five shillings and costs;" and very possibly the enjoyment he experiences, though less momentarily acute, is as considerable as that of the martyr who paid as the price of publicity a hand, or an arm, or even life. At this period of the world's advance, martyrdom is rather at a discount, and this is possibly a full explanation of the fact that its consequences are monopolised by a sect—the anti-vaccinators. The amiable weakness which leads these mischievous promulgators of the doctrine of diseases, is attended by the slight personal evils that cling about a fine, it is true, but it does inestimable damage by publishing the fact, that notoriety may be thus cheaply purchased. We are glad, therefore, to note that a person named Goble—it sounds like an anti-vaccinator's name—has been fined £25 by the Recorder of Brighton for an assault on Dr. J. H. Ross, a public vaccinator, whilst engaged in the performance of his duty. This kind of martyrdom may be found a trifle too expensive by the band who usually buy it with an outlay of two pounds and two shillings costs, and at the same time leave their unfortunate offspring to regret its parents' craving after ephemeral fame. To this kind of ambition we have less objection, perhaps, but when the enthusiasm ends in personal attacks on the ob-

noxious servant of science and common sense, it is widely different; and we trust any future martyrs of the same description may be as heavily punished.

#### Pensions for the Indian and Army Medical Service.

THE Secretary of State for India in Council has approved of the following revised scale of Pensions for the Indian Medical Service, to have effect from Jan. 1, 1881:

After seventeen years' service, including 1 and 2-3rd years' leave on furlough, £292.

After twenty years' service, including two years' leave and furlough, £365.

After twenty-five years' service, including three years' leave and furlough, £500.

After thirty years' service, including four years' leave and furlough, £700.

With extra pension, £350 and £250 per annum respectively, to surgeon-general and deputy surgeon-general on completion of tour of appointment.

Let us compare these scales with the rates of half-pay granted to officers of the Army Medical Department, and these are the results we find: In the latter an officer, after seventeen years' service, is entitled to no pension whatever, but only to a gratuity of £2,500, which, if invested in consols, would yield him as income the munificent sum of £75 per annum. After twenty years' service, if a surgeon-major, he receives as pension £365. If a brigade-surgeon, as in nine cases out of ten he will be, £500. After twenty-five years he receives, if a surgeon-major, £405. No increase as brigade-surgeon. After thirty years' service, £456 if a surgeon-major; £547 10s. if a brigade-surgeon, as against the £700 granted by the Indian Government. In the Army Medical Department the rates of retired pay are: for a deputy surgeon-general, £630 per annum; for a surgeon-general, £730, in both cases after twenty years' service, and without increase either for length of time in these ranks respectively, or in the service. In the Indian Medical Service, provided an officer has held the *appointments* respectively for five years, he receives as pension, if a deputy surgeon-general, £222 per annum more than in the British Service; if a surgeon-general, £320 more. These figures speak for themselves very unmistakably to intending candidates.

#### Mr. Charles Darwin on Vivisection.

MR. DARWIN has been so long known as a humane man, and had identified himself so warmly on a former occasion with a Bill to control experiments on living animals, that the anti-vivisectionists counted him and paraded him as a sympathiser with their political vagaries and ignorant misrepresentations. To put a stop to the use of his name in this way, Mr. Darwin has written a note to Professor Holmgren, from which we select the following passage:—"I know that physiology cannot possibly progress except by means of experiments on living animals, and I feel the deepest conviction that he who retards the progress of physiology commits a crime against mankind. Anyone who remembers, as I can, the state of this science half a century ago, must admit that it has made immense progress, and it is now progressing at an ever-increasing rate. What improvements in medical

practice may be directly attributed to physiological research, is a question which can be properly discussed only by those physiologists and medical practitioners who have studied the history of their subjects ; but, as far as I can learn, the benefits are already very great. However this may be, no one, unless he is grossly ignorant of what science has done for mankind, can entertain any doubt of the incalculable benefits which will hereafter be derived from physiology, not only by man, but by the lower animals."

#### Vaccination and Small-pox.

A SMALL pamphlet, prepared by the National Health Society, revised by, and issued with the sanction of, the Local Government Board, draws attention to the prophylactic power of re-vaccination against small-pox, and contains full directions as to how, without cost, persons may be vaccinated. Twenty thousand copies of this pamphlet have been circulated during the past few days in the Poplar Union, and large numbers have been sent to all the Metropolitan boards of guardians, with a similar object ; it is thus hoped that, by its extensive circulation this pamphlet may neutralise some of the pernicious literature adverse to vaccination that is being somewhat zealously distributed. It briefly indicates that the only protection of any avail against small-pox is vaccination, which not only modifies very greatly the severity of an attack, but in the great majority of cases wards off an attack altogether. It points out with regard to the alleged injury from vaccination that, with due care in the performance of the operation, no risk of any injurious effects from it need be feared ; that before its discovery the mortality from small-pox was forty times greater than it is now ; that since vaccination has become compulsory in England the death-rate from small-pox has further diminished to one-half of what it was in the previous sixteen years ; that people who are properly vaccinated escape attack to an immensely larger extent than unvaccinated people ; that in the London Small-Pox Hospital, whereas the rate of mortality by that disease was under one per cent. of thoroughly vaccinated persons, it exceeded 35 among those who were unvaccinated ; and that the degree of protection against small-pox is in direct proportion to the thoroughness of the vaccination. The facts thus brought together cannot be too much insisted upon, particularly at a time like the present, when small-pox has spread in the metropolis to an unusually great extent, and appears to be still on the increase.

#### Remote Sequela of Tracheotomy.

At a recent meeting of the Académie de Médecine, a note was presented by Dr. Mougest, of Troyes, to the effect that children who have undergone tracheotomy rarely, if ever, attain their majority. At Paris there have never been found conscripts with traces of tracheal cicatrix. This should not lead us to discourage tracheotomy, but to modify the method of operating. The disuse of metallic canulæ as advised by Dr. Martin, of Boston, would have the effect of preventing the production of the pulmonary emphysema and laryngeal phthisis which so often follow tracheotomy.

#### Domestic Life in the Transvaal.

FROM an interesting account of the Boers recently published, we learn the following particulars in regard to the habits of that people in so far as they relate to principles of hygiene and sanitation. The Boers rise at daylight ; they are indolent and dirty in their habits ; their drink consists of café noir ; they smoke tobacco almost continually throughout the day ; their diet is without variety, they make use of scarcely any vegetables ; personal cleanliness is unknown amongst them, their toilet consisting solely of a basin of water and a towel, no soap, sponges, hair brushes and tooth brushes, quite unknown to them ; their toilet prepared on the table the meals are taken at ; their appearance most dirty, uncouth, and unkempt. Their wives fat, badly and slovenly dressed, without stockings ; children, rosy-cheeked, dirty, ill-dressed, and ill cared for. Fowls, &c., run loose about the house. Here then is a state of things so completely opposed to all recognised principles of hygiene as can well be, and with what results upon the physique of the people ? The men are healthy, strong, hardy, courageous, capable of undergoing almost any extent of fatigue and exposure. Can more be said of results which have followed the application of scientific sanitation in its highest development ? In fact, do not these details suggest their own commentary ?

#### Health of Dublin.

THE average annual death-rate for the week ending April 23, 1881, in the sixteen principal town districts of Ireland was 28.9. The mortality, last week, in 20 large English towns, including London (in which the rate was 22.5) was equal to an average annual death-rate of 22.0 ; in Glasgow the rate was 22.9, and in Edinburgh 22.3. In the Dublin District, the deaths represent an annual rate of mortality of 32.4. Only 15 deaths from zymotic disease were registered, being 1 less than the number in the previous week, and 23 under the average for the sixteenth week of the last ten years. Twenty-five new cases of typhus were admitted into the principal hospitals during the week, being 11 under the admissions for the preceding week, 13 typhus patients were discharged ; 2 died ; and 103 remained under treatment on Saturday last, being 10 over the number in hospital at the close of the previous week. Two cases of typhoid fever and 6 of scarlatina were admitted against 6 and 7 cases respectively in the preceding week.

#### Atropine in Acute Middle Ear Inflammation.

BASING his observations on the good effect produced by atropine in eye affections, Dr. Theobald has used this remedy in aural diseases, and is convinced of its value. He has found it useful in cases of inflammation of the external meatus ; he has however seen its most active effect in acute inflammations of the middle ear accompanied by violent pain especially in children, also in cases of severe otitis media supervening on febrile exanthemata. Dr. Theobald instils into the ear 8 or 10 drops of an aqueous solution (4 grms. to the ounce) and leaves it there from 10 to 15 minutes. The instillation may be repeated every three or four hours, according to circumstances. When the membrane was intact he never saw any general effect produced ; in one case

when the membrane was perforated and when the remedy had been frequently employed on both sides, there appeared dilatation of the pupils in a little girl, 3 or 4 years old. The author however is undecided whether in this case the atropine was not carried directly to the eye by the finger. Dr. Theobald has seen the value of atropine in the case of his own child.

### The Notification of Infectious Diseases in Dublin.

THE Executive Committee of the Dublin Sanitary Association met last week and adopted the following resolutions:—

“That, in the opinion of this committee, any bill to provide for the notification of infectious diseases in Ireland should be compulsory, and should apply to every sanitary district in Ireland. That the medical practitioner (if any) in attendance shall either note directly to the sanitary authority the existence of a case of infectious disease, or else hand a notification to the occupier of house or person in charge of inmate.” “That a fee shall be payable only in case of the medical practitioner reporting directly to the sanitary authority. That where no medical practitioner is in regular attendance on a person suspected to be suffering from an infectious disease within the meaning of this Act it shall be incumbent on the occupier, &c., to obtain a certificate from a registered medical practitioner as to the nature of the disease (if any), and in cases where the sick person is entitled to gratuitous medical attendance, said occupier shall obtain such a certificate from the medical officer of health of the district in which the sick person resides.”

There is nothing unexpected in an Association of professed sanitarians deciding to sacrifice the medical profession on the altar of the deity at whose shrine they worship, but it was with much surprise that, on examining the list of members present when these resolutions were voted, we found that six out of eleven were medical men. Desiring further light on the subject, we addressed to the Association an official request for information as to the numbers for and against these resolutions, and received a polite refusal. We are, however, able to supply the information which was officially denied us, and to state that the two resolutions to force upon the physician the duty of notifying and to refuse him any fee for doing so unless he sends his report direct to the sanitary authority were each carried by a majority of *one*, the voting being five to four.

We do not imagine that the champions of notification will derive much encouragement from a verdict in their favour delivered by a bare majority in an assembly of eleven persons, and we anticipate that the medical profession will warmly resent the declaration of the Dublin Sanitary Association that, unless the physician pleases to post or carry his notice to the city hall or to the clerk of union he shall be paid nothing for his trouble. Even Mr. Gray's generous offer of a shilling for thirty days' notification is better than the tender for doctor's services made by five-ninths of the committee of the Dublin Sanitary Association.

Meanwhile, we are glad to say that the opposition to the measure by the medical profession in Ireland is being vigorously pursued. The whole case against the Bill has been put before the public by Dr. Jacob in a letter to the Dublin papers, which elicited a reply from Mr. Gray, and a further replication from Dr. Jacob, who hastened to

point out that not one professional organisation had approved of the Bill, and that the verdict of the profession—so far as it had been delivered—had been one of unqualified condemnation. This correspondence was followed up by a resolution against Mr. Gray's method of notification, adopted by the North of Ireland Branch of the British Medical Association. The Irish Medical Association has been active in preparation for the parliamentary campaign against the Bill, and has drawn amendments the effect of which would be to throw the onus of notification on the house occupier, or the custodian of the patient, which amendments it has asked Mr. Gray to accept, but his reply has not yet been received. A deputation from the Executive Committee of the Association also waited, on Saturday week, by appointment, on Dr. Lyons, M.P., to submit the views of the Association, and the proposed amendments, the purport of which Dr. Lyons, after careful consideration and inquiry, expressed himself as ready to support. The Association has also prepared a series of explanatory “Observations” on the Bill, for the information of members of Parliament, and the local influence of medical practitioners throughout the provinces is being exercised upon Irish members to cause the measure to be amended. Our readers will thus see that the representatives of medical opinion in Ireland are alive and busy in protection of professional interests in this matter.

### Crawford v. the British Medical Journal.

It is rumoured in legal circles in Dublin that the great Cork pilocarpine case is once more about to occupy the attention of a jury. The medical aspect of the matter was conclusively settled by the action taken by the Cork jury at the late trial after having heard medical evidence. The technical question of “fair comment” upon which the Cork jury disagreed is the one which is now likely to be re-opened.

DR. ALFRED MEADOWS has been selected to deliver the Harveian Lectures this year, the subject of which will be “Menstruation and its Derangements.”

HER MAJESTY THE QUEEN has been pleased to appoint Mr. John Evans, of the well known firm of Evans and Sons, of Dawson Street, Dublin, to be Chemist to Her Majesty in Ireland.

In the principal foreign cities, the rates of mortality according to the most recent weekly returns, were:—Calcutta 27, Bombay 34, Madras 46; Geneva, 25; Amsterdam 23, Rotterdam 25; The Hague 25; Copenhagen 27, Stockholm 34, Christiania 15; St. Petersburg 63; Berlin 25, Hamburg 23, Dresden 28, Breslau 34, Munich 32; Vienna 34; Buda-Pesth 37; Rome 32; Turin 30, Venice 25; Alexandria 32; Brooklyn, 23, Philadelphia, 22, Baltimore, 25, per 1,000 of the population.

THE general fatality of measles, scarlet fever, and whooping-cough in the large towns last week was considerably below the average for the season. The 27 deaths referred to diphtheria included 10 in London, 7 in Portsmouth, 3 in Edinburgh, 2 in Glasgow, and 2 in

Plymouth. The highest death-rates from fever were recorded in Glasgow, Portsmouth, and Bristol. Small-pox caused 88 more deaths in London and its outer ring of suburban districts, 1 in Liverpool, and not one in any of the other large towns.

## Scotland.

(FROM OUR NORTHERN CORRESPONDENT.)

THE LATE LORD BEACONSFIELD.—An immense amount of snobbish writing has been indulged in over the fatal illness of this eminent statesman. There is no *rolé* among the many contemptible *rolés*, we regret to say, with which some medical practitioners may be charged, more contemptible than that of the individual who assumes transcendent knowledge after the event. Do we not all know the doctor who expresses regret at his having been called so late, that other measures had not been employed, and more than hints that a fatal termination might have been averted? We say this is a despicable part to play; it leaves painful, however groundless, regret in the hearts of many, while the coward who resorts to it, protects his affected superiority behind a position in its nature absolutely incapable of proof or denial. One of the leading medical journals, in alluding to the medical aspects of the illness of Lord Beaconsfield, remarks, "From the outset of the last illness the case was, in our judgment, hopeless, unless the higher cerebral centres of the nervous system came to the relief of the lower." We are tempted to ask, has this jargon any meaning? Would it not be as philosophical to say, "unless Providence came to the assistance of the lower nervous centres, Lord Beaconsfield must die." Is this pseudo-metaphysical science one whit better than the inflated bathos of the homœopaths? Is it not a great deal worse as coming from a journal which affects to lead scientific and lay medical orthodoxy? With a view evidently of "stimulating the higher centres," the same authority states, "It must ever be a source of regret that Lord Rowton . . . was unavoidably absent during the first and only hopeful stage of his (Beaconsfield's) illness. . . . also, we think, unfortunate that Lord Rowton did not see the noble lord until four days after his return. . . . also that Her Majesty's graciously expressed desire to visit the noble lord was not carried into effect." If Her Most Gracious Majesty and Lord Rowton possess thus the faculty of stimulating the higher centres in order that they may come "to the relief of the lower," and thus save dying statesmen from the "King of Terrors," the *rolé* of the Bambino is one which, so far as we know, has not yet been fairly tested in these realms.

A SURGEON'S JUBILEE.—A very worthy practitioner of medicine—Dr. John Borland, of Kilmarnock—was entertained to a supper, in the George Hotel, of that town, on the 29th ult., and presented with a testimonial consisting of a purse containing 500 sovereigns, together with a silver salver and gold brooch for Mrs. Borland, on the occasion of his jubilee as a medical practitioner in Kilmarnock. There was a large and influential company, including many medical men from a distance. The duties of the chair were discharged by Provost Sturrock, and those of croupier by Professor H. B. Macleod, Glasgow. Dr. Borland, in the course of his reply to the presentation, delivered an interesting speech, retrospective chiefly of the advances

which he had witnessed in medicine during his lengthened experience, prominent amongst these being vaccination, the use of anaesthetics, the study of hygiene. In surgery he remarked that "hospital diseases" had almost been stamped out, and sagaciously observed that this advance was equally notable in hospitals where the most varied and opposite methods of wound treatment were employed. The salver bears the inscriptions—"Presented to John Borland, M.D., with a cheque for £500, and a gold brooch for Mrs. Borland, on the occasion of his jubilee as a medical practitioner in Kilmarnock, in recognition of the invaluable services rendered to his native town during the past half-century. Kilmarnock, April 29th, 1881."

A HAPPY PEOPLE—DYING WITHOUT DOCTORS.—Mr. Peter White, surgeon, Busta Delting, has published a paper under the title, "Mortality and Medical Attendance in Shetland," in which he points out that about three-fourths of the deaths which occur in the Shetland Islands are not certified as to their cause by any medical man, and urging that, either by Government grant, or private charity, funds should be provided to establish dispensaries in the places most distant from the doctors, and to pay medical men for attending at these dispensaries not less frequently than once a week. Dr. White points out that the death-rate in Shetland is very low, only 13 per 1,000 annually, and justly observes that the cynical will be apt to draw conclusions therefrom, not altogether flattering to the Faculty. He thinks, however, that it is almost inconceivable that amongst the 75 per cent. of rural Shetlanders who die unattended by medical men, there would not be many whose distress would not be much increased by the reflection that they could not procure the aid which is usually so firmly relied upon by the sick and the dying. Ministers, who, it appears, seem to be abnormally abundant in these Islands, are said to possess a considerable knowledge of the healing-art, and to prescribe largely for the sick. As clergymen, of all other classes have, the most pronounced penchant for quackery of all sorts; we hardly regard clerical medication as of much value, indeed, it would be interesting to learn if the death-rate is not much higher in the realms of clerico-medical solicitude.

PROPOSED NEW HOSPITAL FOR GLASGOW.—A meeting of those favourable to the institution of yet another hospital for Glasgow was held in the Religious Institution Rooms, Glasgow, on the 27th ult., the Lord Provost presiding. The chairman said that this movement was in no way antagonistic to existing hospitals. Considering the question whether they had sufficient amount of hospital accommodation in Glasgow, it would, he thought, be admitted that there was a deficiency. As contrasted with Manchester, Dublin, and Liverpool, there was much less hospital accommodation in Glasgow. We have no sympathy with this movement. We do not stop to inquire into the motives of its promoters, or the financial prospects of the contemplated undertaking; but this we fearlessly assert that, when the social aspects of society in the nineteenth century come to be philosophically written, it will doubtless be recorded that much of the crime, the poverty, and the debauchery with which it must be held chargeable will be justly ascribed to the flagrant and wanton pauperising of the lower orders, after the fashion of mandlin philanthropy concealing self-seeking, and the aggrandisement of the few at the expense of the many. This is an argument that needs no enforcing. What are the facts as regards Glasgow? That at least the enormous proportion of one in four must be medically treated gratuitously; that, compared with thirty or forty years ago, there is hardly any working-class ractice whatever; that professional poverty is unquestionably

more ripe, while the number of medical practitioners is much increased; that young men discover, when they begin practice in most of our large centres of population, that they find themselves in competition (not always the most honourable) with the teachers from whom they have just parted company. Of the effect on the public there is no need further to dilate. The *Evening Citizen*, in discussing the prospects of the proposed hospital considers that "the monetary problem is both real and serious," and on this account augurs unfavourably for the institution. It contends that hospitals should not be dependent on the benevolence of the few, but should be supported by a public rate; and it enunciates the astounding proposition that "public healing is surely as notable as public teaching, or public park-maintenance, or public street-cleaning." We demur emphatically to the proposition. "Public healing" is no more a matter for public taxation than public clothing, public drinking, public feeding, or public buying of half-penny "dreadfuls." For what purpose, we would ask, has the parochial system been instituted? We repeat, we have no earthly sympathy with this movement, and will not be guilty of the affectation of saying that we wish it any success whatever.

**HEALTH OF EDINBURGH.**—During the week ending with Saturday, the 23rd ult., 98 deaths occurred in Edinburgh, and the rate of mortality was 22 per 1,000 per annum. Over 80 deaths were due to diseases of the chest. Scarlatina and whooping-cough each proved fatal in 10 cases. The southern suburbs continue to be entirely free from zymotic diseases.

**GLASGOW ROYAL INFIRMARY.**—Mr. Hy. E. Clark has been promoted to the position of Surgeon to the Royal Infirmary, Glasgow, vacant by the transference of Dr. Hector C. Cameron, to the Western Infirmary.

**THE "MILK EPIDEMIC" IN ABERDEEN.**—The Court of Inquiry into the nature of this epidemic has terminated its investigation. A considerable number of local medical men were examined. The report to the Board of Supervision has not yet been made public.

**GLASGOW ROYAL INFIRMARY DISPENSARY.**—For the office of Surgeon to the Dispensary Royal Infirmary, vacant by the promotion of Mr. Clark, we understand that Drs. Foulis and Whitson are candidates.

**ABERDEEN ROYAL INFIRMARY.**—Dr. Edward W. Robertson, of Duftown, has been appointed Assistant House-Physician, and Dr. George Shirres, Assistant House-Surgeon, to the Royal Infirmary, Aberdeen.

**GLASGOW UNIVERSITY.**—The ceremony of capping the new graduates took place at the University of Glasgow, on Friday, the 29th ult. A large company of ladies and gentlemen attended. The degree of LL.D. was conferred on Andrew Buchanan, M.D., Emeritus-Professor of Physiology in the University.

### THE PROPOSED EXAMINATIONS IN THE IRISH COLLEGE OF SURGEONS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Although dissenting in common with several other members of the Council from your statements as to the advantages, educational facilities, and lessened expense of the proposed examination scheme, I would have abstained from notice of them had not two important events since occurred. First—Medical education is to be inquired into by a Royal Commission, the composition of which is a guarantee that the investigation will be thorough and that surgical interests will not be neglected; and second, the

Medical Council has negatived by 14 to 2 the expediency of holding annual examinations which the students should pass before entering on the subsequent year's course. The minority consists of our representative and our President; the majority includes the representatives of seven licensing Corporations and of five Universities, and two Crown nominees. Under these circumstances, the other licensing bodies holding aloof, the sacrifice of our College is not likely to be persevered in, yet it is right that your readers should know there were many who thought the changes inexpedient.

Yours truly,

6 Merrion Square, Dublin.

E. D. MAPOTHER.

[We hope and believe that the vote of the General Medical Council, to which our correspondent refers, will not prevent the Irish College of Surgeons from carrying into effect reforms of education and examination which are necessary as much in the interest of the College itself as for the benefit of the student, and which are not the less deserving of approval because they embody an honest desire to do what is right, *i.e.*, to make the education of the surgeon thorough and practical. We do not regard this vote of the Medical Council as of much influence—Firstly: Because it is the vote of representatives of licensing bodies, of which not one has taken any steps to bring its examinations as regards sub-division of examinations into strict accord with the express recommendations of the Council of which they are members. Secondly: Because most of the votes of the General Medical Council, as is well known, pass unnoticed. Thirdly: Because the Council of the Irish College of Surgeons has contemplated reform and constructed the proposed scheme with a full knowledge that other and larger changes will be, before very long, effected by Act of Parliament, and therefore the relegation of the matter to a Royal Commission is a reason rather for showing the desire of the College for reform than for adjourning the improvements until the indefinitely distant epoch of a new Medical Act. That "the sacrifice of the College," as Dr. Mapother phrases it, is likely to be the result of a reformed system of education and examination, we entirely deny; but we assert that, on the contrary, the proposed scheme will be, and already is (so far as it is known), more popular with the student than the old system, will be cheaper, will be more genuine and yet more easy, and ought to give strength to the College to resist the competition of the new Royal Irish University rather than to "sacrifice" it to the demand of educational improvement in Ireland. No policy would more certainly and effectually "sacrifice the College" than that of maintaining the existing discredited system of repeated courses of lectures, paid for, but not attended; dishonest certificates; credit fee paying; apprentice farming; two years' idling and nine months' work; and all the other abuses which the proposed scheme seeks to abolish for ever.—Ed. M. P. and C.]

## Literature.

### THE BRAIN AND NERVOUS SYSTEM. (a)

1. In his preface Dr. Dowse disavows all intention of entering on vague and speculative theories relative to the pathology of neuralgia, and claims that this work be regarded as a practical treatise in which "curative treatment" is the main point to be elucidated.

The literature of neuralgia is very extensive, but it is scattered through many memoirs and periodicals, and the

(a) 1. "The Brain and Diseases of the Nervous System." Vol. II. Neuralgia: its Nature and Curative Treatment." By Thos. Stretch Dowse, M.D.

2. "On Brain and Nerve Exhaustion. Neurasthenia: Its Nature and Curative Treatment." By Thos. Stretch Dowse, M.D.

attempts have hitherto been few to present the practitioner with a concise handbook on the subject. Our real knowledge of the pathology of this affection is small, while the call for treatment is often very urgent. Therefore we cannot but commend the discretion which the author of the present treatise has shown in confining himself chiefly to the practical bearings of the question.

And practical in the best sense of the word this book is; not consisting of mere "rule of thumb" recipes, but still keeping steadily to the beaten road of that rational empiricism which leads to a truly scientific therapeutics, and a higher co-ordination of knowledge. After a short "Index to Cases," accompanied mostly by a summary of the treatment adopted in each, and very useful for reference, we come to an introductory chapter dealing with the general questions of diagnosis, &c. It is refreshing to find that Dr. Dowse at once shows a bold front to the enemy. "All neuralgias," he says, "are curable if the disease be taken at the right time, and the proper remedies employed, according to the individual constitution and the nerves affected;" but with these qualifications—"If a neuralgia be due to cancer or tumour, or to any other serious organic mischief, then to say that such is curable, would be to say that cancer itself is curable; and in like manner when a neuralgia is due to senile, textural, and vascular changes, the cure is in a measure doubtful, but most certainly not impossible."

Further on we find that our author does not despair of the so-called "epileptiform neuralgia," which has been, since the days of Trousseau, so generally regarded as an *opprobrium medicinae*. "I am not inclined to look so hopelessly upon the incurability of this form of neuralgia as M. Trousseau did, and my experience warrants my making this assertion." Dr. Dowse speaks of "several cases," but, rather unfortunately we think, only gives details of one. In this case the pain came on frequently when the patient tried to eat or drink. Treatment accordingly consisted in feeding the patient by means of a tube passed through the nostrils, giving nourishing and stimulating diet (of course in liquid form), and administering morphia hypodermically. But in how many cases of this most intractable and dreadful affection has morphia failed! Dr. Dowse does not recommend the nasal tube in ordinary cases, nor would any one use it, we apprehend, without some local indication. No doubt its use was of the greatest service in this particular case, and its action was to secure a certain amount of rest.

In the section devoted to treatment generally, due prominence is given to dietetic and hygienic measures. Avoidance of fatigue and overstrain, either of mind or body, is strongly insisted upon. The advantages of alcohol and a nourishing diet, rich in fatty substances, are dwelt on, though the author rightly protests against a routine system of treatment in these particulars. Under mechanical causes of neuralgia, he of course mentions decaying teeth. "One of the most common causes of abdominal neuralgias and sciatica is the distension and impaction of the lower bowel." In this connection it is pointed out that "many a drug which is otherwise inoperative becomes actively operative for the relief of pain after the liver and bowels have been well acted upon." Neuralgia of the womb is often associated with ulceration of the os. Several cases are given of neuralgia of the bladder due to fissure of the rectum, ascariæ, &c.

Electricity is well spoken of. Dr. Dowse finds most beneficial, "first, the continuous current for four or five minutes, followed by faradisation for about the same length of time." He mentions Benedikt's treatment of severe facial neuralgia, namely, passing galvanic currents through the skull, and we are surprised he does not point out the danger which Hammond has shown may attend this procedure. We are sorry to find nerve stretching receive less notice than it deserves. The evidence indeed is not very copious, but it is strong in favour of this operation in otherwise desperate cases. Among the specific remedies discussed are aconite, veratrum, ergotine, gelseminum, strychnia (an invaluable tonic in chlorotic cases), phosphorus, croton chloral, zinc, cannabis indica, &c. Iodide of potassium the author thinks is next to quinine—of the greatest value of all curative remedies in neuralgia. It is most beneficial when we have a clear history of gout or syphilis. Turpentine, recommended by Trousseau in neuralgia of the stomach, is "of first-rate value in ovarian, uterine, sciatic and crural neuralgias," given in the form of enema.

What might be called the "chloral stupe" (a hot solution of chloral hydrate—1 oz. to 16—applied on flannel after the

manner of a turpentine stupe), is certainly a very valuable remedy in many cases, and Dr. Dowse claims the credit of having been the first physician to bring this mode of treatment under the notice of the profession in this country. It is most useful in sciatica. We quite agree with the author in thinking that bromide of potassium is valueless in this affection.

Every practitioner knows the magical effects that often follow from the hypodermic injection of morphia in neuralgia. It is perhaps most beneficial when combined with atropine, but even when thus guarded we must say we consider half a grain a most heroic, not to say hazardous, dose to commence with. We have seen fatal results follow from the administration of half a grain of morphia to a person unaccustomed to the drug. Hammond more judiciously states that 1-6 grain is sufficient for a first injection.

We cordially endorse the rule, "never to continue injections of morphia for more than ten or twelve days" in simple neuralgia, and we think the following advice is also worthy of all praise: "In acute neuralgias, I do not care where they are, you must push a remedy to its fullest extent within 24 or 48 hours, and if it does not answer its purpose by that time, discard it at once; for, depend upon it, it never will, and we must then try another remedy."

We think that, without impairing the practical value of his treatise, our author might have entered more fully upon his reasons for dividing all neuralgias into "ordinary neuralgias, or neuralgias of individual nerves or groups of nerves," and "special neuralgias" (as of the throat, stomach, kidney, &c.). The latter class is very open to suspicion. "Neuralgia of the brain" we look upon as a particularly unhappy term, and the relation of the so-called "nervous headache" to neuralgia is, to say the least, dubious.

Though Dr. Dowse's book contains abundant evidence of mature thought and ripened experience, yet there are traces in it of haste in compilation. Thus it is to be regretted that the special treatment of so important an affection as lumbago should be dismissed in three lines. We cannot praise the manner in which the work has been seen through the press. For instance, all reference to a considerable portion of the text has been omitted from the table of contents. On the whole, however, we can heartily recommend this treatise as a clear and comprehensive text-book for practitioners.

2. Dr. Dowse admits that for many years he discarded the term "neurasthenia," or nerve exhaustion, "for when I was in the midst of pathological work I thought the term vague and unscientific, and I expected the scalpel and the microscope to reveal to me the cause of any arrest of nervous function." In the course of time he changed his mind, and found the term at least very convenient, or, as he says, "in every way most applicable to a number of nervous derangements." It is precisely this general applicability of the name that inclines most people to doubt whether it really expresses any distinct morbid entity. That there is a condition of nervous weakness and irritability such as that to which Dr. Beard has applied the title "neurasthenia" few who see much of nervous diseases will deny, but the questions are—What is it? What does it signify? What are its relations to other nervous affections? Long before Dr. Beard's memoir appeared a similar series of symptoms had been described by various authors as precursors of insanity. Krafft-Ebing, and other German authorities have given good descriptions of what would now be called neurasthenia, occurring in persons of neurotic constitution, whether hereditary or acquired. Dr. Dowse himself says, in the work before us—"I have no hesitation in asserting it to be my firm belief that many of the incurable cases of insanity, locomotor ataxy, progressive muscular atrophy, and many other diseases of the brain and nervous system, commence as a neurasthenia of the nervous centres, and when in this state they are quite amenable to treatment." How far insanity can be warded off must always remain doubtful till we are able definitely to lay our finger upon certain symptoms and say, "These unchecked would surely end in mental aberration;" but the author is undoubtedly right in considering, as we gather from the above passage, that the form of insanity which follows upon the "neurasthenic" state is not hopeful. On the contrary, it is almost invariably of a degenerative type, commonly taking that form which Krafft-Ebing calls "primäre Verrücktheit."

Dr. Dowse differs from Dr. Beard as to the significance of lightning pains. The latter states that they are often associated with simple spinal exhaustion, while the former says:

"Should a patient be suffering from the symptoms of spinal exhaustion, plus lightning-like, plunging and darting pains, although there be no other signs of locomotor ataxy present, let your prognosis be given with the greatest caution, for I feel sure in such cases as these sclerosis of the spinal cord is commencing." The domain of neurasthenia will probably be considerably curtailed as diagnosis of diseases of the nervous system becomes more exact—indeed, we should not be surprised if it follows the ordinary fate of "functional" affections.

Dr. Dowse gives excellent descriptions of the exhaustion produced by overwork in the young, and overwork or worry, or both combined, in the old. The following emphatic sentence is worth note:—"Brain exhaustion from over-study, and so-called cramming the brain is perhaps one of the greatest social evils of modern times, and is simply a blot upon advancing civilisation. It is opposed to all biological laws—social, moral, hygienic, ethical, physical, and rational."

In the section devoted to treatment there is much valuable practical information as to the mode of dealing with nervous depression. Among drugs the first place is given to opium, the watery extract being the preparation recommended. Next comes arsenic, which, contrary to general experience, the author places before phosphorus and strychnia. The salts of bromine, iodine, zinc, and iron, and many other drugs are mentioned, but all routine treatment is deprecated. Cod-liver oil is often of great service, especially for the young. Stimulants are often most beneficial, but require to be ordered with great care, as patients of this class are particularly liable to give way to the temptation to drunkenness. Of the first importance are "rest and nutrition." Under rest is included not merely avoidance of fatigue, which is in itself necessary, but also a removal, where possible, of the cause which may be at the root of the whole affair—for example, some domestic annoyance or business worry, or other more directly somatic cause. No routine can be laid down that will suit all cases. Even the overworked business man's holiday may be overdone or injudiciously done, so that he returns from a tour in search of health more knocked-up than when he went away. In every case we should labour to obtain the confidence of our patient, and never allow him to despair of his condition.

## Obituary.

### DR. THOMAS WILLIS, OF DUBLIN.

This gentleman one of the oldest of the practitioners of a past age has just died at Bray. The patriarchal term in his useful life had extended over 91 years. He remembered the troublous times of '98, and was always a willing and unflinching reference for those who wished to have living evidence of the momentous events of the beginning of the century. It was only recently that the health of Dr. Willis showed signs of failing. His career was one of charity and improving work. As Poor-law Inspector of Bantry, Kanturk, and Cavan, his exertions during the famine are chronicled in the history of that awful period. To Dr. Willis's efforts may be largely attributed the establishment of the society of St. Vincent de Paul, and the Catholic Institution for the Deaf and Dumb, on lines modelled upon those of similar Continental societies. As an author his book on the "Social and Sanitary Condition of the Working Classes" is quoted as an authority. His compilation of rentals known as "The Willis Collection," and purchased for the Landed Estates Court, was a serviceable work, and his library collection is of choice value.

### DR. BERNARD, DUNDRUM, CO. DUBLIN,

On Sunday morning, April 24th, died Dr. Michael Charles Bernard, a much esteemed suburban practitioner and a valued contributor to our pages. Dr. Bernard's entrance into our profession dates as far back as 1834, when he obtained the Bachelorship in Arts and Medicine at the University of Dublin, and the License of the Irish College of Physicians. For nearly forty years he practised at Dundrum, and for most of that time he filled the office of

Medical Officer to the Dispensary, and after his retirement from the Poor-law Service, on pension, he has continued in the enjoyment of considerable private practice in the locality. His contributions to this journal included papers on "A Simple Method of Relieving Retention," on "The Treatment of Bed Sores," on "Punctured Wound of the Elbow," and we hope next week to publish a communication from his pen, on "Reminiscences in Midwifery Practice."

## Medical News.

Royal College of Physicians of London.—The following candidates having passed the required examinations were admitted members on April 28:—

Bradshaw, James Dixon, M.B. Oxford, 29 Hyde Park Place, W.  
Haynes, Frederick Harry, M.D. Lond., Leamington.  
McAlister, Donald, M.B. Camb., Cambridge.  
Meeres, Edward Evan, M.D. Lond., Plymouth.  
Moritz, Siegmund, M.D. Wurzburg, Chesham, Manchester.  
Nall, Samuel, M.B. Camb., Whaley Bridge, Stockport.  
Taylor, Seymour, M.B. Aberdeen, St. Thomas's Hospital, S.E.:

The following were admitted licentiates on April 28:—

Barns, John Gay, 9 Falmouth Road, S.E.  
Davies, David Samuel, 2 Queen Square, Bristol.  
Dunoon, William Archdeacon, M.D., Croydon.  
Evans, Arthur Owen, St. George's Hospital, S.W.  
Fenton, Herbert Alfred Hill, 1 Cumberland Street, S.W.  
Havell, Charles Graham, St. Mary's Hospital, W.  
Heaven, John Cook-stler, 145 Kennington Road, S.E.  
Heskin, Theophilus, Stratford-on-Avon.  
Hulgrave, Augustine, 40 Reelworth Street, S.E.  
Little, Ernest Muirhead, 18 Park Street, W.  
Marsh, Thomas Alfred Perry, Bristol.  
Marsh, William Aspinall, Hindley, Wigan.  
Mottice, Richard Iram, M.D., 17 Horton Road, E.  
Mudge, Thomas Henry Traevs, St. Bartholomew's Hospital, E.C.  
Newmarsh, Bernard James, 35 Doughty Street, W.C.  
Ozanne, Frederic Newell, St. George's Hospital, S.W.  
Penny, William John, King's College Hospital, W.C.  
Phipps, Edgar Vivian, St. Luke's Hospital, E.C.  
Smith, Ernest Sutton, 7 Fitzroy Road, N.W.  
Taylor, Henry Herbert, 4 Morden Terrace, S.E.

South London School of Chemistry and Pharmacy.—The following prizes were awarded to the successful competitors at the examinations ending the 2nd B course, and presented on the 30th of April, 1881:—Senior Chemistry Medal, Mr. Thomas; Junior Chemistry Medal, Mr. Shaw; Botany Medal, Mr. Ball; Pharmacy Medal, Mr. Walker; Materia Medica Medal, Mr. Key.

## NOTICES TO CORRESPONDENTS.

✉ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

MR FORSTER (Darlington) will please receive our best thanks.

DR. A. D. (Sheffield).—The reference to religious beliefs in the correspondence referred to is to be deprecated. We are always anxious to avoid religious controversy in our columns, and do not hesitate to strike out such references when we notice them in letters intended for publication. The line in this instance escaped our observation.

J. W. M. (Monmouthshire).—You were quite right in including diphtheria and croup in your list of infectious diseases to be notified to your local board. The latest Bill on the subject—now before Parliament—includes diphtheria in its schedule, and croup is so closely related to diphtheria, and so much dependent on insanitary conditions, that it certainly ought to be bracketted therewith.

POOR-LAW MEDICAL CONSULTATIONS.—J. C. M. writes: "I have been lately appointed under the Poor-law Act a dispensary medical officer. Some time since I was called in consultation by a neighbouring dispensary doctor in a case of midwifery through the *relieving officer* in the proper form. I should be obliged if you would let me know (1) to what fee I am entitled from the guardians, and (2) whether they should pay me car-hire (as I had to drive a distance of about ten miles to meet him, and was obliged to be absent for about nine hours)?"

[You are entitled to the same fee as you would receive for similar service in a private case, and if your services were formerly retained by the officer of the guardians you can recover that amount. No fee is fixed, but two guineas is the usual amount, car-hire being also paid for when the journey is lengthened and expensive.—ED.]

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.—The directors of the Society held their usual quarterly meeting on Wednesday, April 13th, at 5 p.m., Dr. Pitman, V.P., was in the chair. Applications for relief were read from 69 widows, 14 orphans, and

4 recipients of grants from the Copeland Fund. A sum of £1,250 was recommended to be distributed at the next quarterly court should the Visitors report favourably on the cases. There were no fresh candidates for membership or for relief. It was resolved to advertise once a quarter in the medical journals with the desire of making the Society better known. Dr. Temple, Dr. Self, Dr. Cumberbatch, Dr. Augustus Brown, Mr. Spencer Watson, and Mr. Vasey were the members selected to fill the annual vacancies in the directorship. The annual general meeting is to be held May 18th, at 5 p.m.

DR J. O. F.—We purpose devoting a series of articles on the evil to which your letter points.

MR. J. O. B. (Manchester).—The placard is beneath notice.

MR. H. E. CLARK will find the matter referred to in another column.

INDIRECT ADVERTISING.—A correspondent sends us a copy of the *Medical Chronicle* in which appears an article headed "New Instruments in Surgery," and which is an abstract from our columns of the proceedings of the Clinical Society of London in connection with a vein-brooch for the cure of varicose veins, &c., introduced by Mr. A. Baird Douglas, Surgeon, of Hounslow. Our correspondent asks if we approve the insertion of articles of a purely professional nature in the lay papers. To this question we unhesitatingly reply—No! There are, of course, articles at times in all medical journals of as great interest to the public as to the profession, to which, if not of personal advantage to the individual, there can be no objection; but the one before us is of the nature of a personal advertisement, and, therefore, in bad taste, as tending to lower the status of the profession.

ROYAL INSTITUTION OF GREAT BRITAIN.—At the annual meeting on Monday, May 2, Dr. Bowman, F.R.S., Vice-President, in the chair, the annual report of the Committee of Visitors for the year 1880, testifying to the continued prosperity and efficient management of the Institution, was read and adopted. The Real and Funded Property now amounts to above £85,400, entirely derived from the contributions and donations of the members.

#### PUNCH'S SONGS OF THE SCIENCES.—MEDICINE.

OH, would you study medicine, get learning anatomical,  
First fill your mind with all the lore of muscles and of veins;  
The names that they can boast of sound, you'll say, extremely comical,  
But you must learn them ere you try to ease our aches and pains,  
To grin derisively you use the *Musculus risorius*,  
The *Sternocleidomastoid* serves to turn the head away;  
We'll land upon Bell's Island, nor will think the work laborious,  
To cross the *Pons Varolii* a many times a day.

In course of time you'll learn, no doubt, the laws of Physiology,  
With all that Foster, Carpenter, and Huxley well must know;  
We'll hope you'll pay attention to Professors of Pathology,  
And gaze on all the wonders that the microscope can show.  
You'll find how blood goes through the lungs, and how they're  
Oxidising it;

How certain foods can do us good, while others do us harm:  
The body's like a steam-engine, 'tis really not surprising it  
Should take a regular amount of fuel to keep warm.

With Chemistry, and Pharmacy, and Surgery, and Botany,  
And Jurisprudence Medical, I fancy you will find  
Enough to fill a busy brain—that is, if you have got any;  
You cannot cure the body till you've amply stored the mind.  
You'll come when we are ill, like some benevolent inquisitor;  
Or gallant feats of Surgery shall startle all the town;  
While plunging into Lunacy you may become a Visitor  
Appointed by the Chancellor, like Doctor Crichton-Browne.

Here, surely, is a grand career—to cure our poor humanity  
Of all the ills to which our flesh is heir—a noble strife  
To wage against each fell disease, disorder, and insanity—  
To wrest the victory from death, and give the patient life.  
And when you've studied all you can, in order categorical,  
When you have worked at every branch of science under sun,  
You'll find—the illustration's not my own, but is historical—  
You pick up pebbles on the shore,—you've only just begun!

A DISCOURAGING CASE.—If the headache is accompanied with atonic dyspepsia, and there is a clean tongue with weight and oppression of the epigastrium, nitro-muriatic acid will be found serviceable before meals or three times a day. Dr. Day recommends the following formula in his work "On Headache."—

R	Tinct. nuc. vom.	..	..	} ss ℥i ;
	Acid. nitr. dil.	..	..	
	Acid. hydrochl. dil.	..	..	
	Tinct. aurant. . .	..	..	
	Aque pure, ad.	..	..	℥vi ;

Misce. A tablespoonful in a wineglassful of water three times a day

MR. HARRISON YOUNG.—Your "Notes on a Case of Constipation Simulating Typhoid Fever" shall appear in an early number.

OBSTETRICAL SOCIETY OF LONDON.—This day (Wednesday), at 8 p.m., Specimens will be exhibited. The President, "On a Case of Phlegmatia Dolens with Lymphatic Varix"—Dr. Galabin, "On a Case of Extra-uterine associated with Intra-uterine Festation, in which Abdominal Section was performed."—Mr. George Rigden, "On Statistics of Midwifery in Private Practice."

EPIDEMIOLOGICAL SOCIETY.—This day, at 8 p.m., Mr. John Spear, "On the Wool-sorter's Disease, or Anthrax Fever."

HARVEIAN SOCIETY.—Thursday, May 5, at 8.30 p.m., Dr. John Williams, "On a Case of Ovariectomy during Labour."—Mr. James R. Lane, "On Experiences of Antiseptic Surgery."

ROYAL INSTITUTION.—Friday, May 6, at 8 p.m., Hon. Geo. Brodrick, "On the Land Systems of England and Ireland."

NEW BOOKS AND NEW EDITIONS.—The following have been received for review since the publication of our Past List March 30th:—"A Guide to the Examinations at the Royal College of Surgeons" (4th Edit.), by F. J. Gant, F.R.C.S. "Ninth Annual Report of the Local

Government Board for 1879." "The Physical Signs of Cardiac Disease," by Graham Steell, M.D. "Students' Guide to Case Taking," by F. Warner, M.D. "The Detection of Colour Blindness," by C. Roberts, F.R.C.S. "Students' Guide to Medical Diagnosis" (6th Edit.), by S. Fenwick, M.D. "The Factors of the Unsound Mind," by W. A. Guy, M.D., F.R.S. "On Strangulated Veins of the Uterus," by T. B. Buckler, M.D. "The Human Voice," by J. Farrar, L.R.C.P. "Drugs that Enslave," by H. H. Kane, M.D. "The History of Salt," by E. Marlett Boddy, F.R.C.S. "On the Diseases of Children," by Wm. Henry Day, M.D. "The Disposal of Refuse," by W. Sedgwick Saunders, M.D. "Archives of Laryngology" (Vol. II.), by Louis Elaberg, M.D. "A Text-book of Practical Physiology," by W. Stirling, M.D. "What shall be my Practice," by E. Diver, M.D.

#### VACANCIES.

Carrickmacross Union, Raferagh Dispensary.—Medical Officer. Salary, £40, and £15 as Medical Officer of Health. Election, May 13.

Carlou Union, Ballickmoyler and Newtown Dispensary.—Medical Officer. Salary, £120, and £20 as Medical Officer of Health. Election, May 12.

Durham County Hospital.—House Surgeon. Salary, £100, with free board and lodging. Applications the Hon. Sec., the College, Durham, not later than May 16.

Stourbridge Dispensary.—House Surgeon and Secretary. Salary, £133, with apartments, &c. Applications to be sent, under cover, to the Hon. Sec., Dispensary, Stourbridge, on or before May 21.

Leeds Union.—Assistant Medical Officer. Salary, £100, with board, apartments, &c. Applications to be sent to the Clerk to the Guardians on or before May 9.

Sherburn Hospital, Durham.—Resident Medical Officer. Salary, £250. Applications to the Rev. the Master, Sherburn House, Durham, before May 20.

Torbay Hospital and Provident Dispensary, Torquay.—Senior House Surgeon and Provident Medical Officer. Salary, £100, &c. Applications to the Hon. Sec., not later than May 30.

#### APPOINTMENTS.

EWBANK, H., L.R.C.P. Ed., M.R.C.S.E., Senior House Surgeon to the General Hospital, Cheltenham.

HODSDON, J. W. B., L.R.C.P., L.R.C.S. Ed., Resident Physician in the Royal Infirmary for Sick Children, Edinburgh.

JACOB, E. H., M.A., M.D., Demonstrator of Physiology to the Leeds School of Medicine.

LOYD, J. J., L.R.C.P., L.M., House Surgeon to the Denbighshire General Infirmary.

MAHOMED, G., M.R.C.S.E., Resident Medical Officer to the Bourne mouth Dispensary.

MILLER, H. L.R.C.P. Ed., M.R.C.S.E., Medical Officer for the Witham District of the Brainree Union.

RYGATE, B. R., M.B., M.R.C.S.E., District (St. George's-in-the-East) Surgeon to the Royal Maternity Charity.

SHERWOOD, A. P., L.R.C.P. L., M.R.C.S.E., Medical Officer for the Kastbourne and Seaside District of the Kastbourne Union.

WHIFF, R., L.R.C.P. Ed., M.R.C.S.E., Medical Officer for the Burton District of the Kendal Union.

YOUNG, W. MUSEN, M.D., Assistant Medical Officer to the Suffolk County Asylum.

#### Births.

PHILLIPS.—April 28, at Albin Place, London Road, Reading, the wife of H. Heygate Phillips, M.D., of a son.

#### Marriages.

BLAKE—MOUNSEY.—April 28, at Goosnargh Church, Lancashire, Henry Blake, M.B., of Great Yarmouth, eldest son of H. Blake, M.D., Deputy Inspector-General A.M.D., to Lucy Agnes, eldest surviving daughter of Lieut.-Colonel Mounsey, of Preston.

MAURICE—CLARK.—April 28, at Christ Church, Folkestone, B. Maurice, M.B.C.S., Brighton, to Margaret, eldest daughter of Samuel Clark, M.D., of Folkestone.

#### Deaths.

BERNARD.—April 24, at Elm Lawn, Dundrum, Michael Chas. Bernard, M.B., T.C.D., L.R.C.S.I., in his 71st year.

COOPER.—April 29, at 20 Moor Street, Soho Square, London, Henry Cooper, M.R.C.S.E., in his 67th year.

LYSTER.—April 20, at his residence, 72 Devonshire Road, Prince's Park, Liverpool, C. E. Lyster, M.D., F.R.C.S.I., aged 46.

SCOTT.—April 28, at 4 Dean Terrace, Edinburgh, Wm. Scott, M.D., F.R.C.S. Ed., aged 87.

STOKES.—April 16, at Mullingar, Gabriel Stokes, M.D., aged 74.

WARREN.—April 8, at Malta, after a short illness, Wm. Henry Warren, L.M., M.D., Mem. Obst. Sect., M.R.I.A., Surgeon P. and O. of Australia, and formerly of the South City Dispensary, Dublin.

**PRIVATE INSTRUCTION** in CHEMISTRY, TOXICOLOGY, &c.—SOUTH LONDON SCHOOL OF CHEMISTRY and PHARMACY.—A separate Laboratory has been fitted up for the exclusive use of medical gentlemen qualifying for the various University examinations, or for medical officerships, who can therein receive private instruction in Practical Chemistry, Toxicology, &c., for long or short periods at stated hours. For fees, apply to W. Baxter, Secretary, South London Central Public Laboratory, Kennington Cross, S.E.

### THE LUMLEIAN LECTURES ON BRIGHT'S DISEASE.

Delivered before the Royal College of Physicians.

By REGINALD SOUTHEY, M.D. Oxon., F.R.C.P.;  
Physician and Lecturer on Clinical and Forensic Medicine at  
St. Bartholomew's Hospital.

#### LECTURE III.—Abstract.

THE lecturer, discussing the anatomical structure of the kidney, insisted on the peculiar adaptability of the organ to the work it had to perform, and especially drew attention to the "safety-pump" arrangement of its parts, to secure efficiency under all conditions. Von Nussbaum's observations on the living kidney of the triton, displayed in a wet chamber under the microscope, revealed the fact that the glomerules vary in size, accordingly as they are or are not flushed with blood; the neck of the ampulliform capsule shortens; the size of the glomerule is remarkably affected by the blood-pressure through the tuft. The sum of the pressure exerted by the distended glomeruli is very considerable, and Cohnheim's suggestion is consequently a reasonable one, that the Malpighian bodies are the spots where blood and blood-plasma, under undue pressure, most easily find their way into the urine tubes. If the endothelium over the tufts be swollen up, albumen can and does transude here. Experiments have shown that directly the pressure upon the tufts in the Malpighian bodies is so great that the inflow *per vas afferens* exceeds the outflow *per vas efferens* the tuft becomes distended to its maximum; further pressure is followed by transudation of albumen or migration of blood-cells.

We are familiar, now, with the fact that curable cases of kidney disease often seem the most alarming at first, being abrupt and acute; while the more obstinate and incurable lesions may co exist with apparent health and the least possible disturbance of renal functions. Gregory in 1831, and Bartels after him, most clearly insisted on the truth, in accordance with which less attention is to be

paid to casts and albumen and sediment of urine than to its quality during the twenty-four hours, as indicative of functional capacity.

Bamberger's secondary form of Bright's disease, which differs only in causation from the primary kind, is that which is most commonly encountered; and its commonest exciting cause is chronic phthisis, a disease that is found associated with fifteen per cent. of all the cases of morbus Brightii of whatever kind. Moreover, two-thirds of the whole number are white or mottled kidney forms. Cardiac valvular lesions are associated with a large number of atrophic kidneys, and arranging the primary causes of the kidney affections, we see it occupying a conspicuous place. The order of these exciting causes may be thus arranged: Phthisis, heart disease, gravidity, disease of the urinary outlets, suppuration, alcoholism, and scarlet fever low down in the list. Alcoholic excesses are the cause of a much larger number of fatal terminations than is usually supposed, a fatal form of acute parenchymatous nephritis being associated with it. Two cases in proof of this statement were those of a young lady and gentleman, the former given to secret drinking, the latter the victim of protracted drunkenness. After death the kidneys in each case were found large, swollen, pale-coloured, and soft; their capsules easily detached. They were typical samples of acute parenchymatous nephritis. Few patients, in fact, die after attacks of delirium tremens in whom the urine is not either albuminous or suppressed.

The following tables, compiled from the post-mortem records of St. Bartholomew's Hospital, are highly instructive. The first shows the form of kidney disease in 550 fatal cases. The second deals with 358 fatal cases of granular kidney; and the third with 141 cases of large white or mottled kidney. The fourth table deals with 55 cases of amyloid kidneys:—

TABLE I.

Granular Cases—Males 223, females 135	...	Totals 358
White or Mottled Kidneys—Males 101, females 40	...	141
Amyloid Kidneys—Males 23, females 13	...	35
Acute Post-scarlatinal Nephritis	...	16

Grand total ... .. 550

TABLE II.—358 Fatal Cases of Granular Kidney.

	No of Cases.
Without dropsy at death ... ..	272
Presented heart-hypertrophy ... ..	241
"  valvular lesions and hypertrophy ... ..	96
"  dropsy ... ..	86
"  cerebral apoplexy or softening ... ..	79
"  acute pneumonia or bronchitis ... ..	41
"  phthisis ... ..	40
"  pleurisy ... ..	35
"  pericarditis ... ..	27
"  peritonitis ... ..	8
"  cirrhosis of liver ... ..	20
"  simple serous effusions ... ..	16

"  "  ... ..	11	Phthisis.
"  "  ... ..	5	Lung œdema.
"  "  ... ..	3	Acute bronchitis.
"  "  ... ..	2	Lung gangrene.
"  "  ... ..	3	Empyema.
"  "  ... ..	2	œdema of glottis.
"  "  ... ..	2	Abscess.
"  "  ... ..	2	Carcinoma.

TABLE IV.—35 Fatal Cases of Amyloid Kidney.

Of whom, 28 cases presented heart normal.	
"  13  "  "  phthisis.	
"  7  "  "  great dropsy.	
"  4  "  "  slight anasarca.	
"  5  "  "  no trace of dropsy.	
"  3  "  "  peculiar atrophy of heart.	
"  2  "  "  valvular cardiac lesions.	
"  3  "  "  empyema.	

In connection with these tables should be added the fact, not shown by them, viz., that in 38 out of 141 cases of large white kidney uræmic symptoms preceded death. In the absence of a special record of these signs, it is to be assumed that the more gradual kidney disease is, the more tolerant the system becomes of blood overloaded with nitrogenous excreta, and the less probable is the occurrence of sudden eclampsia. Dropsy of the brain, Traube notwithstanding, has no connection with uræmic convulsions. Dropsy and serous effusions appear to be Nature's conservative actions, by which she stores away, often in silent and insidious innocuity, large amounts of urea, which, if circulated in the blood, had hardly failed to have provoked most marked poisoning symptoms.

The larger the amount of dropsy, the less the heart hypertrophy, and *vice versa*. With heart hypertrophy, you have increase of blood-tension, and restoration of

kidney functions, and diminution of dropsy, in chronic renal disease; and, doubtless, the heart hypertrophy is a most salutary conservative effort upon the part of the individual whose kidneys present circulatory obstacles and excretory incapacity under ordinary blood-pressures.

The atheromatous changes in arteries generally found to accompany Bright's disease had been noticed by Bright, and later by Dr. Wilks; but Toynbee first commented on the enlargement of smaller arteries in the organ, and Dr. George Johnson in 1850 and 1868 described the remarkable thickening both of arterial walls and of Malpighian capillaries in chronic disease.

The change ascribed by Johnson to muscular hypertrophy, Gull and Sutton (1872) gave as hyaline fibroid metamorphosis of the outer coat of arterio-capillaries, while continental writers generally agree that it is an affection of all the walls of the arteries, but the intima most of all, and call it "endoarteritis obliterans," something nearly allied to atheroma. Dr. Johnson originally described the hypertrophy, which he showed to be widely distributed in the body, as assisting in urging forwards the blood in the vessels; but in 1875 he said it was a consequence of resistance to the force exerted by a hypertrophied heart, and secondary to the latter. He rejected the other explanations offered, in favour of the view that the increased action of the arterioles is the result of over stimulus conveyed to them through the nerves from the capillaries, these being irritated by the noxious character of the blood they contain. It would be reasonable, however, to find the same reason for hypertrophied vessels as for hypertrophied heart, viz., overwork in every case.

In 1872 Gull and Sutton described the changes they had observed in arterio-capillaries, and said "in granular contraction of the kidney, a hyaline fibroid substance may be seen between the convoluted tubules; it exists in considerable quantities around the Malpighian bodies, and in still greater amount in and around the walls of the minuter arteries." Dickinson described, without naming, the same change. Klebs, Weigert, and Cohnheim's descriptions all apply to a similar hyperplasia, and from them the argument that atrophic changes succeed impeded blood supply is warranted. The hyaline-fibroid changes differ from atheroma in being greatest in the arterioles and capillaries, and it is an undoubted pathological change. Gull and Sutton attribute to it the production of red granular atrophic kidney; they think it may exist also in the body without implicating the kidney, and cannot, therefore be due to mere impurity of the blood from renal disease. The facts in support of this view are, however, too few in number to merit its acceptance, leading as it must to belief in the assumption that granular kidney is one symptom only of general vascular degeneration. Ewald attributed the hypertrophy of the small arteries to the increased pressure they had to support, and calls Gull and Sutton's hyaline-fibroid, "endarteritis fibrosa." Chronic inflammation is the cause he assigns for the change which involves all the tissues of the vessel, whose lumen is gradually encroached on and narrowed by the intima. He does not agree that kidney hypertrophy is caused by vascular degeneration, but thinks the kidney change first in the order of events, having found only one case, a man of thirty, to support Gull and Sutton's views. He believed the capillary changes and the renal degeneration progressed *part passu*, followed by compensative hypertrophy of the heart; next increased tension, undue pressure on the walls of the arterioles, muscular hypertrophy and thickening of them, and finally, structural degeneration in consequence of perverse nutrition. Dr. Leyden, in 1880, has reopened the subject, urging that there are two kinds of vascular change, both being "arterio-sclerosis;" one Gull and Sutton's hyaline fibroid, and the other a thickening inseparable from ordinary atheroma. Dr. Leyden cites cases in support of his views that the kidney is not necessarily degene-

rated as a consequence of general vascular degeneration, but they are hardly conclusive to this end.

If hyaline-fibroid vascular degeneration is the cause of the interstitial renal disease, as Gull and Sutton and Dr. Leyden assert, and because it is sometimes far advanced when the renal disease is only beginning, and mainly because it well explains the hypertrophy of the heart and some of the associated mental and cerebral symptoms of renal atrophy, it must be admitted that we have more facts in support of endarteritis obliterans as a change following upon ordinary renal degeneration, than of its being the cause of it; and, from the paucity of the facts in support of Gull and Sutton's hyaline-fibrosis theory, we infer that this is a rare change even in well-marked atrophied kidneys.

Gull and Sutton's original argument was, that this arterio-capillary change was widespread throughout the body; that atrophied kidney was one symptom of it only; that it was a premature growing-old or wearing out of the blood-vessels, which led to structural local degeneration situated principally in the kidneys, the brain, the spinal cord, the heart, and the lungs—local degenerations which have been elevated to a too great importance, and regarded apart as local diseases; that in the kidneys, and presumably in the lungs and in the liver—three of the most vascular glands in the body—these fibrosis-changes may be expected to manifest themselves most prominently. The changes in the kidney entail, however, a peculiar train of symptoms, from the function of this gland; and these have been moderately well understood and studied, under the name of Bright's disease. The kidney is found atrophied in a peculiar way; and the disease, which is really a general one with some remarkable local tendencies, is, they say, wrongly attributed entirely to the organ, which is found to have suffered predominantly. Thus they would altogether separate the small red kidney from Bright's disease.

The view generally held in France and Germany that the vascular changes mainly affect the inner coat, is an endarteritis obliterans, is admittedly not that put forth by Gull and Sutton. It relates to a distinctly different condition, and herein lies the explanation of the differences of opinion. Dr. Johnson is describing one thing, a very apparently real muscular hypertrophy, although one difficult to estimate; for the state of contraction or dilatation and the mode of treatment after death, whether by injection or otherwise, of an artery, makes a singular difference in the apparent thickness of its muscular walls; Drs. Gull and Sutton are describing another; while Lancereaux, Bartels, Charcot, Rendu, are referring to a third. All are right, and each is only wrong in misunderstanding the other.

Side by side, and therefore most conveniently placed for comparison, in the same volume (xxviii) of the Pathological Society's "Transactions," 1877, may be read three papers upon this interesting subject from the pens of Drs. Gull and Sutton, Johnson, and Mahomed. It is encouraging once more to find that a feature of such importance in the history of Bright's disease, as these vascular changes are, should have been first notified by his countrymen. But we are not of opinion that they detract at all from the entity of Bright's disease. At most, Gull and Sutton establish one form of renal degeneration secondary to a vascular degeneration. But when the renal degeneration has reached the stage of imperfect or insufficient urinary depuration, the symptoms are in the main those of ordinary Bright's disease.

Bamberger found hypertrophy of the heart in 344 out of 807 cases of primary Bright's disease, and in explanation of the conditions several theories have been advanced. Dr. Bright insisted that the impure blood exerts an unwonted stimulus on the muscle of the heart, and prevents the easy passage of the blood through the small vessels, the left ventricle being consequently excited to unusual contractions. This explanation is, however, insufficient, since the greatest amount of hypertrophy is found to co-exist with a condition of blood in which no maintained impurity

can be assumed to have existed, to have stimulated the heart, or obstructed the passage of blood through the vessels. Further, in many other diseases besides those of the kidney, impurity of the blood does not by any means surely induce hypertrophy of the heart, so that although there are forms of Bright's disease undoubtedly associated with impure blood, this factor alone will not serve to explain the overgrown heart. Traube offered a double explanation, viz., obstruction of peripheral circulation, and excess of water in the blood; the order of events being thus described by him: obstructed circulation, increased arterial tension, supplemented or not by abnormal hydræmia, dilatation and hypertrophy of the heart. Bamberger thus arranges the objections to Traube's theory:—1. The hypertrophy by no means accompanies the kidney which presents greatest destruction of its vascular channels, to the exclusion of all other forms of Bright's disease. 2. It occurs where there can be no question of any obstacle to the amount of circulation through the kidneys, for injection fluids pass readily enough, as in the small contracted kidney they undoubtedly do. 3. Mere obstruction to the passage of the blood will not suffice to explain it, either situated at the Malpighian tufts, because this is quickly remedied by collateral blood-direction in the kidney itself through the arteriolæ rectæ, or placed anywhere else in the body by tying an artery, because of the ample room offered to collateral blood-flow. Cutting off a limb, which is surely suppression of a large vascular area, will not produce it; and, as Rosenstein showed, a dog, one of whose kidneys was removed, presented, many months afterwards, no hypertrophy of the heart. 4. Traube's theory, if it throws any light upon the hypertrophy of the left heart, throws more upon the hypertrophy of the right heart that frequently accompanies it.

Dr. Johnson, in his earlier writings, like Bright, attributed hypertrophy to impure blood, but at a later period he referred it to general arterial alteration, by which the left ventricle is excited to redoubled action. It is, however, more likely, or at least as likely, that the hypertrophy of the heart is provoked by increase of blood-tension independently of spasm of the arterioles; and that the alteration in these small arteries is, as it obviously is in aortic regurgitant disease, secondary to the hypertrophy of the heart; and, as Bamberger justly objects, it fails to throw any light on the hypertrophy of the right heart.

Von Buhl's theory is that the affection of the heart is due to an inflammatory process taking place in the heart, and stimulating it to over action. He thinks that the granular kidney and the hypertrophy of the heart occur coincidentally, but wholly independently of each other, and own some common source of origin, and that this is some sub-acute wide-spread inflammatory action. He found evidence of such past inflammatory changes in the endocardium or the valves, in the heart's muscular substance, and in the pericardium, in 67.7 per cent. of all cases of granular atrophy of the kidney. He also found relative constriction of the aorta, or an abnormal ratio between the circumference of the aorta and the length of the left ventricle, which he regarded as an accessory stimulator of the hypertrophy of the heart. But then he leaves wholly unexplained a great many cases of hypertrophy of the heart, in which he can find no traces of past inflammatory action, and refers them to fatty degeneration.

Sir W. W. Gull and Dr. Sutton's theory refers the hypertrophy of the heart to a change in the blood vessels of the heart itself, similar to that which they observed and described as occurring in various parts of the body, their arterio-capillary fibrosis; a change which, occurring in the kidney, led to granular atrophy; in the dura mater, brain, and spinal cord, to various manifestations of sclerosis. Their publication appeared before that of Von Buhl, and perhaps suggested in some measure the lines of his inquiries and the opinions at which he arrived. It certainly serves to explain the occasional hypertrophy of both sides of the heart, and many of the wide-spread pathological lesions, bronchitic, pneumonic, hepatic, and cerebro-spinal symptoms and complications sometimes

manifested. Further, that a wide-spread increase of nuclear interstitial tissue in the capillary meshwork is one of the most manifest pathological changes that occur in chronic Bright's disease, and especially in the very chronic forms of atrophied kidney, we can entirely confirm by our own experience, and prove by abundant microscopical specimens in our possession. But, at the same time, we are bound to state our conviction that the muscular hypertrophy of the arterioles is an equally well-established fact, which Gull and Sutton cannot be supposed to have either overlooked or denied, and is a matter wholly independent of the thickening of the capillaries and of the external tunic of the artery, which it usually, but not invariably, attends. Why it was not more prominently alluded to by them, we cannot tell. But we have seen marked thickening of the capillary walls in the kidney when little or no noticeable hypertrophy of the muscular coat of the arterioles existed in chronic renal disease, and, believe it, therefore, to be the most important factor in the production of the increased blood-pressure and hypertrophy of the heart; in saying which it must be observed that we hold Ewald's views, and had done so for some time, quite independently of having read them. Ewald thus propounds his opinion in Virchow's *Archiv*, Band lxxi, p. 453. 1. In point of events (and in causation), he believes in the existence of the kidney affection; 2. The blood-deterioration ensues; 3. The altered blood, he says, offers an obstacle to the capillary circulation everywhere.

The compensative, not degenerative, nature of the hypertrophy of the heart and muscular wall of the artery have been advocated by Bartels and Cohnheim, and it may be observed by means of the sphygmograph. The pulse wave is bold, high-peaked, square-topped, and indicates a stage at which the heart is vigorous and the patient in granular atrophy, passes excess of urinary water, enough for ordinary purposes, and occasional small amounts of albumen. The pulse tension is lower in chronic hæmorrhagic nephritis, but the other conditions are little altered.

Ewald found that in every case of interstitial nephritis (kidney-cirrhosis), the arteries were hypertrophied as well as the heart; that, in the mixed forms of kidney disease—interstitial and parenchymatous (or, as we should prefer to call them, mere chronic forms of hæmorrhagic nephritis, mottled kidneys becoming granular, &c.), two-thirds of the cases presented hypertrophy of the heart and the walls of the vessels, while one-third presented hypertrophy of the heart only; whereas, in the pure parenchymatous cases—i.e., the most acute forms of nephritis (those with smallest discharge of urine and greatest dropsy, and shortest course), the heart was only found hypertrophied to the extent of about thirty-three per cent., and the arterioles were not affected at all.

Bamberger concludes that the increased blood pressure is caused by a perpetual excess of water in the circulation—itsself due to kidney disease. This increased blood-pressure must produce either dropsy, dilatation, or hypertrophy of the heart. Dilatation will be favoured by impaired nutrition, lax fibre, or tissue wasting diseases. Hypertrophy will occur in persons otherwise vigorous, of healthy digestion, and on whom the strain is gradually induced.

In granular contracting kidney, as Virchow and Thoma have more recently shown, certain remarkable alterations in the circulation through the kidney itself takes place in the course and progress of the disease; and I may quote myself, for the fact is one I stated years ago, in 1865, first, as the blood's passage through so many Malpighian tufts is impeded by their wasting and gradual extinction, the topmost cortical layers become less vascular, the vasa ascendia dwindle at their tops, and the direct branches to the arteriolar rectæ enlarge, by collateral blood-flux; and further, in many instances, especially in those larger Malpighian bodies, those placed nearest to the vasa recta, the vasa efferens, can be seen passing straight on into the vas efferens, without capillarising in the glomerule at all, and the circumtubular

networks here become dilated and highly blood-filled. This is the stage in which the heart is highly hypertrophied, and is a well-nourished muscle, with no trace of degeneration attaching to it; when the kidney is red and highly vascular, the blood-passage through it is short, the blood-current swift; and when the secretion of urine is very little abnormal, except in quantity, which is notably increased, and in specific gravity, which is preternaturally low. This is the stage of thirst and polyuria.

But, later on, the blood-mass sinks again, the kidneys' power of excretion gains upon the body's faculty of absorbing, or the blood's power of maintaining, so much water; then, as the blood-pressure subsides, the dilating cause disappears, the dilatation of the heart's cavities diminishes, but the hypertrophy does not stand still, it only becomes more concentric.

Then if we follow the life-history of the case of granular kidney further, we find that the impurity of the blood increases as the discharge of urine diminishes, the capillary obstacles from impeded nutritional peripheral interchanges increase, the friction is greater, and the heart has a harder and harder burden cast upon it, while its own nutrition is inadequately provided for; it degenerates, becomes unequal to drive the blood on, and the end comes quickly by uræmic symptoms or lung-œdema, or apoplexy.

Bamberger's theory is, as he admits, a modified Traube's theory; and it must be allowed to be the only one, except Von Buhl's and Gull and Sutton's, which at all faces the facts, and endeavours to explain the hypertrophy of both sides of the heart.

Bright's disease must be regarded as a convenient term under which to group certain important clinical phenomena associated with variously marked forms of inflammatory degenerations of the kidney, all of which possess something in common. The symptoms are mainly the consequence of a local disease. Gull and Sutton's hypothesis, that interstitial atrophic kidney is a distinctly separate form is untenable. Bright's disease is a real entity, and while granular atrophy may be a consequence of arterio-capillary fibrosis in its most gradual and complete degree, it is the renal disease which gives the characteristic features to the widespread general phenomena.

Bright's disease may be primary or secondary, acute or chronic; its consequences may be best followed by recollecting what the functions of the kidneys are, and what their non-fulfilment must effect. These are primarily, to maintain the blood at a proper specific gravity, by removing excess of water and excess of salts from it, as well as special nitrogenous excreta. The duty of the kidney is to regulate the quantity, as well as the quality, of the blood—a matter sometimes lost sight of. If the blood-fluid be allowed, at any time, to swell like a flood, either dropsy, the transudation of its more watery part, must take place, or the blood-channels must dilate. If excess of salts accumulate in the blood the specific gravity or weight of the blood-column must rise, and increase the friction through the capillaries; it comes, then, to strain first the channels in which it is confined, the chambers of the heart, and the blood-vessels, and to tax unduly the pump-power of the heart, and the muscular walls of the arteries. If nitrogenous excreta cannot escape by the kidneys, they accumulate in the blood, or must make a way out for themselves by vicarious channels; maintained in the blood, they interfere with the chemical nutritive changes, perhaps effect that general lowering of the body-temperature which is characteristic of the uræmic state; making their passage out by the intestines, skin, or serous membranes, they surely sooner or later, provoke inflammatory changes. Just in so far as Bright's disease is held to comprehend all these phenomena of suddenly or gradually abrogated renal functions, is it a useful name.

The treatment of disease is wisely pursued by those only who possess an accurate knowledge of it; and to an increase of this our efforts have been directed.

## REMARKS ON DISSOLUTION OF THE NERVOUS SYSTEM AS EXEMPLIFIED BY CERTAIN POST-EPILEPTIC CONDITIONS.

By J. HUGHLINGS JACKSON, M.D., F.R.C.P., F.R.S.,  
Physician to the London Hospital, and to the National Hospital  
for the Epileptic and Paralysed.

### INTRODUCTION.

(Continued from page 332.)

ON some parts I have worked for years in ignorance of what prior workers had done. I had, for example, arrived at the hypothesis of local exhaustion of nervous centres from epileptic discharges years before I knew that Todd and Robertson had stated it. I had come to the hypothesis of "loss of control," to use Thompson Dickson's expression, long before I found out that hypothesis had been propounded by him and Anstie. I may add to the above that I do not know of any previous attempts made to study Insanities on the principle of Dissolutions. In this book, too, cases of Dissolution beginning in the highest centres are considered in relation to cases of Dissolution beginning in subordinate centres.

In this paper a subject which is really exceedingly complex will be artificially simplified. It is absurd, if the account given purports to be thorough, to simplify a really complex subject by the very simple process of omitting the difficulties. But it is fair to artificially simplify it if we acknowledge and point out the simplifications. One simplification is omission of consideration of symptoms from disease of the cerebellum. All the difficulties I can think of will be stated.

There is an important thing I must mention at once which will, however, be more conveniently considered in detail later on. It is impossible to study cases of disease of the brain methodically if we confuse psychological states with nervous states. We must be thoroughly materialistic in our method so far as is practicable. What will be said later on on psychological states is said in order that we may study without psychological bias the material basis of mental disorders; that we may see how to investigate in a brutally materialistic manner. I consider what we may metaphorically call stages in Dissolution of mind simply to get to know the corresponding stages of Dissolution of the nervous system. In some of the earliest of the following sections this distinction will seem to many to be occasionally ignored. I sometimes speak of mental symptoms "from" disease of highest cerebral centres, along with physical symptoms from disease of lower centres. It would seem to some that one ought at once to insist on the distinction. But to those readers who have only considered disease clinically and who make no distinctions betwixt psychology and the anatomy and physiology of the Nervous System, this procedure would be most inconvenient.

In this paper I intend to speak chiefly of temporary conditions of some epileptic patients after their seizures. By these cases we can best illustrate Dissolution beginning in the highest centres. I must first speak of the epilepsy itself.

**SECTION I.—The Definition of Epilepsy.**—I have defined epilepsy as a condition in which there is a sudden excessive transitory discharge of some part of the cortex. Under this definition epileptiform convulsions are included. But except for purposes of illustration I shall say nothing of epileptiform seizures. By epilepsy here shall be meant solely what are called cases of epilepsy proper or genuine epilepsy, the epilepsy of nosologists. Clinically, the cases are those in which loss of consciousness is the first thing or nearly the first thing in the paroxysm. Anatomically, they are cases in which the discharge begins in some part of the highest centres, these centres being the anatomical substrata of consciousness.

From the foregoing it follows plainly that strictly we ought to speak of several kinds of epilepsy which are grouped under the term epilepsy proper. Doubtless there are at least as many kinds as—no doubt, more than—there are kinds of epileptiform seizures. In other words, the "discharging

lesion" may be of different parts of any of the several divisions of the highest centres. I suppose it may be in the front or back of either hemisphere; so far dividing the highest centres geographically. Dividing anatomically, the discharging lesion may be in the highest motor or highest sensory centres of either side; dividing after psychology in the motor or sensory substrata of either object or subject consciousness. There will be at least as many different epileptic seizures, differently seated discharging lesions, as there are different "warnings" of the paroxysm. So then we ought, for a thorough investigation of epilepsy, to note the particular kind of paroxysm as well as the post-paroxysmal condition. We have indeed in each case to note the kind of warning (mode of onset of the paroxysm), the particular kind of paroxysm in its stages of development, and the particular post-paroxysmal condition. But to start with we shall, as is customary, speak of epilepsy proper as if there were but one epilepsy.

**SECTION II.—The Importance of the Study of Post-Epileptic Conditions.**—I beg the reader never to lose sight of the fact that our particular task is narrowed to the condition of patients when their paroxysms are over, when the discharges causing them have ceased. Sometimes patients act more or less elaborately in this post-paroxysmal stage. There is, for an example, epileptic mania (post-epileptic I think). A consideration of cases of epilepsy on this aspect is very important, not only as illustrating Dissolution, but in other ways. 1. *Clinically.*—(a) Unless we have studied many kinds of Actions after epileptic seizures of different degrees of severity, and especially Actions after the slightest we shall overlook the epileptic nature of some of our patients' cases altogether, for example, we may mistake epilepsy for hysteria. We may occasionally be consulted because a person suddenly acts strangely, violently, or passes into a state which resembles somnambulism, and nothing will be volunteered as to epileptic attacks. Unless we have very carefully studied the phenomena of very slight seizures of epilepsy we shall misinterpret these cases; we shall dwell with exaggeration on the striking, and neglect the essential; the thing is to ferret out the quasi-trifling signs of a transitory fit. It is of more importance for diagnosis and treatment to inquire about such symptoms as transient pallor, movements of mastication, turning up of the eyes, than to note with care the "interesting" symptoms of elaborate quasi-somnambulism. (b) The cases alluded to are some cases of temporary Insanity. The term Insanity is used in its application to these cases in a sense far wider than the legal, popular, or even clinical, sense. It is to include, for example, such cases as those in which there are merely grotesque actions as well as cases of those patients who require restraint because their actions are violent and dangerous. Not only cases of epileptic (post-epileptic, I think) mania, but cases in which the actions are but slight caricatures of normal actions, such as mixing cocoa in a dirty gallipot, used for the cat's food, with a mustard spoon. I think that the careful investigation of temporary post-epileptic states is one of the very best ways of beginning the special study of insanity for practical as well as for scientific purposes. In many of the cases, as in that from which the second illustration given above is taken, the actions admit of easy analysis.

(2) *Socially or Medico-Legally.*—We can show that an epileptic after a slight seizure may act in a very purposive-seeming way when unconscious; so that, if his actions be injurious to others he is irresponsible. This of course has long been done by alienist physicians, but the public requires iteration of facts. I take the following summary of Trousseau's opinions from the Report on Forensic Medicine, in the first year-book of the New Sydenham Society. I suppose it to be founded, in part at least, on the work done by Morel and Fabret:—

"TROUSSEAU.—On Sudden and Irresistible Determinations in their relation with Epilepsy. L'Union, vol. ix, 540.

"If a man has committed a murder without motive, purpose, premeditation, or passionate emotion, in a state

of sobriety, and in the view of all—that is to say, in the absence of all those conditions under which murders are commonly perpetrated—M. Trousseau would be prepared to aver that the impulse to the crime must *almost certainly* have been the result of an epileptic seizure, even if he had not witnessed such seizure. If the act has been committed immediately after an epileptic seizure, attested by credible persons, the medical witness may assert positively that the impulse was irresistible. M. Trousseau cites numerous remarkable cases, showing that sudden and irresistible impulses, under which acts are committed which may or may not have important results, occur frequently during the minor epileptic attack (*petit mal*), or after the convulsive paroxysm; and that such acts are accomplished without the agent's knowledge, and are not remembered by him. The temporary suspension of free will renders him for the time irresponsible for his acts."

(3) The cases are important in the methodical investigation of that part of the Anatomy and Physiology of the nervous system which most evidently corresponds to Psychology. In this regard they are, to speak figuratively, experiments which disease has made on some part of the chief divisions of the Organ of Mind.

(4) The cases are examples of Nervous Dissolution.

It is from the last-mentioned standpoint that we shall, in this paper, chiefly consider the cases. But we must also consider them clinically and physiologically, or we shall not properly see how they come under the principle of Dissolution. All the facts are obtained clinically, and without a good clinical knowledge of epilepsy we should ignore some of the most important of them and misunderstand others.

Now we must widen our field; so far we have spoken of post-epileptic actions only.

#### MACEWEN'S OPERATION FOR GENU VALGUM. (a)

By FREDERICK ALCOCK NIXON, F.R.C.S.I.,  
Surgeon to Mercer's Hospital, and Lecturer on Anatomy in the  
Ledwich School of Medicine, Dublin.

MR. PRESIDENT AND GENTLEMEN:—Having carefully considered the various operative procedures devised and practised by different surgeons for the relief of that distressing deformity called genu valgum, I purpose laying before the Society the notes of a case which I have successfully treated by Macewen's method; a method which I think has not yet met with that recognition at the hands of Irish surgeons which it deserves, and which it will no doubt, at some future period obtain, when its simplicity and safety are more fully appreciated.

The notes are briefly these:—Patrick F., æt. 18, a labourer, native of the county Clare, was recommended by my friend Dr. Singard, and placed himself under my care in Mercer's Hospital.

On admission, he was found to be of delicate physique, and suffering from pustular acne, his right leg was the subject of well marked genu valgum, the left showing also a slight tendency toward the same affection.

On placing the boy upright with his knees in contact, there was an interval of eleven inches between the inner malleoli of the tibiæ; on the malleoli being placed in contact, the right leg crossed completely over a point of the left and well to its opposite side. No definite history of his having suffered from the common diseases of early life. His hygienic surroundings were no doubt faulty, there was no evidence of the affliction being hereditary; so far as could be ascertained the water supply of his district was pure, he worked in the open air, and enjoyed a full supply of sun light; he suffered from "growing pains" which, from the description he gave, were clearly due to physiological determinations of blood to the bones during the progress of their development. They were worst in the affected limb.

(a) Read before the Surgical Society of Ireland.

He attributed his deformity to using a shovel, which he pushed with the inner side of his right knee.

That the disease was of rachitic origin was, I believe, conclusively proved by the fact of the other limb showing a tendency toward genu valgum.

There was no contraction of the biceps, this and the other muscles generally being soft and flabby; there was no contraction of the external or morbid relaxation of the internal ligament; there was no arrest of development of the external condyle.

The inner condyle appeared to be abnormally developed on its inner side and flattened in its antero-posterior measurement. It was, moreover, unduly elongated, the lower third of the femur was the seat of a well marked curve, the convexity of which was directed inward. There was no obliquity of the tibial epiphyses. Thus it will be observed there were present in this case two out of the three factors which produced this deformity, the third and probably the least important having the obliquity of the tibial epiphyses being absent as I believe is the rule in about two-thirds of the recorded cases.

The operation was performed with strict antiseptic precautions. Anæsthesia being fully induced, so as to obviate muscular spasm. The limb was placed on its outer side on a sand pillow, the sand being moistened to prevent it flying. An incision, one inch in length, was made with one stroke of the knife straight down, and the bone, at a point half-an-inch in front of the tendon of the adductor magnus, and half-an-inch above the upper level of the external condyle, the knife being used as a director, the osteotome was introduced along its side, and pressed against the bone, care being taken not to disturb the periosteum more than could be avoided.

The instrument was driven far behind and within outwards and forwards, and again from before and within outwards and backwards, much caution being used not to divide the compact tissue on the outer anterior and posterior surfaces of the bone.

The femoral diaphysis having been thus partially divided by a jar-like wedge-shaped incision by a series of different sized osteotomes, I was readily able, by binding the limb across my chest, to place it in a straight position.

I applied a Liston's splint with a short posterior one, reaching from the gluteal fold to the centre of the calf, and had the patient removed to bed.

He suffered considerably from surgical shock for some time, also from loss of blood. The outer layer of Lister's dressing having become stained, I was obliged to remove it; the bleeding, which was altogether venous, and, I believe, from the bone having been previously arrested by our resident surgeon, Mr. Gaffney.

After this the patient had no untoward symptom. He had no constitutional disturbance. His temperature never, at any time, rose above 99° Fahr., and on the fourteenth day, when the dressing was removed, the wound was found to be completely healed, without any evidence whatever of suppuration. He was discharged at the end of the fourth week with a limb straight, strong, and useful, and when I last heard of him, about three days ago, he had returned to work.

Of the operations proposed by Barwell, Reeves, Ogston, Chiene, &c., Macewen's seems to me by far the safest and best. It is well above the important structures which secure the articulation, and it leaves the epiphysis intact, and so obviates the danger of arrest of development of the bone, still the results obtainable are highly satisfactory.

The object I had in bringing forward this case is to elicit discussion, did time permit, on the relative merits of the different operations proposed for the relief of this affection.

This case itself is also of some interest, as being the first treated in Mercer's Hospital by Listerism, and as being, so far as I know, the first occasion upon which Macewen's operation has been performed in Ireland.

## Clinical Records.

### LAENNEC HOSPITAL, PARIS.

Under the care of M. LEGROUX.

#### Case of *Uræmia* caused by *Infarction of the Kidney*.

Reported by M. DE BRUN, du Bois-Noir. (a)

FOR more than a year there has been, under the care of Dr. Legroux, in Piorry ward, a patient affected with right hemiplegia, consecutive to mitral disease (stenosis and insufficiency). The hemiplegia was stationary, and the cardiac symptoms had, for some months, caused little trouble, thanks to repose, and the administration of digitalis, when suddenly, on the 3rd January, 1881, the patient was seized with a general malaise and anorexia, accompanied with vomiting of glairy matter.

At the evening visit the pulse was found to be thready, the features drawn, the skin cold, especially at the extremities. A sensation of constriction at the abdomen, but no pain or meteorism. No motions.

Jan. 4th.—Patient better. Skin warm, pulse stronger. A bottle of seditz water given. At the evening visit, symptoms, same as previous evening. Injection of sulphate of soda. Some evacuation.

5th.—Same state. Abdomen hard; sensitive to pressure. Rectal examination revealed nothing. Micturition infrequent, and small in quantity. Brandy given.

6th.—Still no motion.

R. Ol. ricini, 40 grains.

Ol. crotonis, 3 drops.

During the night a motion produced.

7th.—Patient went to stool twice in the day, but passed no water. At the evening visit catheterism brought about a spoonful of urine; albuminous, and of normal density. Head-ache.

8th.—Slight icterus. Cough; some subcrepitant râles at the right base. No micturition.

9th.—Tongue dry. Catheterism again produced about a spoonful of urine. Intense cephalalgia. Subcematose state.

10th.—No micturition. Patient in a state of somnolence, from which she wakes only to be delirious. Temp. 35·8° C.

11th.—No micturition. Patient died in the evening.

At the autopsy we found: Heart hypertrophied, mitral stenosis and insufficiency. Brain: several spots of cerebral softening. Kidneys: the right greatly congested, and showing two moderate sized old infarctions. The left showed numerous recent infarctions with which it seemed crammed. There was also intense congestion of the cortical substance, congestion at the base of the pyramids of malpighi, whilst the rest of the pyramid is quite pale. Lungs: In the base of the right lung three small apoplectic centres.

Worthy of remark in this case was—

1. The fact of anuria produced by renal infarction.
2. The peculiar manifestations of this occurrence, the first symptoms of which suggested intestinal obstruction.
3. Lastly, the considerable part which we must give in the actual case to the hyperæmia of the kidneys. The renal embolisms would have been absolutely insufficient by themselves to cause this anuria, if they had not set up a violent congestion of the whole organ, a congestion especially intense at the base of the pyramids of malpighi. This flexion may be, by its importance, analogous to that observed in the lung consecutive to embolism of that organ.

WE regret to announce the sudden death of Dr. Falconer, of Bath, at his residence, a few days since. Deceased was of robust constitution and presence, and his death has given a severe pang to those who had the pleasure of his acquaintance. For many years he has been the respected Honorary Treasurer of the British Medical Association, and was unanimously elected president when it was decided to hold the annual meeting in Bath in 1878. Dr. Falconer was a F.R.C.P. Lond., M.D. Queen's University in Ireland, F.K.Q.C.P.I., M.D. Edin., D.C.L. Durham, &c.

## Transactions of Societies.

### SURGICAL SOCIETY OF IRELAND.

THE closing meeting of the Session of 1880 81 was held on Friday evening, April 1, in the Albert Hall, Royal College of Surgeons.

Dr. M'CLINTOCK, President of the College, in the Chair.

THE PRESIDENT apologised for the absence of the honorary secretaries, one of whom (Mr. Tufnell) was confined to bed, while the other (Mr. Richardson) had been examining in the College since four o'clock that day, and was not yet emancipated to take his part in the proceedings of the Society. He therefore called on Dr. William Roe, as the junior member of the Council, to act as hon. sec. *pro tem*.

Dr. ROE read the minutes of the previous meeting, which were confirmed.

#### TRACHEOTOMY.

Mr. HENRY GRAY CROLY wished to place on record a case of tracheotomy in which unusual difficulties were encountered. The patient, Edward Smith, æt. 28, who was in attendance to be examined, had been always healthy until October, 1874, when he had an attack of syphilis. Subsequently he had a secondary syphilitic eruption, for which he was treated with benefit in one of the Dublin hospitals. About twelve months afterwards he had another syphilitic eruption, and he then took small-pox. During convalescence he caught cold, from which he got a severe sore throat, with loss of voice. The sore throat affected him occasionally until October last, when the attack became aggravated, accompanied by a brawny swelling of the neck. On the 5th November last he was admitted into the City of Dublin Hospital suffering from cellulitis of the neck. He had the erysipelatous blush from the os hyoides down to the sternum. As usual in those cases, he had considerable difficulty both in breathing and swallowing. In fact he had all the symptoms of low fever accompanying the cellulitis of the neck. Incisions were made in the lines of safety—one in the line of the trachea; another higher up over the larynx; besides incisions on each side. The patient did not derive the same amount of relief from opening the cervical fascia that he had seen others get after that operation. At the same time the man was suffering from deep ulceration on the back of the pharynx, familiar to all as described by the late Mr. Colles. The deeper ulcer of the two extended on a level with the epiglottis. The lower part was deep, and the discharge was constantly irritating the patient's windpipe, so that the food was sticking into it. He was treated for the ulceration by the usual local applications—nitric acid, and afterwards mercurial fumigation, in addition to constitutional treatment. That which was of greatest interest in connection with the subject was what subsequently occurred. On the 1st January last, during his convalescence from the cellulitis of the neck and the deep ulceration on the back of the pharynx, he caught cold and got inflammation round the epiglottis, and also the ordinary symptoms of syphilitic laryngitis. On the night of January 7 he was seized with an urgent attack of laryngeal spasm induced by the falling down of a portion of mucus in the deep ulcerated part of the back of the pharynx. This was wiped out; but he had two attacks afterwards, and the dyspnoea became so urgent he had to remain in a sitting posture, and the resident pupils were in attendance on him during the night. In fact, the case became so serious that Mr. Ashe had the instruments ready, expecting that any moment either he or Mr. Croly might be called upon to open the windpipe. In the morning he got attacks of laryngeal spasms as well. Sitting on the side of the bed covered with cold clammy sweat, his condition at three o'clock in the day became so alarming it was thought he might at any moment die. To afford a chance of saving his life Mr. Croly was called on to perform the operation of tracheotomy. In the early part of the day Mr. Tufnell saw the case, and concurred in the opinion that in all likelihood the operation would become necessary before the evening. The operation was performed in the theatre, the patient having been placed under the influence of an anæsthetic. Mr. W. Thomson, Dr. Carte, and other surgeons, besides several students, were present. As was a common occurrence, the patient, when placed under the influence of the anæsthetic ceased to breathe. Mr. Croly made the incision in the line of what was called the high operation for tracheotomy. He

had to cut through the infiltrated tissues of the neck, where the patient was recovering from an erysipelatous attack, and the tissues were infiltrated and brawny. In consequence of impending suffocation it was with great difficulty the brawny tissues were cut through. There was very little bleeding; but that might be explained by the structures being matted together. Though he changed the knife and used a second, it was with great difficulty he cut through the tissues down on the trachea, and when he reached the trachea and fixed it with a hook it was also with difficulty he got through the trachea itself. He made a free opening into the windpipe, but no air escaped through the wound. The patient was then almost dead. Fortunately, the thought struck Mr. Croly to introduce the end of his little finger into the wound to ascertain the cause of the air not coming through, being satisfied it was fully opened. He then found there was a lymphic exudation flowing up the line of the trachea before the line of incision. Had he introduced the tube into the wound the thing would have been blocked, and nothing but a post-mortem examination would have revealed the actual state of affairs. As it was, he had to force a passage into the trachea to make room for the tube, and when it went down the full length the patient took a deep inspiration. The patient's breathing then went on uninterruptedly, and he made a rapid and satisfactory recovery. During the after treatment of the case the factor from the wound was most abominable, and was only corrected by keeping the antiseptic spray applied over the region of the operation in the room where he was. Taking it all round, tracheotomy was one of the most serious and fatal of surgical operations. But the case was interesting in several points of view—in consequence of the complication of cellulitis with ulceration and laryngeal inflammation, on account of the brawny tissues of the neck, and lastly the condition of the windpipe, which almost prevented the patient from breathing when the tube was opened.

The PRESIDENT—Having regard to the impending suffocation would be apprehensive of administering a strong anæsthetic; but he had no experience of such cases, and he would be glad to hear an opinion on that point.

Mr. CROLY, without replying, desired to observe that it was after consultation the anæsthetic was administered.

Dr. KILGARIFF said the case recalled two difficulties that often arose in the performance of the operation. First of all he would be in favour of administering anæsthetics in order to prevent the patient struggling and interfering with the manipulation of the operation. As to the difficulty of fixing the trachea and opening it, his practice had been this, that having exposed the trachea, he secured the tube with two tenacula, one on each side, entrusting the instrument to assistants. Thus the tube was kept perfectly steady. Having a tenaculum on each side there was no difficulty in opening the windpipe. The knife could be freely introduced into the tube, which might be then slit up to any desired extent. Before his mind was a case in which he performed the operation. Having opened two or three rings of the trachea, no air entered. Of course he would not then introduce a tube. Air had neither entered nor left the lungs, and it was perfectly clear to him then, that the trachea or the tubes farther down must be blocked. The case was supposed to be one of diphtheria. It occurred a few years ago, when stomatitis and tonsillitis prevailed in the city, with fatal results in several instances. But the case in point was not, in his opinion, one of diphtheria, or he would not have acted as he did—he applied his mouth freely to the wound, and he removed clots of blood and imperfect casts of the tube. When he proceeded to perform the operation the patient's lips were of a livid plum colour, and the face deeply congested; but in a few moments afterwards the face became quite calm, and acquired the ordinary healthy appearance. The tube having been introduced, the child breathed freely afterwards. Dr. Baxter, who assisted him on the occasion, would corroborate what he had stated.

Dr. BAXTER said he had a distinct recollection of the case. The operation was performed about six years ago on a child about seventeen months or two years old. When about to begin the face was quite livid, but immediately on opening the larynx it was remarkable how the colour returned. However the case did not turn out a success.

Mr. CROLY replied. He did not think that Dr. Kilgariff's case had any bearing whatever on his own, because the difficulty of fixing the trachea had nothing to do with it. Every surgeon knew that fixing the trachea with two hooks, especially in treating children, was important. But his

point was the cutting through an infiltrated neck. In Dr. Kilgariff's case there was no infiltration. As to the colour coming back to the face, that occurred in every case of the kind. Thus the points mentioned by Dr. Kilgariff were of every day occurrence in tracheotomy. But the difficulties that occurred in Mr. Croly's case he had never witnessed before, and he had frequently done the operation for syphilitic disease and croup, and he was present at an operation by Mr. Corley in a diphtheritic case.

Mr. F. ALCOCK NIXON on

MACEWEN'S OPERATION FOR GENU VALGUM.

which will found on page 400.

Mr. KENDAL FRANKS said the subject of osteotomies in general was so fully debated at the last meeting, that there was little to be discussed outside Macewen's operation. He had performed that operation twice himself, and he intended to have read a paper upon it, but postponed doing so till the end of the session, when he found that Dr. Nixon preceded him on the list. The first case in which he performed the operation occurred two years ago. He did not publish it at the time for the same reason that a good many cases were held back, namely, that it was unsuccessful. The limb, which was crooked, he made straight, but two days after the child got scarlatina, accompanied by profuse suppuration at the wound, abscess in the thigh and round the leg, and the child died of exhaustion. That case did not prove or disprove anything, the scarlatina taking all merit or demerit from the operation. The second case he had about two or three months ago. A child, very poorly nourished, was admitted into the Adelaide Hospital with a leg at an angle of 145 degrees. He performed Macewen's operation under the spray, taking every antiseptic precaution. He went two-thirds through the femur, and used a chisel to make a wedge in the bone upwards and downwards. When the wedge was made, by the use of his hands alone he succeeded in making the bone perfectly straight. The bone did not break. Then the dressings were applied, and a bandage was put on from the foot to the hip, and over it an application of plaster of Paris, to keep the limb in position. The dressings were not changed for ten days. On removing them then the wound was completely healed, except a little abrasion of the skin where the incision was made. That was due to the irritation of the carbolic dressings. He dressed again antiseptically, and did not disturb the dressing for a week, when, on taking it off, he found everything healed. The child was kept in hospital to straighten the other leg by means of splints, the limb not being sufficiently crooked to justify an operation. Thus Macewen's operation was suitable in those cases, and under antiseptic precautions would lead to good results.

Dr. KILGARIFF said Macewen's operation, applicable to certain deformities at the knee-joint, was not by any means an original one, being almost identical with that proposed by Rhea Barton, of Philadelphia, in the year '39, or at all events, many years ago. However, Barton did not propose it for the deformity known as genu valgum, but for certain cases of ankylosis of the knee-joint. He had himself a single experience of the particular operation, having performed it a few years ago in a case of osseous ankylosis of the knee, in which the leg was at right angles to the thigh. Having cut down on the femur above the synovial membrane, he removed a wedge-shaped piece of sufficient size from the thigh bone, the wedge behind enabling him to place the limb in a favourable position. On removing the piece he straightened the limb. Suppuration took place, and although the treatment was fairly antiseptic at the time, the bones did not unite for two or three months afterwards. The case did very well. He had also had some experience of the deformity of genu valgum, and he wrote a paper on it as being the first in this country to perform the operation advised by Ogden. Since then he had had no opportunity of operating; but the result of that case was most gratifying. The patient was a delicate girl. He separated the internal condyle with a considerable portion of the femur above it, placing that condyle in normal relation with the outer condyle. The operation was conducted according to strict Listerism. In the first instance in which he operated all symptoms of inflammation, and even of tumefaction, disappeared after a fortnight, and in the second no ill effects whatever followed; the girl had now straight limbs, and she was strong and healthy. His experience in

that case would encourage him to perform Ogsden's operation again.

Mr. WILLIAM STOKES thought Dr. Kilgariff was hardly justified in saying that Macewen's operation and Rhea Barton's were identical or similar. There were important differences between those operations. For instance, the situation where the section of the bone was made differed in both. In one the section was made in the anterior aspect of the bone; in the other in the lateral. Again, in one the procedure by a subcutaneous operation—by a free incision down; and in the other it was done by the osteotome. Lastly, the operations were performed for extremely different conditions. If the foregoing did not constitute differences, he did not know what differences in operations were.

Mr. E. H. BENNETT entirely endorsed Mr. Stokes's remarks with reference to Dr. Kilgariff's criticisms, because he did not think that an operation such as Rhea Barton's tantamount to an excision of the knee-joint, was to be compared to the class of operations Mr. Nixon had recorded. The style of the operation and the class of wound were totally different, and the conditions for which they were adapted were totally different. The point Mr. Nixon raised had not been dwelt upon. Such operations performed by Irish surgeons were not many, simply because Irish knees were too straight for the proceeding. Speaking generally, the great principle of Macewen's operation was, first of all, that it was a section made by an osteotome or chisel, without any *debris* from the saw, and while made through an open wound, still a limited one, not such as would be made for an excision of the knee. On this point he might fairly criticise Mr. Nixon's communication, and dispute the priority he claimed in the performance of the operation, for it would be recollected that he had himself brought forward on the last night of meeting a paper in which he treated of the three cases, including four operations by Macewen's method in distinct localities; two on the tibia for deformity of the tibia, the type of Macewen's operation; a section of the femur beneath the trochanters, for the relief of the fracture; and also an operation on the elbow-joint. He did not think the place at which the operation was performed made any great difference.

Mr. CORLEY pointed out that communications on operations for the cure of genu valgum had been frequently before the Society, most successful cases having been recorded by Mr. Kelly, of Jervis Street Hospital, eight or nine years ago, the procedure being by a division of the external lateral ligament of the tendon of the biceps.

Mr. NIXON replied. A good deal of doubt seemed to exist in the minds of some members of the Society as to what Macewen's operation was. Mr. Franks in his remarks had stated that in the operation which he performed he used a chisel to make a wedge. If he did, that was not Macewen's operation at all. Mr. Stokes had anticipated his answer to the remarks of Dr. Kilgariff, but he would repeat that Mr. Rhea Barton's and Mr. Macewen's were wholly different, the great principle of Macewen's being that he did not remove any bone whatever.

Mr. BENNETT.—He decidedly states that on any occasion he pleases he removes a wedge.

Mr. NIXON said he was confining himself entirely to the operation of the section of the lower portion of the femur with the osteotome for genu valgum. He was not aware of the operation that Mr. Kelly performed eight years ago by the division of the external lateral ligament; but there were cases recorded of that procedure having been followed by disastrous results.

Mr. FRANKS.—I read his article carefully, and followed his directions as minutely as I could. I removed no bone either, but did exactly as he directed in his original article.

Mr. NIXON was under the impression that Mr. Franks said that he used a chisel to make a wedge.

Mr. FRANKS.—I passed the osteotome to form a wedge, but not to remove a wedge.

#### THE PRESIDENT'S ADDRESS.

The PRESIDENT said he must relieve their minds from the gloomy apprehension that he was going to give an address. Nothing was further from his intention. How the announcement that he was going to do so came on the notice paper he was at a loss to account for. However, he would venture to make a few cursory remarks. That was the last night of the fiftieth session of the Surgical Society, ending the

first half century of its existence. They might look back on the history of the past session with considerable satisfaction, the amount of work done being in no way inferior to any of its predecessors. During the session nine ordinary meetings were held. It would be desirable, as was done in nearly all the great English Medical Societies, to keep a record of the number of members that attended each meeting, and also the number of visitors. To do so would not impose extra trouble on the secretaries, because each member as he came in wrote his name in a book, and the porter could inform the secretaries of the numbers present. The record would show the progress of the Society by the interest attaching to its meetings. There had been twelve formal *original communications* made to the Society during the past session, some of them exhibiting a great deal of originality, and all of them care and industry. Besides, there had been shown twenty-one *pathological specimens*. The exhibition of recent specimens he considered an important and valuable part of the Society's work, and it was to be regretted that there could not be some discussion admitted under limitations upon those specimens. In many instances that would be desirable as affording a wholesome check or restraint upon the exhibitors, who would be cautious in their remarks when they knew what they said was liable to be commented upon and criticised. In the 28th rule it was stated, "That recent specimens, if desired, shall take precedence of all other communications; but in such cases no discussion shall be permitted thereon." It was but just to the authors of papers that that rule should exist, otherwise the discussion on recent specimens might push the papers out of the running altogether. At the present time, when there was such great haste in medicine and surgery to bring ideas forward and secure priority, to alter the rule would be an injustice, and would discourage men from reading and preparing communications. The only way, then, in which a discussion on recent specimens might be permitted consistently with the principles he had stated, would be with the consent of whoever was to read the first paper, but even this is obviously open to objection. A very important part—he was inclined to say the important part of the business of a Society like this consisted in the discussions. Oftentimes a paper was of little value itself, but it served as a hook on which to hang a valuable debate; eliciting an expression of the opinions of experienced men upon some important point of practice. He therefore thought the discussions formed the most important part of their proceedings. Throughout the Session, all the discussions, though occasionally a little warm and animated, had been conducted with strict propriety; at any rate, without any breach of the courtesy and the propriety of language that should always be maintained in any society of gentlemen. It was right and fair that there should be the freest expression of opinion on opinions put forward; but that was very different from casting an imputation on the character or veracity of an author. If there was not a certain freedom allowed in discussion, the debates would become milk and water sort of things, of no value or interest. He apologised for having been several times absent from the meetings of the Society. The loss, however, was all his own; because, on every occasion they had been, as they would be on every future occasion, able to find among themselves a more competent chairman. He had nothing more to add, except to express a sincere hope that they might all be permitted to meet there again under similar circumstances next November; and in the meantime, he urged those who had hitherto been zealous and industrious in bringing material and pabulum to the Society's meetings to continue accumulating facts and figures in the six months before them, thereby laying up a stock that would yield valuable communications in the ensuing session. In view of that, he would say in the words of Horace:

"Condo et compono, quæ mox depromere possim."  
The Society then separated.

#### ASSOCIATION OF SURGEONS PRACTISING DENTAL SURGERY.

WEDNESDAY, APRIL 20TH, 1881.

THOMAS EDGELOW, L.R.C.P., President, in the chair.

#### SOFT PALATE AND COMPLICATIONS.

MR. FRANCIS MASON, F.R.C.S., exhibited two patients from

St. Thomas's Hospital. The first was a child, *æt.* 9, upon whom he had operated successfully for cleft palate. The chief point of interest in the case was that the patient had been operated upon previously at another hospital, and not only had no union taken place, but the right side of the soft palate had completely disappeared, and from what cause it was difficult to determine. This circumstance rendered the case peculiarly unpromising for operative procedure, but by dint of free incisions the parts came well together, and the result was most satisfactory. Two operations were required, the soft palate being closed first; and after an interval of a month, the hard palate was dealt with by the so-called Langenbeck operation. There was no hare-lip in this case. The next patient was a young woman, *æt.* 24, the subject of a single hare-lip on the left side, complicated with a fissure extending completely through the hard and soft palate. Mr. Mason was indebted to Dr. Eyan Jones, of Aberdare, for the case. One point of interest rested in the remarkable fact that no operation had been performed on the lip in early life. In dealing with this case, which was by no means a promising one, Mr. Mason operated first on the palate, believing that the fissure in the lip would facilitate, as indeed it did, the steps of the operation. The soft palate was closed, and in order to relieve tension the bony palate was perforated and divided with a chisel, somewhat after Dieffenbach's plan. Partial union only took place, and this untoward result was probably attributable to the cold air entering the mouth through the fissured lip. He, therefore, thought it best before doing anything more to the palate, to close the fissured lip, and this operation he performed about a fortnight ago with marked improvement to the patient's personal appearance. He added, that he hoped in a short time to complete the closure of the palate, and in conclusion referred to a fact he had frequently noticed in connection with hare-lip in children and adults, that when a tooth is exposed to the air at the fissure of the lip, the tooth generally undergoes caries. In this instance the lateral incisor of the left side had become carious, and had broken off at its neck.

Mr. HENRY LONG JACOB, of Birkenhead, exhibited a second lower molar tooth into which the wisdom tooth had become impacted into its posterior aspect.

Mr. CRAIGIE brought forward a remarkable case of irregularity of the teeth in the upper and lower jaw, occurring in a young lady, *æt.* 13, and made some remarks on its treatment, &c., &c.

NOTICE has been given that an examination of candidates for ten appointments as surgeon in Her Majesty's Indian Medical Service will be held in London in August, 1881.

THE annual rates of mortality last week in the principal large towns of the United Kingdom per 1,000 of their populations were:—Leicester 12, Norwich 15, Sunderland 15, Leeds 16, Birmingham 17, Hull 17, Portsmouth 18, Oldham 18, Nottingham 19, Newcastle-on-Tyne 19, Edinburgh 20, Glasgow 21, Plymouth 21, Bristol 21, London 21, Sheffield 22, Brighton 23, Manchester 23, Wolverhampton 23, Liverpool 25, Salford 26, and Dublin 30.

OF diseases of the zymotic class in the large towns last week, measles showed the largest proportional fatality in Bristol, Newcastle-upon-Tyne, and London; the general fatality of scarlet fever and whooping-cough was considerably below the average for the season. Fever, principally enteric, was abnormally prevalent in Dublin. The 17 deaths from diphtheria, showing a decline from recent weekly numbers, included 6 in London, 5 in Glasgow, and 2 in Liverpool. Small-pox caused 75 more deaths in London and its outer ring of suburban districts, one in Birmingham, and one in Glasgow. None were registered elsewhere.

REGISTERED FOR TRANSMISSION ABROAD.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, MAY 11, 1881.

## SMALL-POX AND EPIDEMIC CONSTITUTION.

As illustrating the extent and virulence of the present epidemic of small-pox in London, we learn that, whereas the numbers of cases of that disease admitted into the hospitals under the Metropolitan Asylums Board were 253 and 777 in the last two quarters of 1880, they rose to 2,288 in the first three months of 1881; that the number of cases under treatment at the end of March was 899—that is greater than has at any time since 1877, been so; that the existing hospital accommodation is now quite inadequate for the subjects of that disease, and that further increase in extent of the epidemic is expected by those who study such subjects. All these circumstances give rise to certain reflections. One is this: Not many years ago we heard on all sides proclaimed the revelation of a new science—sanitary science. Before it epidemics were to be abolished, certain kinds of diseases, said, in the phraseology of the time to be *preventible*, were to be altogether suppressed; human life extended to a hundred years, that being the proper period to which, according to the principles of the new-born science, it *ought* to reach. For the purpose of carrying out extensive "sanitary" works and schemes very large sums of public money have been, and

continue to be, expended. No doubt the comfort and convenience of communities and individuals have been greatly enhanced thereby; but so far have so-called "sanitary schemes" been from putting an end to epidemics of small-pox, that the one now prevailing is actually more extensive and more severe in its nature than were some outbreaks of the same disease that prevailed years ago, and long before "scientific" sanitation had obtained a title of its present development, and before large special hospitals for the reception of patients suffering therefrom had been multiplied as more recently they have been.

Are we to explain this circumstance by the theories of contagion alone, specific poison alone, or pythogenesis alone? By none of these can we account for the outbreak of the disease in places and at times separated from each other by intervals of great but varying extent; for the development, culmination, decay, and disappearance, after a time, of the disease on such occasions; nor for the modifications which occur in the phenomena of various other affections, as observed during epidemic seasons. That in isolated instances, small-pox is contracted as a result of personal contact or communication with an infected person, is not to be gainsaid. On the other hand, the fact must not be ignored that the opponents of large hospitals, such as those provided for cases of this disease by the Metropolitan Asylums Board, have not succeeded in demonstrating that the presence of large numbers of patients suffering from it has, in reality, been instrumental in giving rise to a proportionally larger outbreak of the malady in the immediate vicinity of those establishments than has occurred in localities at a distance from them.

Neither is the theory of filth, whether of individuals, communities, or localities, of itself sufficient to explain the propagation of small-pox during epidemic periods; far less the origin of epidemics, although from the general conditions of classes thus situated, and of which dirt constitutes one item, like all other diseases of an epidemic nature, small-pox, when it does occur under such circumstances, acquires a degree of severity far greater than in localities, and among communities, whose general circumstances are more favourable. How, then, is the occurrence of an epidemic outbreak, such as the present, to be accounted for? Not, certainly, by restricting our cognisance to the points already enumerated. Are we then to fall back upon the abstraction to which from times the most ancient the term "epidemic influence" has been applied, and which, very recently has been, as in contempt, termed mythical, apparently because inappreciable, either by means of chemistry, or the microscope? It would seem that such is the case. Here, then, is what Dr. Guy writes on the subject of this "mythical epidemic influence." Every year has some atmospheric element, which neither thermometer, neither rain nor wind gauge, nor measure of moisture, nor test of ozone, can reveal to us, but only our records of sickness and death. One year it is such as favours small-pox, the next, perhaps, it will promote scarlet fever, or measles, or whooping-cough, or it will, so to speak, select from several forms of fever that one which shall fill the beds of our hospitals. This condition of air, of which disease itself is the only test, and measure was once called pestilence, but is now known as its "epidemic constitution. And this, whenever it acts

on the population with such energy that the disease which it favours affects large numbers of persons, that disease is calculated an epidemic. But this epidemic constitution, be it observed, is not its true and direct cause, but only its predisposed cause."

Dr. Parkin holds that there occur certain "pestilential epochs," during which the world is at frequent intervals devastated by epidemics, which travel in a determinate direction, from central or eastern Asia, to the west of Europe, and even to America; that during such epochs, all diseases, even such as are not considered communicable from one person to another, increase in frequency and in violence; that these epochs are, moreover, marked by epizootics and by blights, or diseases in the vegetable kingdom. Such an epoch is generally ushered in by the appearance of new diseases, or re-appearance of maladies that had become obsolete. He believes that the pestilential epoch is characterised also by mental diseases, and by delusions; also that we have entered upon a new period of epidemics, as instanced by the recurrence of small-pox, diphtheria, typhoid, carbuncle, typhus, scarlet fever, diarrhoea, the increase of epizootics, and the various maladies among fruits and vegetables.

How far the phase of the subject thus presented will repay the task of steady investigation remains to be seen, if, indeed, such a task be undertaken. If the recurrence of particular diseases as epidemics is ever to be looked upon, and investigated as one of the great natural phenomena of our existence, it may be that the laws in obedience to which that recurrence takes place bejoming ascertained, it shall be in the power of all those who succeed us, to prepare for, and to a greater extent than we, mitigate the severity of what, so far, is no more to be averted by the means adopted than are the phenomena of growth and decay, the seasons, tidal ebb and flow, the devastating hurricane, the thunderstorm, the drooping leaf, the hues of autumn, and so on.

#### THE CONFLICT OF MEDICAL TESTIMONY.

THE frequent conflict of medical opinion in medico-legal cases (we honestly think Glasgow is notorious for it) is not calculated to increase lay respect for the medical profession. Thoughtful outsiders may well be excused if they seriously question whether there is really such a thing as medical science at all, and whether the pretensions of so-called allopaths are not equally chimerical with those of homœopaths. Undoubtedly, medical men are themselves to blame for an immense amount of the ridicule and well-merited contempt which the profession has thus vicariously to suffer. The idea, evidently so frequently acted upon, that the medical witness can, consistently with honour and his duty to his profession, go into the witness-box and prevaricate or distort facts in favour of his employer, is one radically wrong in principle. It is the duty of the medical man simply to tell the honest truth as the facts present themselves to him. We have a higher respect for the legal profession than to believe that any counsel would deliberately be guilty of untruth to save his client. It is his duty, as we take it, to see that the prosecution take no unfair advantage of his client, and bring into prominence the aspects of the case favourable to him.

He has to unravel a tangled mass of circumstances in which deduction forms the main feature. In the case of medical men it is usually quite otherwise, as their principal duty is to speak of objective phenomena. It is true they have to draw conclusions; but it is frequently sufficiently apparent whether these legitimately follow from the premises. This unfortunate conflict of medical testimony in relation to objective phenomena was recently brought into pitiful prominence in the case of *Smith v. the Caledonian Railway Company*, tried before the Lord Justice Clerk, at the Glasgow Circuit Court, on Friday the 29th ult. The pursuer sustained injuries in the Penilee accident, and claimed as damages there for £5,000. We have every sympathy for railway companies in the matter of these actions, believing as we do that many of them are trumped up for the mere purpose of extorting money; and railway companies have a perfect right to protect their own interests. The recuperative influence of a cessation of legal hostilities, particularly if favourable to the pursuer, is often amusingly striking. The question in this case was, whether the pursuer had or had not completely recovered from a serious accident, as certified by Dr. James Wallace, of Greenock?

The medical aspects of the case will be better understood by entering somewhat into the detail of Dr. Wallace's report, according to which the patient was seen by him on the evening of the accident (8th September last), when the following condition was disclosed: Patient was found deeply depressed by shock, being pale and cold, and having heart's action much enfeebled. He complained much of pain in the back, in the front, and in both sides of the chest, the former, from subsequent discoloration, having evidently been severely bruised. He had also great pain in the calves of both legs, particularly the right; in both ankles; and in right big-toe. Both legs had been severely bruised. The symptoms of shock continued for nearly two days, during which Dr. Wallace considered the patient to be in great danger; and even after he had fairly rallied he had frequent tendency to fainting fits, which necessitated more than ordinary care in applying the requisite dressings to his limbs. In a few days the abraded integument on the upper third of the right leg sloughed, and exposed a large bruised clot, and thereby necessitated free incision. The patient all the while kept sleepless, nervous, and depressed. Recovery took place slowly, the patient not being able to leave his bed for a period of five weeks, nor to leave his house for sixteen days longer. Even then, for the first three days, he was able to go out only in a cab, and for a few hours only. For ten days more, though able to walk to business, he could not remain more than a few hours daily, because of pain in the head, nervousness, and tendency to fainting, and it is only during the last fortnight (December 6th, 1880) that he has had the courage to go on his ordinary journeys to Glasgow. He still sleeps ill (December 6th, 1880), is easily startled, has frequent tendency to fainting, and a peculiar sensation in the region of the heart, the action of which is rather weak and which will necessitate great care in future movements.

Looking at the foregoing statement from the aspect of subjective and objective phenomena, the former are con-

the patient seems to have been pained all over. Pain in such cases as this is a symptom on which little or no reliance is to be placed. The objective phenomena, however, seem to have been sufficiently serious; and, as already observed, the question which arose was, whether the patient had, at the date of the trial, completely recovered from the effects of the accident?

On the 30th December, in conjunction with Dr. Whiteford, Dr. Wallace examined the patient, and found that the nervousness, headaches, and the peculiar feeling of the region of the heart were away; and on examination of the heart the sounds were perfectly normal, and the patient expressed himself as entirely well. On the 20th of April (last month) Dr. Wallace made another examination associated with Dr. James Dunlop and Dr. Whiteford. He attributed the fainting fits to some disorder of the digestive functions. He did not think the patient's heart was affected; he was the same physically as before the accident. Dr. Samuel Moore, of Glasgow, said that fainting fits, nervousness, and weakness about the heart, were what he expected after so severe a shock. He did not think the effects were entirely removed, and it was possible patient might yet live to feel the effects of it. His heart was not satisfactory; its action was quick and rapid. After such a shock his nervous system could not bear the same strain; and if there was any strain of the nervous force, that would produce a tendency to fainting. Patient had no dyspeptic symptoms about him. The general weakness of his condition and of his heart could prevent his passing for an insurance office. Dr. Hector Cameron thought it a fair inference that these faintings were due to some disabled condition of the heart. He did not think there was much amiss with the heart now. He did not think there was anything wrong with the stomach. Dr. James Whiteford, of Greenock, as the result of an examination on 30th December, concluded that the patient was quite recovered. On April 20th he found the physical condition quite as good as on the day of last examination. The heart's action was sound and regular, and the breathing uninterrupted, the brain and spine sound, and the general functions satisfactory. The fainting fits, he thought, were due to the dyspeptic condition of the patient. The fainting fits were not, in his opinion, attributable to the accident. The surgical shock had completely passed away on the 30th December. He would give pursuer a certificate for life assurance. Dr. James Dunlop, as the result of last examination on April 20th, said that having examined pursuer's back, head, all the important organs, his heart, his lungs, and he did not discover evidence of organic disease anywhere. The pulse was 72, quite normal. From the state of pursuer's tongue he thought he had a biliary derangement; and his skin was also of a yellowish tinge. He did not look a dyspeptic man. He appeared to be quite recovered from the accident.

Now, looking at such evidence as this, can we feel surprised if twelve or thirteen sensible men would form a mean estimate—if any estimate at all—of its value? There must be ignorance, misconception, or something else somewhere; and such exhibitions have a most damaging effect on medical testimony in general.

One feature in the foregoing evidence is specially to be deprecated; and that is the indulgence in vague and

indefinite terms to conceal palpable ignorance, thus—"some disorder of the digestive functions;" "almost killed;" "heart not satisfactory;" "strain of the nervous force;" "some disabled condition of the heart;" "not much amiss with the heart now," &c., These are simply unmeaning terms, and convey no special significance as factors in a medico-legal investigation.

Altogether, so far as concerns the medical testimony in this case, we think the ends of justice would have been equally well served if the medical savans were dismissed from the bar, and the question of the pursuer's health made to depend on a "toss up!"

## Notes on Current Topics.

### Non-Combatants at Majuba Hill.

IN the report of the disaster to the British troops at Majuba Hill, on February 27, published in the London *Gazette* of the 3rd inst., the following passages occur:—Corporal Farnier, of the Army Hospital Corps, showed a spirit of self-abnegation, and an example of cool bravery, which cannot be too highly commended; while the Boers closed with our troops near the wells, Corporal Farnier held a white flag over the wounded, and when the arm holding the flag was shot through, he called out that he had another. He then raised the flag with the other arm, and continued to do so until that also was pierced with a bullet. He has been recommended for the Victoria Cross, and well has he earned that distinction. Nothing could exceed the devotion of Drs. Landon and Cornish, both of whom lost their lives in the discharge of their duties. Dr. Landon and two of the Army Hospital Corps were shot down while attending to the wounded, the former being mortally wounded. Dr. Mahon speaks most highly of the conduct of William Bevis (sick berth attendant), for his coolness and courage during the action, and for the invaluable assistance he rendered afterwards. Of Surgeon Mahon himself Commodore Richards writes in the highest terms. He alludes to the performance by him of his duties in action under circumstances of "extensive personal peril," and recommends him specially to the notice of the Admiralty; further, that "Dr. Mahon behaved with great bravery and coolness." Honour to whom honour is due! Nor is it often that, as in the present instance, the official report of a military action, written by a medical officer, finds its way into the pages of the *Gazette*.

### The Royal Commission on the Medical Acts.

THE following are the terms of the Commission to inquire into the Medical Acts, of which we gave the *personnel* last week:—

"Whereas it is of importance to all classes of Our subjects that the conditions under which persons are permitted to represent themselves as qualified medical practitioners should be such as to afford the best attainable security for their skill and knowledge in medicine and surgery.

"And whereas powers in relation to the education and

examination for a grant of medical degrees, diplomas, or licences to medical practitioners are by various statutes and charters vested in certain universities, medical colleges, and other bodies in the United Kingdom.

"And whereas under 'The Medical Act, 1858,' and the Acts amending the same, the General Council of Medical Education and Registration was constituted, and vested with a superintendence over the exercise of the said powers, and also with entering in a Register of Medical Practitioners, and removing therefrom the holders of certain medical qualifications obtained in the United Kingdom, exclusive of those obtained in Our Colonies or in Foreign States.

"And whereas by the last-mentioned Acts certain exclusive privileges were conferred on the persons so registered, and persons not so registered were placed under certain restrictions, disabilities, and penalties.

"And whereas divers representations have been made in Parliament and otherwise, and both from Our subjects in the United Kingdom, and from the Governments of Our Possessions out of the United Kingdom, in relation to the unsatisfactory position of the above matters.

"And whereas we have thought it expedient that, with a view to legislation, further inquiries should be made into the above matters, and that a Commission should forthwith issue to inquire into the grant of medical degrees, memberships, fellowships, licences, and other diplomas by universities, colleges, and bodies in the United Kingdom, and the courses of education and examination, payments, other conditions required as a preliminary to such grant, and into the skill and knowledge which such degrees, memberships, fellowships, licences, or diplomas represent; and further to inquire into the conditions and manner under or in which medical practitioners are entered in and are struck off the Register of Medical Practitioners, and the privileges of registered and the disabilities of unregistered practitioners, and the position of medical practitioners so registered in Our possessions out of the United Kingdom, and the position in the United Kingdom of medical practitioners educated in Our possessions out of the United Kingdom or in a Foreign State.

"And further to inquire into the constitution, functions, powers, and procedure of the General Council of Medical Education and Registration, and their relation to the above-mentioned universities, colleges, and bodies, and to the medical profession.

"And further to inquire into the result of 'The Medical Act, 1858,' and the Acts amending the same, and into all matters dealt with by those Acts.

"And for the better effecting the purposes of this Our Commission, We do give and grant unto you, or any three or more of you, full power and authority to call before you, or any three or more of you, such persons as you shall judge necessary by whom you may be the better informed of the truth on the subjects herein submitted for your consideration, and every matter connected therewith; and also to call for, have access to, and examine all such books, documents, papers, and records as may afford the fullest information on the subjects of this inquiry; and to inquire of and concerning the premises by all other lawful ways and means whatever.

"And Our further will and pleasure is that you, or any three or more of you, do report to Us, with all convenient speed, under your hands and seals, the result of your inquiries into the above matters, and what amendments are required in the above-mentioned Acts, and what provisions it is expedient to make in the matters above-mentioned, or any of them.

"And We further will and command, and by these presents ordain, that this Our Commission shall continue in full force and virtue, and that you, Our said Commissioners, or any three or more of you, may from time to time proceed in the execution thereof, although the same be not continued from time to time by adjournment.

"And for the purpose of aiding you in such matters, We hereby appoint Our trusty and well-beloved John

White, Esquire, Barrister-at-Law, to be the Secretary to this Our Commission.

"Given at Our Court at *Saint James*, the thirtieth day of April, one thousand eight hundred and eighty-one, in the forty-fourth year of Our reign.

"By Her Majesty's Command,

"W. V. HARCOURT."

### The Small-Pox Epidemic.

THE forebodings to which we gave utterance some weeks ago in these pages, have been only too amply realised; and the greatest difficulty is being experienced in providing for the isolation of all who fall victims to the small-pox plague. So pressing has the need of largely increased accommodation become that suggestions to meet it are being daily made in the columns of the lay papers. It has been even recommended that Board-schools should be temporarily utilised as hospitaes, and subsequently, after complete disinfection, restored to their normal guardians. The author of this proposal exhibits the most charming ignorance of popular prejudices, by supposing for a moment that schools, once used for such a purpose, could ever again be successfully employed as educational centres of the young. And again, there is a strong objection, that perfect disinfection may not be carried out, thus presenting the risk of possible danger when the schools are once more used for their regular purposes. Certainly, the most feasible plan is that of erecting temporary premises for the reception of small-pox patients, who cannot be accommodated in the institutions specially set apart for such cases. There should be no hesitation in at once providing some arrangement of the kind; and whether of wood or of iron, their construction need be no considerable tax upon the resources of each threatened parish. Perhaps the best and most easily adopted temporary hospital is the tent, or marquee, an admirable pattern being made by Messrs. John Edgington and Co., of 48 Long Lane, West Smithfield. The cost of these is not great, and they can be erected, one by one, at an hour's notice, as the necessity for them arises. They are well adapted to meet the present emergency, and if placed in the outskirts away from immediate habitations no possible danger is to be apprehended; while the convenience they offer can hardly be over-estimated. This point of separation from dwelling places must, however, be insisted on; and the means of transit are as ready as to the more permanently-built hospitals. Every parish should be provided with a number of such temporary hospitals, for employment whenever, as in the present instance, the ordinary arrangements may be inadequate to meet the demands of isolation and treatment.

### The Vacant Coronership.

WE rejoice to be able to chronicle the fact that the contest for the office of Coroner for Central Middlesex, vacated by the decease of Dr. Hardwicke, was decided on Monday by an overwhelming majority in favour of the medical candidate, Dr. Danford Thomas, whose success is an important one to the profession of which he is a member. (The official declaration will be made to-day, Wednesday.) The controversy as to the re-

spective merits of doctors or lawyers as coroners, ill-sustained though it is by the lay organs of public opinion, has a grave bearing on the conduct of an important branch of the public service, and we feel that every one interested in the well-being of the medical profession will be glad of this recognition of Dr. Thomas's claim to an office for which he has been thoroughly well-trained during the period in which he has acted as deputy coroner. The appointment, moreover, is a highly valuable one, and such as there are few enough to reward medical men with.

### The "Doterel" Disaster.

THE terrible accident by which H.M.S. *Doterel* has been suddenly sent to the bottom of the sea, together with almost all on board of her, has deprived the medical profession of one of its most promising younger members. Staff-Surgeon Septimus Evans was among those destroyed in the ill-fated ship, and one who had given promise of achieving good work in the future. Mr. Evans became a member of the Royal College of Surgeons of England in 1877, and was also a Licentiate of the Apothecaries' Society of London. He leaves a widow and one child to mourn his loss, and will be long remembered by a large circle of friends who admired his professional instinct, and entertained for himself the most affectionate regards.

### The Davis Lectures.

THE series of Davis lectures for 1881 will be given at the Zoological Society's Lecture Room in the Gardens, and will commence on Thursday, June 16, at 5 p.m., continuing on successive Thursdays at the same hour. Prof. Flower, F.R.S., will deliver the first address on "Whales," and the following days will be filled up as follows:—June 23, "Dolphins," by Prof. Flower; June 30, "Extinct British Quadrupeds," by Mr. J. E. Harting; July 7, "The Limbs of Birds," by Prof. W. K. Parker, F.R.S.; July 14, "Birds, Ancient and Modern," by Mr. W. A. Forbes; July 21, "Zoological Gardens," by Dr. P. L. Solater, F.R.S.; July 28, "Chameleons," by Prof. Mivart, F.R.S., Fellow of the Society; and their friends are entitled to attend the lectures without payment, and visitors to the gardens will also be admitted free.

### The Homœopathic Verdict.

It was to be expected perhaps that the homœopaths would endeavour to make capital out of the recent publicity given to their association, but it must be confessed that in executing their resolve they have gone far beyond what would have been looked for by most persons who regarded them with curious expectation. *The organ of the homœopaths thus expresses itself in an article headed "Kidd, Quain, and Jenner."*—"Dr. Quain was also appealed to by Lord Barrington, and after a certain amount of hesitation, a written announcement from Dr. Kidd that he had not treated Lord Beaconsfield homœopathically—a statement which the unchecked progress of the noble Earl's illness testified to the truth of—that he would do for Lord Beaconsfield whatever Dr. Quain directed him to do, &c." The overpowering complacency of the non-scientific school is surely unparalleled; nothing but this,

the assumption that rational treatment hastened the termination, was wanting to prove the certainty that had been entertained, that, viz., the one aim of nonsensical practitioners is, and is only, self-advancement.

### Medical Society of London.

THE Medical Society of London held its annual conversation on Monday week last, when the session came to a close. The first proceeding was the delivery of an oration by Mr. Arthur Durham, who chose for his subject "The Surgery of the Future," and dealt with it in a thoroughly practical and admirable manner. He briefly reviewed the recent triumphs in abdominal surgery, and specially dealt with the topic of cancer from a surgical point of view. Following the delivery of the oration a number of musical performances took place, and a very enjoyable evening was spent by the fellows and their friends.

### International Medical Congress.

By the change in the Presidency of the College of Physicians, Sir W. Jenner becomes *ex officio* chairman of the General Committee of the Congress, a post the duties of which have, up to the present time, been so ably discharged by the late President of the College and Chairman of the Executive Committee, Sir Risdon Bennett. Owing to a deficiency in space for the accommodation of the sections dependent on the fact that the honours examinations of the London University will necessitate a portion of the buildings in Burlington Gardens being reserved, the Executive Committee have had to look for fresh meeting places, and these have been generously placed at their disposal by the authorities of the Royal School of Mines in Jermyn Street, and the Royal Institution in Albemarle Street, the use of the admirable theatres of both these buildings having been granted. Two hundred and fifty foreign medical men have up to this time definitely announced their intention to attend. Abstract papers are rapidly arriving for translation into the three official languages of the Congress. These will be regarded as strictly private communications until the opening of the Congress, when they will be published in connection with the programme already in circulation. Unless the abstracts are sent in early the translation and printing of them will become a sheer impracticability. The Committee have been much gratified by the receipt of fifty guineas, a liberal donation, from another corporate body, the Faculty of Physicians and Surgeons of Glasgow, thus raising the sum now received from such sources to £235, a very satisfactory proof of the favour and sympathy with which the Congress is regarded in the three kingdoms. The London medical corporations intend to show all the hospitality in their power. The College of Physicians have most liberally placed their house at the disposal of the Reception Committee for a head-quarters during the meeting, its central position making it especially desirable for such a purpose. The College of Surgeons will entertain the whole Congress at a conversation in the Hunterian Museum. The Society of Apothecaries purpose giving a dinner to a number of members in their hall at Blackfriars. The Executive Committee are

particularly anxious to make known to the profession that a register now lies at the College of Physicians, in the charge of Mr. Gurner, where members can inscribe their names and pay their membership subscriptions. The inscription of names in this book is particularly to be wished, since it will very much diminish the press of members who will need to be enrolled on the opening day of the Congress. At the College of Physicians also forms are provided to permit those desirous of offering hospitality to enter their own names and the names of the guests they wish to invite. An inspection of this book will prevent numerous invitations being sent to the same person for the same date, and will thus tend to distribute private hospitality more widely and evenly.

### Prescribing in English.

A BILL is now before the State of Pennsylvania with the following preamble:—"Whereas, grievous errors and mistakes have been made by druggists and others in the compounding of the prescriptions of physicians by reason of the same being heretofore written in the Latin language and in abbreviations thereof, as well as the quantities or proportions of the drugs or medicines being designated therein by figures or symbols in a mode not readily understood by the bulk of the people, whereby undue advantage and mystification of the patients may be taken by unscrupulous doctors, druggists, and persons who prescribe or compound medicines for the sick and poor, and, it being desirable to simplify the practice of medicine and to enable the public generally to better comprehend the names and nature of such drugs." All physicians and others prescribing, therefore, are, under a penalty of 20 dols., to be compelled to write the names and quantities in English, without abbreviations; and a copy of such prescription is to be affixed to the bottle or packet containing the medicine in question. All druggists, under a penalty of 10 dols., are to be compelled to conspicuously label, in unabbreviated English, everything they sell.

### The New Infirmary at Notting Hill.

THIS building is approaching completion, and will, in all probability, be opened officially at Midsummer to hold 600 sick poor belonging to the important metropolitan parish of St. Marylebone. Every modern improvement is introduced regarding sanitation; a staff of medical officers, superintendents, and nurses will be chosen by the Board of Guardians. The building is in blocks, and each block is so arranged as to have the benefit of what little sun is obtainable in winter. The idea we believe originated from a proposition of Dr. J. McGrigor Croft (one of the Guardians of St. Marylebone) who has taken great interest in the matter, and whose military medical experience in the arrangements of barracks and hospitals was of much service to the committee. The cost of this vast building will entail an expense of £120,000 to the ratepayers of this parish.

### Belladonna Liniment Poisoning.

SEVERAL cases of poisoning by belladonna liniment have recently occurred. In one of these, in which a wine glassful (ʒij. ʒij.) had been swallowed, recovery took

place on the administration of the physiological antidotes, pilocarpine and tincture of opium. Of the former 1-5th of a grain was subcutaneously injected every fifteen minutes, until 4-5ths of a grain had been used. It did not cause the least perspiration. These accidents seem to point to the necessity of adding, in a future edition of the Pharmacopœia, some well-known, powerfully odorous substance to the liniment, or of adopting some other means of readily distinguishing it from other medicines.

#### Morphia Antagonised by Atropia.

DR. JOY, of Michigan University, reports a case apparently moribund from morphia poisoning (seven and one-half grains having been taken), which recovered by the hypodermic injection of atropia. When he reached the patient with a solution of atropia sulph., he found him black in the face and not breathing. He immediately commenced artificial respiration, and injected five doses, of one-thirtieth of a grain each, during the next one and one-half hours. The effect was marked at the third dose, and before the last dose artificial respiration was unnecessary.

#### Dr. Steeven's Hospital, Dublin.

THE honorary appointment of consulting surgeon to Dr. Steeven's Hospital, rendered vacant by the death of the late Christopher Fleming, F.R.C.S.I., has been given to Mr. Porter, Senior Surgeon to the Meath Hospital and County Dublin Infirmary, and Surgeon in Ordinary to Her Majesty in Ireland. We congratulate the governors of this historic institution on the choice they have made. In the year 1861 Mr. Porter was appointed consulting surgeon to the Coombe Lying-in Hospital, and in 1876 he was elected to a similar position in St. Mark's Ophthalmic Hospital, whilst the University of Dublin, in recognition of his surgical attainments, conferred on him the degree of Master in Surgery (*honoris causa*). Since Mr. Porter's appointment as surgeon to the Meath Hospital he has devoted his attention to the clinical teaching and practice of surgery with great success, and has well deserved this new distinction which has been bestowed on him.

#### The Coroners (Ireland) Bill.

THE Select Committee on Mr. Healy's Bill has at length been nominated, and is as follows:—Mr. Law, Attorney-General for Ireland, Mr. Daly, Mr. Ewart, Mr. Healy, Mr. Blennerhassett, Mr. Robert Fowler, Mr. Litton, Mr. Richardson, and Mr. Tottenham.

The instruction to the Committee is "that they consider the operation of the law relating to coroners in Ireland, and, if they shall so think fit, to amend the Bill accordingly."

Seeing the great advantage from a thorough inquiry into the working of the inquest system in Ireland, Mr. Healy moved on Tuesday week to give the Committee power to "call for persons and papers," and otherwise to take evidence, but Mr. Law, on the part of Government, refused, and the Bill will accordingly be revised without

hearing *viva voce* testimony. The first meeting of the Committee has not yet been fixed, but as it is likely no time will be lost it behoves those who are interested in the subject to lay their views before the Committee without delay.

WE understand that Her Majesty the Queen has reappointed Mr. John Simon, F.R.S., and Mr. Pridgin Teale, F.R.C.S., to be members of the General Council of Medical Education and Registration of the United Kingdom for the ensuing five years.

THE office of professor-superintendent of the Brown Animal Sanatory Institution having become vacant by the resignation of Dr. Greenfield, applications are invited from candidates for the appointment. The salary is £300 per annum.

AT the annual collection for the Hospital Saturday Fund at Sheffield on Saturday week, the amount received was £924 4s. 4d., of which £846 3s. was subscribed by workmen, and £78 0s. 9d. collected in boxes in the streets. This is a falling off from last year of over £269.

AT the last examinations of the Royal College of Surgeons of England, of the 185 candidates 53 failed to satisfy the Board of Examiners, and were referred for three, and 3 candidates for six, months' further anatomical and physiological study.

By the election of Dr. Greenfield to a professorship in the University of Edinburgh, the office of professor-superintendent of the Brown Institution in London becomes vacant. The salary attached is £300 per annum, with opportunities for scientific research, and not overmuch work to perform.

OUR readers will have noticed that a considerable amount of malaria and diphtheria has existed in New York for some time past; the excitement has now reached such a pitch that, in some of the principal hotels and other prominent caravansaries, the stationary wash-stands and pipes have been removed from many rooms to avoid the possibility of sewer-gas contamination, the old-fashioned pitchers and basins being substituted.

In the principal foreign cities, the rates of mortality according to the most recent weekly returns, were:—Calcutta 34, Bombay 32; Paris 30; Geneva, 22; Brussels 26; Amsterdam 22, Rotterdam 25; The Hague 20; Copenhagen 23, Stockholm 29, Christiana 24; St. Petersburg 59; Berlin 24, Hamburg 26, Dresden 23, Breslau 26, Munich 40; Vienna 32; Buda-Pesth 40; Rome 27; Turin 25, Venice 22; Alexandria 34; New York 30, Brooklyn, 22, Philadelphia, 26, Baltimore, 23, per 1,000 of the population.

## Scotland.

(FROM OUR NORTHERN CORRESPONDENT.)

ANDERSON'S COLLEGE, GLASGOW.—OBSTETRIC CLASS.—Dr. Wallace, the newly-appointed lecturer, delivered the introductory address of his course on the 3rd inst. Mr. Sandeman occupied the chair. The lecturer was accompanied to the platform by Drs. Fergus, Grieve, the Rev. Dr. Marshall Lang, and several of his colleagues. In an interesting address, Dr. Wallace specially adverted to the important advances made in obstetrical science for the past thirty or forty years, instancing the introduction of anæsthetics, the signal success, in the apt hands of Keith, Spencer Wells, &c., of the operation for ovariotomy, and the treatments of flexions of the uterus. He humourously referred to the most recent obstetric fad, the honour of which Glasgow undoubtedly may claim, viz., the reception of the babe in a cloud of carbolic spray! In concluding, he paid the customary warm tribute to the memory and worth of his predecessor. With a little more practice in public speaking, and a little more care in pronunciation, Dr. Wallace promises to become an effective lecturer.

THE STRATHAVEN FASTING GIRL.—Scotland is not to be outdone even in the matter of prodigies; and Strathaven, notorious above all things for questions affecting the gentler sex, has recently produced its "Fasting Girl." In a report of this case, which appears in the *Lancet* of the 7th inst., Dr. James Dougal states "eighteen weeks ago last sabbath she took a small piece of fruit cake; since then her parents distinctly and firmly assert that no food of any description has been taken by her. She takes water freely, and occasionally sweets, but obstinately refuses to be tempted by even the pressing and kindly entreaties of her father." Dr. Dougal does not mention, unfortunately, the nature of the sweets taken; but as these are usually composed of flour, sugar, and aromatic material, if they are taken to any extent at all, the case can hardly be called one of absolute fasting. We are not surprised that patient's present condition is one of extreme emaciation. We shall be curious to hear more of this case.

FUNERAL HONOURS TO A MEDICAL MAN.—The obsequies of Dr. Rankin, of Airdrie, on the 3rd inst., show in how great respect he was held in the town of which he was medical officer and health officer. Notwithstanding the expressed wish of the deceased that his interment should be conducted in a strictly private manner, the inhabitants in their anxiety to do his remains honour gave what almost partook of the nature of a public funeral. First in procession to the New Monkland Churchyard came four policemen, with Superintendent Neilson as guard, and then followed the hearse, with twelve carriages of friends in rear. After these followed the burgh halberdiers in uniform, the Magistrates, Town Council, and other public bodies, being conveyed in six carriages in the rear. All along the route the shops were closed, and the town and church bells pealed in muffled tones.

THE HELENSBURGH SEWAGE QUESTION AND DR. HENDERSON'S EPIDEMIC.—The airy fabric of Dr. Henderson's scientific vision has ignominiously vanished under the investigation instituted by the local authority of this fashionable watering place. When Dr. Henderson's papers appeared in *The Glasgow Medical Journal* (a journal we believe still in existence), we were astounded at the dashing audacity of the deductions contained in them. They were quite typical

of the same logic which sustains the equally insane theories of milk and sewer-gas propagation of disease, and served possibly the same ends—ephemeral notoriety and spurious fame—much to the detriment of medicine as a science. We purpose adverting to this matter at greater length in our next impression.

GLASGOW ROYAL INFIRMARY.—Dr. David Foulis has been appointed Surgeon to the Glasgow Royal Infirmary Dispensary, *vice* Clark, promoted. Mr. Glaister has been appointed Lecturer on Medical Jurisprudence at the School, *vice* McEwen, appointed Lecturer on Surgery. Mr. Glaister is M.B. (Univ. Glas.) 1879. The prospects of the Royal Infirmary Medical School are brightening.

NATURAL HISTORY CLASS IN THE UNIVERSITY OF EDINBURGH.—We understand that, in consequence of the continued indisposition of Sir Wyville Thompson, the Natural History Class in the Edinburgh University will be conducted during the summer session by Dr. Alleyne Nicholson, who also undertook the duties of interim professor last summer.

THE DEATH-RATE OF GLASGOW.—The deaths in Glasgow for the week ending with Saturday, the 30th ult., were at the rate of 22 per 1,000 of the population on the census enumeration, as compared with 22 in the previous week and 23 in the one immediately preceding. In the corresponding weeks of 1880, 1879, and 1878 the figures were 22, 21, and 28 respectively.

LAZY STUDENTS.—The Senatus of the Edinburgh University, at a meeting held on the 2nd inst., rusticated two students—one in arts, and the other in medicine—for copying or using notes at the recent degree examination.

THE CHAIR OF PATHOLOGY IN THE UNIVERSITY OF EDINBURGH.—At a special meeting of the Senatus of the University of Edinburgh, held on the 2nd inst., Dr. Greenfield, of London, was formally inducted to the Chair of Pathology, to which he was recently appointed by the Curators.

REOPENING OF THE EDINBURGH UNIVERSITY MEDICAL CLASSES.—The medical classes in connection with the University of Edinburgh, were opened for the summer session on the 2nd inst. A large number of students have been enrolled.

---

## Literature.

### AIDS TO THE CHEMISTRY AND TESTS OF THE PHARMACOPŒIA. (a)

THE first part of this little work is rather cleverly arranged, and most of the definitions and descriptions of the laws of chemistry are concise and to the point. There are, however, some which cannot be called strictly correct. The author has also the gift of being able to skim with good effect the surface of the instructive books named in his preface. He has taken up all the most salient points of the theory of his science well, but if any proof were required of the desirability of extending the practical part of examinations, we need look no further than the book before us. If such "aids" are sufficient for the student who is going up for his examination, so much the worse for the profession. We will pass over such funny equations as  $KClO_3 + \text{heat} = KCl + O_2$ , or  $S + \text{heat} = SO_2$ , but must protest against the unsystematic manner in which the testing of the pharmacopœia is placed before the student, and the impractical

(a) "Aids to the Chemistry and Tests of the Pharmacopœia." By James Davison, L.R.C.S.I., L.K.Q.C.P.I. Fannin and Co., Dublin.

selections made as regards the special tests. Besides, the general loose manner in which this part of the book is written is most objectionable. For instance, we find "alumen" given as a metal, and the student is left to find out by his own acumen the difference.

#### A GERMAN-ENGLISH MEDICAL DICTIONARY. (a)

At the present time it is essential for every medical man who wishes to keep up with the medical literature of the day to be able to read German works and journals. Unfortunately years ago the study of German in our schools was not so general as it now is, and therefore many of the present generation of doctors are ignorant of the language. Some, with commendable energy, set to work to remedy the defect, and learn to read the language; but they are soon met by a difficulty, viz., the frequent occurrence of technical terms which they are unable to find in the ordinary dictionaries. Dr. Barnes has set himself to provide a means of overcoming this difficulty, and very ably has he done the work. He has included most of the technical words used in botany, chemistry, zoology, anatomy, physiology, medicine, midwifery, and surgery.

The difficulties of compilation of such a book must have been many, by no means the least of them being, as Dr. Barnes says in his preface, "the collection of the ever-multiplying legion of new words." We know how peculiarly fond the Germans are of coining new words and new combinations of words, and it is evidently impossible for a dictionary writer to grapple with this propensity. We have personally made use of Dr. Barnes's work, and have not found it fail us, and we can therefore conscientiously recommend it to those in want of such an aid.

A word must also be said for the manner in which the work is got up. The type used is well adapted for the purpose, and the printing and binding are unexceptionable.

Dr. Barnes's work is an acquisition and an indispensable companion to all who study German medical literature.

### Medico-Parliamentary.

#### HOUSE OF COMMONS.—MAY 5TH.

##### SMALL-POX.

IN answer to Baron H. de Worms, Mr. Dodson said the Local Government Board had been pressing upon guardians, vestries, and district boards the necessity of supplementing the accommodation for small-pox patients which was at the disposal of the Asylums Board, and he was happy to say that in several cases effect had been given to the Board's representations. At the same time he was quite sensible of the urgent necessity for further accommodation for the isolation of such cases; the Board were earnestly endeavouring to procure it.—Mr. Dawson asked whether arrangements had been made for convalescent homes to receive patients who came out of hospital at a dangerous stage.—Mr. Dodson said no steps had been taken in that direction.—Mr. Dawson gave notice to call attention to the subject.

##### THE CONTAGIOUS DISEASES ACTS.

IN reply to Mr. Hopwood, Sir W. Harcourt said it was true that a girl, named Elizabeth Burley recently threw herself into Dover Harbour through fear of the police officer appointed to carry out these Acts at Dover. The police seemed to have showed great want of discretion and judgment in making their inquiries, and they had accordingly been reprimanded. The girl was promptly rescued from the water, and there was reason to believe that, owing to the attention which had been drawn to the case,

(a) "A German-English Dictionary of Words and Terms used in Medicine and its Cognate Sciences." By Fancourt Barnes, M.D., M.R.C.P., Physician to the British Lying-in Hospital, &c., &c. London: H. K. Lewis, Gower Street, W.C. 1881.

the girl had been saved from the unhappy life which she had been leading.

##### OLEOMARGARINE, BUTTERINE, ETC.

Mr. Dodson, in answer to Mr. Severne, said numerous convictions had taken place for selling these articles as butter. District inspectors received their instructions from the local authorities, but it was open to any private person to procure samples of suspected adulterations.

##### MAY 6TH.

##### SMALL-POX TENTS.

Replying to Colonel Makins, Mr. Dodson stated that the small-pox tents in the Imperial Road, Fulham, were near the Imperial Gas Company's Works, and the Fulham Waterworks; but to no other buildings whatever.

Colonel Makins gave notice to ask whether application had been made by the Asylums Board for permission to erect a temporary hospital at Wormwood Scrubs; whether the application had been refused, and, if so, on what grounds?

## Correspondence.

#### NEW SCHEME OF EDUCATION AND EXAMINATION OF THE ROYAL COLLEGE OF SURGEONS, IRELAND.

##### TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The Council of the Royal College of Surgeons in Ireland having, at their meeting on Thursday last, finally adopted the Report of the Education Committee recommending a new scheme of education and examination, it is right that the Fellows of the College and the profession at large should be made acquainted with it and its objects.

The scheme has been referred back to the Committee to be put into the form of a code of regulations, and to have the details filled up, when it must again come before the Council previous to its being put into operation. That it should meet with opposition at this stage is not improbable, for it is calculated to remove abuses, and perhaps injure the pecuniary interests of some, and to introduce reforms that may alarm the timid and shortsighted. Under these circumstances I beg to be allowed to relate its history and make some comments on its provisions.

Some two years ago the General Medical Council forwarded to the several licensing bodies in the three kingdoms a series of recommendations for the improvement of the education and examination of students. These recommendations had reference, in the first place, to the enforcement of a full period of four years study. Secondly, to the improvement of the preliminary education of students, urging that they should be encouraged to prosecute the study of the natural sciences before they engage in studies of a strictly professional character. Thirdly, to the improvement of the professional education, making it more practical, and less theoretical.

The Council of the College, desirous that the Irish College should, as ever, hold the first place in the advancement of professional interests, applied themselves earnestly to the consideration of these recommendations, and, as a first step, adopted on the 20th December, 1879, those intended to enforce the four years study.

Hitherto students had been able, by ingenious adaptations of the regulations of the Irish, as well as of the other colleges, to obtain their diplomas at the end of a period of actual study extending over not more than two years and nine months, or even two years and six months. Moreover, those who were idly inclined, were able, by the aid of skilful "grinders," to cram all their preparations for examination into the latter months, devoting the remainder of their period of nominal study to idleness and pursuits not calculated to improve their moral or professional reputation. On a careful examination of the recommendations of the General Medical Council, it became evident that the same course of nominal study—idling and cramming—could be pursued with impunity under their provisions,

and that to carry out the object, and to make the education of the student more thorough and practical, a further reform of the system was necessary. With this view, and after consultation with some members of the Council, an outline of a new scheme of education and examination was prepared and laid before the Council on the 7th July last, and was by them referred to the Education Committee. The Committee elaborated and worked out the scheme, devoting thirteen meetings, many of them extending over several hours, to its consideration, and sent it up in an improved form, recommending its adoption; and the Council of the College have, after most careful consideration, and devoting numerous meetings to its examination, adopted it with further amendments; and it is to be hoped it will now without much further delay become the law of the College. It is to the scheme as elaborated that I desire to direct the attention of your readers, believing it all important for its working that it should have their assistance and hearty co-operation.

In another letter I shall, with your permission, enter into an examination of the clauses of the scheme.

Yours faithfully,  
GEORGE H. KIDD.

\* \* \* We shall publish the amended scheme referred to by our correspondent in our next.—Ed.

#### THE DATE OF ANNUAL MEETING OF THE IRISH COLLEGE OF SURGEONS.

THE meeting of the Fellows of the College, at which the Council presents its annual report, has hitherto been held on the last Monday in May, being the day week preceding the meeting for election of Council and officers, and as this has been found very inconvenient for provincial Fellows, who could hardly be expected to make two journeys to Dublin with an interval of a week between, it has been decided to change the day of the report meeting. This alteration was recommended to the Council by the meeting of Fellows last year, and a plebiscite has, since then, been taken by the Council, the result of which was an overwhelming majority for the change, which therefore, we believe, will be carried into effect. We hope the new arrangement will induce the provincial Fellows to come to Dublin in larger numbers than usual this year. It will be possible for them, henceforth, to be present at the general meeting of the College on Saturday, enjoy private hospitalities on Saturday evening and Sunday, partake of the annual breakfast of the Irish Medical Association on Monday morning, attend the election at the College, and the annual meetings of the Irish Medical Association and the Royal Medical Benevolent Fund Society, wind up the day with the dinner of the Association, and return home by the night mail trains or by the early trains on Tuesday.

It is greatly to be desired that the profession throughout Ireland should make an effort to be present at this yearly gathering, and we hail with satisfaction the new arrangements which afford them facilities for attending.

#### POOR-LAW MEDICAL OFFICERS' COMPULSORY SUPERANNUATION.

MR. DODSON, President of the Local Government Board, having consented to receive a deputation from the Poor-law Medical Officers' Association on the subject of compulsory superannuation, has fixed Tuesday, the 17th inst., at 2 p.m. precisely, at the Board's Offices, Whitehall. It is earnestly hoped that all Poor-law medical officers and others interested in this question will make an effort to attend, and that they will use what influence they possess to induce such M.P.s as they may happen to know to be present in support of the object of the Association.

## Obituary.

### DR. R. WILBRAHAM FALCONER, OF BATH.

THE very sudden death of this gentleman, who for many years has occupied a prominent position as consulting physician at Bath, for many years Treasurer, and in 1878 President of the British Medical Association has cast quite a gloom over the old "city of waters." So recently as Thursday last, says the *Bath Herald*, he might have been seen driving through the streets on his professional rounds with no trace of disease palpable to the casual observer. But before he had finished seeing the whole of his patients, he stopped at his club exhausted, where he remained for a short time before proceeding to his residence in Bennett Street, which he never again left. Here the prostration increased despite the best medical skill, which was immediately summoned to his aid, and at half-past seven on Friday evening death ensued from syncope, coupled with congestion of the lungs, at the age of 65.

Dr. Falconer inherited a name which for more than a century has been honourably distinguished both in the medical profession and the paths of literature. His grandfather, Dr. W. Falconer, the *Bath Herald* states, was the son of the Recorder of Chester, and came to Bath in 1770, where he practised as a physician. His son was the Rev. Thomas Falconer, who became a Fellow of Oxford in 1794, and entered Holy Orders. He was an accomplished scholar, and subsequently he took at the same University the M.D. degree and practised medicine, besides officiating as curate at St. James's Church. He left five sons and two daughters, the youngest son being Dr. R. W. Falconer, the subject of this memoir. Like his father before him, he attended the medical classes at Edinburgh, and received the degree of M.D. in 1839, commencing his professional career at Tenby, where he remained for several years; but preferring his native city he returned to Bath in 1847, where he soon acquired a prominent position, both in his profession and as a citizen.

Anxious for the reputation of the city, he was a zealous advocate of sanitary reforms, but interested himself particularly in maintaining the prestige of its mineral springs, in connection with which he wrote one or two works, the chief being entitled "The Baths and Mineral Waters of Bath." For many years down to his decease he was the senior physician to, and subsequently president of, the Mineral Water Hospital, besides being consulting physician at the Royal United Hospital. In 1857 he served the office of Mayor of Bath, and was unanimously re-elected the following year in testimony of the esteem in which he was held by his fellow townsmen. Dr. Falconer was also a Justice of the Peace, besides filling many other posts of honour at the time of his decease. He was a F.R.C.P. Lond., M.D. Q.U.I., M.D. Ed., F.K.Q.C.P.I., and D.C.L. Durham.

University of Cambridge.—At a court holden Thursday, May 5th, the following obtained the degree of Bachelor of Medicine:—

John Mackern, Caius College; Herbert George Cronk, Jesus College.

Royal College of Surgeons in Ireland.—At a meeting of the College held on Monday, May 2nd, the following were elected examiners for the ensuing year:—Examiners for the Letters Testimonial and Fellowship: Henry Gray Croly, William Frazer, Benjamin G. McDowell, Edward Stamer O'Grady, Benjamin Wills Richardson, Edward A. Stoker, Robert S. Swan, and Wm. Thomson. Examiners in Midwifery: John J. Cranny, Henry Croly, and William J. Smyly. Examiners in General Education: Michael Joseph Malone, Robert Morton, and Henry Tweedy.

University of Aberdeen.—At a meeting of the University Court on April 22nd, the degree of M.D. of this University was conferred on the following gentlemen:—

Frederick Theobald Keyt  
Alfred Henry Burton, M.B., C.M.  
John Kerr Butter, M.B., C.M.  
Alexander Bruce Cheves, M.B.  
Harry Edward Dixey, M.B., C.M.  
Ernest Field, M.B., C.M.  
Andrew Fowler, M.B., C.M.  
Donald Manson Fraser, M.B.  
Henage Gibbes, M.B., C.M.  
Giles Forward Goldsborough, M.B.

Douglas Dent Malpas, M.B.  
William Mearns, M.B., C.M.  
James Noble, M.B., C.M.  
Andrew Norrie, M.B., C.M.  
Thomas Wade Richards, M.B.  
George Jolly Shand, M.B., C.M.  
Frederick Henry Spooner, M.B.  
Winckworth Tonge-Smith, M.B.  
Herbert Redwood Vachell, M.B.  
Augustus Desiré Waller, M.B.

The degrees of M.B. and C.M. were conferred on the following:—

William Allardes  
William Milne Anderson  
William Cooper  
John Cowie  
Alexander Dey  
James Duffus  
George Powell Doyle  
David Duncan  
Robert Hume Fallon  
Charles Andrew Ironside, M.A.  
James Lawson, M.A.  
Frederick William Lerew  
James Leith Leslie  
Thomas Marsden

Harrie Michie  
James Gowing Middleton  
James Millar  
David George Prothero  
Charles Boards Richardson  
James Bernhardt Klingner Robb,  
M.A.  
Edward Wagstaff Robertson  
Hermann Rogers-Tillstone  
George Shires  
Dyne Steel  
William Wilfred Webb  
John Alexander Williams.

**University of Durham.**—At the First Examination for the degree of Bachelor in Medicine, concluded on Friday, April 29th, the following candidates satisfied the Examiners:—

Austen, Henry Hinds, M.R.C.S.  
Beasley, William Crump  
Brown, Arthur Trecco Franklyn  
Brown Richard  
Cock, Frederick W.  
Dowdney, George Herbert  
Hardie, Robert  
Hepworth, Arthur  
Howitt, George Grahamsley  
Hudson, Theo. Joseph, L.R.C.P.,  
M.R.C.S.  
Hutchinson, Joseph Armstrong.  
Lingard, Alfred, M.R.C.S., L.S.A.  
Morgan, Llewellyn Arthur  
Norry, William Anagnatus  
Paley, Wm. Edm'd, F.R.C.S. Eng.

Price, William Elliott  
Prowle, Edwin Longstaff, M.A.  
Cantab.  
Ridley, George Walter  
Selvage, John Valentine  
Shuter, Charles Yalden  
Spencer, Frederick  
Tomson, Walter Bolton  
Turnbull, William  
Triay, Abelardo Joseph, B.A.,  
L.M. & S.  
Vise, Christopher, M.R.C.S.  
Walker, Basil Woodd, L.R.C.P.,  
M.R.C.S.  
Wigan, Charles Arthur

Thirty-eight candidates entered for the examinations, two withdrew, and nine were referred to their studies for a period of six months.

## NOTICES TO CORRESPONDENTS.

**DR. EDWARDS.** By all means forward the MS., but we make no promise about it other than to carefully consider it.

**F.R.C.S. (Cambridge).**—Your views on circumcision and Christianity are somewhat confused. When sending communications to this Journal your card should be enclosed, not necessarily for publication but as evidence of good faith.

**DISPENSARY DOCTORS AS CORONERS.**—W. M. asks if the Irish Local Government Board will permit a dispensary doctor to hold in addition the office of coroner for the same county, and what is the law in the matter?

[There is no law to prevent a dispensary medical officer holding the coronership, but the Irish Local Government Board does not approve of the arrangement, and will not sanction the appointment of a coroner to a dispensary, but it cannot prevent the appointment of a dispensary doctor to be coroner, nor dismiss him if so appointed.]

**SILEX.**—The principal substances used in the fitting of fixed bandages are, plaster of Paris (sulphate of calcium), silicates, and a compound of shellac and plaster. It has been suggested that for limbs a good jacket might be made from ground coke and shellac, but we have not seen it tried.

**ALPHA.**—Not at all. There were only three present, and of them two were incapacitated by age from joining in the exercise. Perhaps in about two months' time we shall be able to reply more satisfactorily. Apply again then.

**DR. BRUCE.**—Letter received as we were at press, will appear in our next.

**DR. CULLIMORE (London).**—Communication received, will appear as soon as space permits.

### THE NOTIFICATION OF INFECTIOUS DISEASE IN IRELAND.

It was said in the House of Commons by Mr. Gray in his speech on the second reading of his Bill, that all the representative medical organisations in Ireland were in favour of the measure, a statement which—as we have already pointed out—was entirely contrary to the facts, inasmuch as not one single medical body in Ireland, collegiate or other, had approved of Mr. Gray's propositions. We have already published the condemnatory resolutions of the Irish Medical Association and of the North of Ireland Branch of the British Medical Association, and we have reason to believe that the decisions arrived at by the Irish College of Physicians and the Dublin Branch of the British Medical Association were also hostile to the method of notification proposed by Mr. Gray. There only remains, then, the verdict of the Council of the Irish College of Surgeons to make complete and unanimous the disapproval of the Bill by the medical profession in Ireland, and, to put the nature of this verdict beyond doubt, we publish below the resolutions arrived at by the Council of the College:—

*Resolved, July 15, 1880.*—That the following report of the Parliamentary committee be received and adopted: "That the Council be recommended to state in reply to the letter of the Hon. Sec. of the Dublin Branch of the British Medical Association that the College fully recognises the great desirability of registration of infectious diseases, and would approve of any measure which would make efficient provision for such registration *without interfering with the confidential relation of the physician to his patient, or imposing upon him a*

*responsibility inconsistent with his professional practice.* That the College considers that in any legislative proposition the onus of reporting to the sanitary authority ought to devolve upon the responsible occupier of the house in which the disease occurs."

Subsequently, on the approach of the second reading of the Bill, it was furthermore resolved—

"That the Council of the College, while approving of the principle of the notification of infectious diseases, are of opinion that the Bill should be referred to a Select Committee with a view to removing certain objections to the details of the Bill."

**J. S. C.**—The character of the spots is, from your description, unmistakable to us, and taken with the previous history of the case, makes its nature abundantly clear. Under the circumstances we would advise you to withdraw from the treatment, as where by agreement between consultants is impossible, no benefit to any one concerned will result from the association. The adverse opinion should have been expressed to you alone; by informing the friends that your diagnosis was different from his, coupled as it was with invidious remarks, the consultant was guilty of a grave breach of etiquette. We should be glad to see the letters of justification.

**A SECOND YEARS' MAN** cannot do better than to get Harris and Power's little manual for the "Physiological Laboratory," Hentfrey's "Small Botany," and Griffith's "Materia Medica."

**DUBIOUS.**—Read "Fasting and Feeding Psychologically Considered."

**HONORARY SECRETARY.**—You need not trouble to send us any more touting circulars, we shall not again place you in such good company by mentioning your name.

**HABITUAL DRUNKARD.**—A meeting is to be held in London on Tuesday next at the Mansion House, under the presidency of the Lord Mayor, for the purpose of promoting the establishment of a model retreat for the care and treatment of inebriates. The meeting is open to the public, and the chair will be taken at 3 p.m.

**ROYAL INSTITUTION.**—Thursday, May 12, at 3 p.m., Prof. Tyndall, "On Magnetism."

**OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.**—Thursday, May 12, at 8.30 p.m., Mr. Spencer Watson, "On a Case of Retinal Hemorrhage, with High Arterial Tension."—Dr. Allen Sturge, "On Paralysis of both Third Nerves after an Apoplectic Attack."—Mr. Jas. E. Adams, "On Embolism of Both Eyes in a Case of Endocarditis."—Mr. Lang, "On Optic Neuritis in a Case of Corneal Ulcer (microscopical sections)."—Living Specimens at 8 p.m. Mr. Brudenell Carter, "On a Case showing the result of previous Neuritis from Injury to the Head."—Mr. McHardy, "On Persistent Hyaloid Artery."—Mr. Nettleship, (1) "On Dislocation of Lens between Choroid and Sclerotic;" (2) "Ophthalmoplegia Externa;" (3) "Card Specimen of Tumour at Cavernous Sinus, causing Uncomplicated Ophthalmoplegia."

**ROYAL INSTITUTION.**—Friday, May 13, at 9 p.m., Mr. F. Galton, "On Mental Images and Vision."

**CLINICAL SOCIETY OF LONDON.**—Friday, May 13, at 8.30 p.m. Report of the Committee on Excision of the Hip-joint.—Dr. Whiphram, "On a Case of Aneurism of the Aorta, demonstrated during life by the Laryngoscope."—Dr. T. Stretch Dowse, "On a Case of Anorexia Nervosa."—Mr. A. P. Gould, "On a Case of Rapid Death after Antiseptic Osteotomy of the Tibia."—Dr. Wiltshire, "On a Case of Traumatic Rupture of an Ovarian Cyst."

## APPOINTMENTS.

**AVERILL, A.**, M.R.C.S.E., Medical Officer to the Cavenswall District of the Cheadle Union.  
**BOWIE, A.**, L.R.C.P.Ed., L.R.C.S.Ed., Resident Surgeon to the Royal Maternity Hospital, Edinburgh.  
**BREW, Dr. H. B.**, Medical Officer for the Bray (co. Dublin) Dispensary District.  
**CLARK, H. E.**, L.R.C.S.Ed., L.F.F.S.G., M.R.C.S.E., Surgeon to the Glasgow Royal Infirmary.  
**HAMILTON, A.**, F.R.C.S.Ed., L.R.C.P.Ed., Hon. Surgeon to the Chester General Infirmary.  
**HARVEY, A.**, M.B., Surgeon to the Hockley Provident Dispensary, Birmingham.  
**KEILLER, A.**, M.D., F.R.C.P.Ed., F.R.C.S.E., Acting Physician to the Royal Maternity Hospital, Edinburgh.  
**LIVETT, H. W.**, L.R.C.P.Ed., M.R.C.S.E., Medical Officer of Health for the Wells Urban Sanitary District.

## Births.

**FIRTH.**—May 3, at St. Giles Street, Norwich, the wife of Chas. Firth, F.R.C.S., of a daughter.  
**MCCARTHY.**—May 1, at Bridgmont, Abbeyleale, the wife of John P. McCarthy, M.D., of a daughter.  
**WRIGHT.**—May 2, at 17 Alexandra Road, Southport, the wife of S. H. Wright, M.D. Ed., of a son.

## Marriages.

**BOSS-M'CLOGHRY.**—April 28, at St. John's Church, Sligo, William Ross, M.D., to Frances Elizabeth, eldest surviving daughter of the late Henry M'Cloghry, Esq., of Riverstown, co. Sligo.

## Deaths.

**DAVIES.**—April 21, at The Poplars, Oswestry, John Sides Davies, M.R.C.S.E., aged 44.  
**HALL.**—May 2, at Ladbroke Road, Bayswater, Nathaniel Francis Hall, M.R.C.S., aged 47.  
**NOYES.**—May 2, at Brandram Road, Lee, Kent, Henry George Noyes, M.D., in his 64th year.  
**SIMPSON.**—April 24, William Simpson, M.R.C.S.E., of Bradmore House, Hammersmith, aged 78.  
**SMITH.**—May 3, at St. Mary Cray, Kent, Thomas Heckstall Smith, F.R.C.S., aged 74.

### ON THE NEGLECT OF LOCAL AND GENERAL BLEEDING.

By T. M. DOLAN, F.R.C.S. ED., L.R.C.P. ED.;  
Medical Officer, Halifax Union Infirmary.

VENESECTON is now almost a forgotten remedy, and cupping glasses are rarely seen. The last of the cuppers, Mapleson, of Dublin, called on me a few years ago to take tickets for some readings he was about to give in this town, and he pathetically remarked that "his occupation, like Othello's, was gone." Leeches are even now at a discount.

Amongst the younger members of the profession there are some who never even saw venesection performed, and in that number I was reckoned, until, in the course of my reading, I came across the Gulstonian lectures of Dr. Markham. I was so struck by the lucidity of his views, his logical arguments, sound deductions, and physiological facts, that I was tempted to examine the subject practically and theoretically; when I had tested its efficacy, and weighed in the scale of thought the arguments *pro* and *con*, I was converted to his opinion, that blood-letting does not hold at the present time its proper position as a therapeutical agent, and so far the interests of our patients are prejudiced.

I would be far from advocating its indiscriminate use, or a return to those dark ages of medicine, when everyone was bled, in health and disease, when the physician reckoned his successes by the number of gallons of blood he had abstracted. As we pass along the streets at the present time, we have a reminiscence of the sanguinary epoch of medicine, in the variegated pole of the barber, representing the blood, bandages, and staff used during the operation. In the course of my remarks I will briefly state the class of cases in which bleeding, local and general, may with propriety be adopted, founded on the more advanced views of the pathology and physiology of the present day.

In the progress of society we find certain periods when

revolutions spring up, in politics, religion, and science; when extremes are rushed into and men yielding to the wave of public opinion follow the most extreme leader; of which fact in politics, the French revolution furnishes us a notable example with all its train of horrible consequences. It was followed by a reaction until ultimately a happy mean was arrived at. Medicine has passed through such changes, of which the anti-blood letting mania is one of the most prominent. Such revolutions, though extreme, are productive of some good; formerly we had indiscriminate bleeding, then no bleeding; now, when the first heat of the reaction has cooled, the time has arrived when we may dispassionately reconsider both sides.

In the brief outline which I venture to lay before the profession of the cause of the change, and the effects of blood letting in certain affections, we shall see that there is something to be gained by a modified form of bleeding.

Dr. Markham, in his lectures, set himself the task to trace the progress of this change, to show how blood-letting, after being sanctioned by antiquity and by names high up in the fame roll of medicine, was first tabooed; how the cry was taken up by the metropolitan schools; how it was thundered out from the professorial chairs; how it was eschewed in the provinces, until the non-medical public joined in the chorus. Though the subject may seem, superficially, one of not sufficient importance for consideration, yet, if we look at it closely, we shall find in it much interesting matter for discussion, and this must be my excuse for reviving the topic at the present time.

We are first naturally struck by this question—Why men ceased to bleed? We have heard, in the medical and non-medical world, much of a change of type in disease, in a gradual deterioration in the human family, whereby patients could not bear the exhaustion of blood; in consequence of this it was supposed that the practice of bleeding was discontinued.

This change of type or asthenic phase of disease is presumed to have set in about the year 1823, though its discovery and the term applied, only bear date 1857. We may briefly look at the grounds on which this change of type theory is based. It is founded on the assumption that the effects of blood-letting now are different to what they

were in former times, so that we have to make an estimation of blood letting at different and distant periods of time. We have to satisfy ourselves that the remedy which was a good one, in the hands of our fathers, is a bad one now.

Such an investigation is surrounded by many and grave difficulties, and the first that will strike us is the difference between the practice, the therapeutics, and the diagnosis of the practitioners of a former time, and those of the present day. If we look at the treatment of fever by bleeding, we shall find that, before any extreme wave had set in or was even thought about, thoughtful physicians were observing its effects and arguing on its *rationale*. Amongst them I must mention the name of Graves. Fever in his day, 1827, was treated on the depletory plan; the floors of the Meath hospital ran with blood from phlebotomised patients. But we find at that time Graves was questioning the judiciousness of the treatment, and was pointing out to his class not the necessity of depletion, but showing them that nourishment was necessary. To Graves belongs the credit of introducing into the Irish schools of medicine clinical instruction, and a rational system of medicine founded on pure physiology. I am told that the visitor to Glasnevin cemetery will find on his tombstone, to commemorate his change of treatment the following words:—GRAVES FED FEVER.

His conversion was not brought about by any change of type theory.

This change of type theory is not supported by the records of parturient women, who bear the enormous loss of blood they sustain in post-partum hæmorrhage as well now as they did formerly. Nor by the surgeon is it complained that the great loss of blood during operations is worse in its effect now than formerly; whilst the practitioners, who still largely bleed in fever, maintain that loss of blood is as well sustained now as ever it was. We find then, without having recourse to a change of type theory, that venesection was abandoned, not from a deterioration of the human family, but owing to the strides which medicine was making; owing to the researches of Prout, Majendie, Bernard, &c.; from improved scientific knowledge. Modern pathology was showing that venesection never could have been a proper remedy in fever, acute rheumatism, tuberculosis, &c., &c. This brief glance at this change of type theory is essential to a proper understanding of our subject; for if we have an æsthetic wave or believe in it, few will bleed even with leeches or cupping glass: disabuse our minds of this idea and we can again have recourse to the lancet, not blindly or because it is the fashion, but in accordance with the light of modern rational scientific medicine.

We have again in estimating the value of blood-letting to consider the following points,—viz., the direct and indirect abstraction of blood, the one being local, the other general. Take, for instance, an inflamed part visible to the naked eye, an inflamed ankle-joint, or conjunctiva; general blood letting would be, in such a case, useless, but if we apply leeches round it relief is obtained, and an excellent influence over the progress of the inflammation is established; the heat, the redness, the swelling, and the pain subside. Now the *rationale* is as follows:—By the leeches a certain quantity of blood is drawn from the part, the congested vessels are relieved, the contractility of the vessels is enabled to be kept in action to complete resolution. By venesection, or general bleeding in such cases, no good result would be obtained, its effect would only be transmitted through the general circulation, and the influence over the inflamed part would be only in the same ratio to that exercised over all other parts of the body, the main influence being a reduction of the heart's power. The amount of blood drawn from the body would be equal in all parts, and that from the ankle-joint would probably not be as much as that extracted by a single leech.

In the case of external inflammation, we use leeches, cupping; there the effects are visible and patent to the eye. Next comes the question of bleeding in internal inflammation. What is true of inflammation ex-

ternally, must be equally true of inflammation internally. If, for example, venesection has no directly beneficial influence over an inflamed ankle, neither can it have any direct influence over an inflamed peritoneum, and so, if the direct abstraction of blood be beneficial in the case of external inflammations, equally beneficial should it be in internal inflammations, if capable of being practised. We have, however, a useful example of venesection in those cases where the play of the organs of respiration and circulation are interfered with, as in pneumonia, and the bleeding is a secondary operation relieving, not the inflammation, but its results.

Bleeding has been highly lauded in pneumonia, where we have great difficulty of breathing, and where the obstruction is marked and is sudden; even while the blood is flowing we find the patient is relieved, but here the relief is of a mechanical character. When pneumonia entirely pervades a lung suddenly, a large aerating surface is rendered useless, and there is an undue relation between the mass of blood and the aerating surface; the lung is doing the work of two, the blood is obstructed in its passage to the lungs, and the right side of the heart is engorged. Engorgement gives rise to loss of the natural force of the heart's power. By bleeding, the heart is enabled to take on fresh action, while the lung is secondarily relieved. In cases of pneumonia, where respiration and circulation are not interfered with, bleeding has been ignored. In the local abstraction of blood in internal inflammations, the same facts hold good as in external. Where we have a vascular connection between the skin and the inflamed part, this influence is seen, as in pleuritis and pericarditis. In the latter affection the removal of the pain may result from the direct abstraction of blood from the pleura, local pleurisy being an almost invariable associate of pericarditis; a branch of the internal mammary artery, which supplies the skin and intercostal arteries, over the præcordial region, is distributed to the pericardium, forming a direct vascular connection between the skin and pericardium.

Leeches, likewise, give relief in pericarditis, and for a similar reason. Leeches, again, give relief in affections of the liver, and after death, we find extensive adhesion between the anterior surface of the liver, and the parietal layer of the peritoneum.

Now, in cases where leeches are applied over a part with which it has no vascular connection, we have no specific or peculiar influence, although so near the seat of inflammation, and the abstraction of blood can only act as venesection would—that, is through the general circulation. Brown-Séquard and Claude Bernard suggest, that any good effects by leeches over internal inflammations—in which there is no capillary communication between the skin and inflamed part—may be ascribed to the excitement of reflex action of the motor nerves of the part, producing contraction of the inflamed capillaries. If there is not such an action it is difficult to account for the beneficial influence of blisters and plaisters over the lungs. We know, empirically, they give relief.

Speaking of motor nerves, it may be alleged, now that we have a vaso-motor theory, that we have medicines which will control the circulation, increasing or diminishing the calibre of blood vessels, producing arterial tension or dilatation; that it must be better to resort to such drugs than abstract any of that fluid, on which life so much depends. Thus, aconite is most useful in pneumonia, it relieves the pain and tension, and does so by vaso-motor action. But though, valuable in the early stages of vascular excitement it cannot act, as venesection would, by relieving the mechanical disturbance of the blood so often existing in pneumonia; nor has it any beneficial action in the secondary results too often found attending this disease. Again, its effects are not so speedily or surely produced in other affections, say cerebral diseases; the local application of ten or a dozen leeches will give more direct and speedy relief than can be obtained from any medicines, however specific, or noted

for their action on disturbed intra-cranium circulation.

I could narrate a number of cases where relief has been given by local bleeding. I give one item amongst many, where the effect was most marked.

Margaret Dale, æt. 17, had been under my care for 8 or 9 days, for typhoid fever; and on the 10th I found her complaining of internal pain in the side, with considerable difficulty of breathing, arising from inflammation of the pleura, pulse being 110, temperature high. I advised the application of 10 leeches with other appropriate treatment; on calling next day, the pulse had become soft, the breathing had become calm, and the pain had subsided as to be almost scarcely felt. The fever progressed to recovery. I have not seen many cases of pneumonia where it was necessary to bleed, but I would have no hesitation, if all the conditions I have mentioned, of impaired respiratory and cardiac function, were present, to open a vein and proceed according to the old mode.

The following propositions may be maintained:—

1. Venesection has no direct influence over inflammation, external or internal.
2. Venesection is useless, in the case of all external inflammations.
3. Venesection is of use in these inflammations, where the cardiac and respiratory functions are interfered with.
4. Local bleeding in external inflammations is most useful, its effect is patent.
5. Local bleeding in internal inflammations, where there is a direct capillary circulation between the skin and inflamed part, is of manifest service.
6. The benefit of local bleeding, when there are not such conditions, is neither clear nor positively ascertained.

I may sum up and close my paper in the following words of Dr. Markham:—

“Is it credible that a remedy which, through evil report and through good report, has steadily held its own in the catalogue of curative agencies, from the days of Hippocrates to our own, can all at once have ceased to be of service to humanity? Must we believe that all the great minds, who, through the long ages of past medicine, have resorted to this remedy, have been using it under a delusion? Surely, the very fact of the antiquity of the remedy, its universality, and its persistence, during all times as a curative measure is strong *a priori* evidence of its possessing value and excellence as such.”

There are many questions in connection with this subject which I have omitted, and my reason for doing so is, that it would lead me into too wide a field; I may mention—bleeding in apoplexy and puerperal convulsions.

I have not done my subject the justice it merits, but I shall be sufficiently repaid if it leads to further discussion or elicits the experiences of those who are my seniors in the profession.

### ON THE ERECTION OF DWELLINGS FOR THE LABOURING CLASSES. (a)

By C. A. CAMERON, M.D.,

Superintendent Medical Officer of Health for Dublin.

ONE of the most urgently required measures for the improvement of the sanitary condition of Dublin is the erection of a large number of dwellings for the lowest classes of the industrial population.

The buildings, which have been erected by the Dublin Artisan's Dwellings Company, and the Industrial Tenements Company, afford excellent accommodation for a large number of persons. The former have now 270 tenements, containing 1,243 inhabitants. Their large two-storied cottages, containing four rooms, let at 7s. 6d. per week. Smaller sizes are rented at from 3s. 6d. to 6s.

(a) Read before the Society of Metropolitan Medical Officers of Health.

weekly. The accommodation given for 3s. 6d. is two rooms, a settle bed, yard, water supply, scullery, and water-closet. The lowest rent 2s. is given for two rooms in a large house, but even for this low rent, a separate water supply and water-closet are given.

This Company are erecting upon the Coombe area, which the Corporation has recently cleared, 220 separate cottages, and at Manor Street, 54 cottages will soon be built. The dwellings, which we owe to the zealous and truly philanthropic exertions of the Company, are hardly available for labourers. Very few of the tenements are let at so low a rent as 2s. per week. It seems, therefore, desirable that the good work done for artisans, clerks, and other persons earning a pound or more weekly, should be supplemented by the erection of dwellings for still more humble classes of the community.

There are, probably, at least 10,000 married men,—labourers, porters, and messengers, whose weekly earnings do not exceed fourteen shillings. There are some thousands of poor widows, with or without families, old worn-out men and single women, earning a precarious living, and residing in wretched dwellings. To all these classes of persons the tenements of the Artisans' Dwellings Company are as inaccessible as are the houses in Fitzwilliam Square to ordinary mechanics. It is more especially the dwellings of these classes that urgently require amelioration. No doubt the homes of artisans are, for the most part, defective enough, but still their condition is much better than that of the homes of the very poor. The weekly rents paid by several thousands of the poorest classes, vary from eightpence to two shillings. A very large number of families occupy each a single room, for which a rent of from one shilling to eighteenpence weekly is paid. In some cases the sum of two shillings is charged for one apartment.

In the houses where the rooms are let at a shilling each per week, a filthy state of things is the rule. From four to eight families often occupy such houses, and they seldom adopt any systematic arrangements for the cleansing of the common hall and stairs, or for keeping the sanitary accommodation in a proper state of cleanliness. In some instances the landlord appoints a person to keep the house and out-offices clean, but the person so appointed is generally an old woman, whose remuneration for her labour is a free room. Those house-owners, or renters, who possess a large number of the lowest classes of tenemental dwellings, employ men to clean the yards. They make incessant complaints of the filthy and destructive habits of the occupants, and protest against erecting water-closets for their use on the ground that the fittings would soon be destroyed. The dwellers in the lowest class of tenemental houses have been so long familiarised with their filthy surroundings that time is necessary to educate them into the proper use of water-closets, and other improvements, which are being steadily introduced into even the humblest class of dwellings.

In the tenements which I have just described, circulates no inconsiderable proportion of the poisons of the zymotic diseases, and more especially those of small-pox (when epidemic), and typhus fever. These, and other contagious diseases, are nursed, so to speak, in the lowest classes of dwellings, and continually spread therefrom, through many direct and indirect channels, into the abodes of all classes of the community. What a substantial gain to public health would it not be, if the, say five thousand families who now occupy the worst houses in this city, were provided with healthful dwellings!

It seems to me that the time has arrived for effecting some substantial amelioration in the condition of the lowest class of dwellings. This amelioration is not likely to be effected by any kind of building societies. It must be done either by benevolent associations, with no stinted means, or by the municipality. It is within the power of the Corporation, acting with the consent of the ratepayers, to erect, not only dwellings for the labouring classes, but also furnished lodging-houses for their use.

There are three Acts relative to the erection of dwellings for the labouring classes, namely:—

The Labouring Classes, Lodging Houses, and Dwellings Act (Ireland) 1866 (29 & 30 Vic., cap. 44).

The Artisans and Labourers' Dwellings Act, 1868 (31 & 32 Vic., cap. 130).

The Labouring Classes Dwelling Houses Act, 1867 (30 Vic., cap. 28).

Under the first-named of these Acts, the corporation (and other municipal governing bodies) are empowered to purchase, or rent land, for the purpose of erecting upon it dwellings for the labouring classes. They can also provide lodging-houses, and supply them with furniture, gas, water, and other necessaries.

When a corporation, or other municipal governing body, proposes to consider the advisability of adopting this Act, notice to that effect must be published not later than 28 days, or not earlier than 42 days, before the day upon which the question is to be discussed. If, upon that occasion, a memorial from ratepayers, representing one-tenth of the rateable value of the property liable to assessment for the purposes of the Act, be presented, requesting the consideration of the question to be postponed for a year, the prayer must be granted.

After the expiration of one year, the municipal authority may again consider the advisability of putting the Act into force, and may do so provided that a majority of the members present agree to the proposal.

The expense of executing the Act may be defrayed out of the funds available for paving, lighting, cleansing, or otherwise improving the borough, and if the funds be insufficient for the purpose, they may be increased by means of a special rate, but only with the approval of the Local Government Board, loans of money may also be raised for the purposes of the Act.

The closing of tenements unfit for habitation, is now a daily occurrence, and the evicted persons are complaining, and with justice that they cannot find proper habitations, unless at much higher rents than they can afford to pay.

The provisions of the Artisans' and Labourers' Dwellings Act, July, 1868, relate chiefly to the improvement of tenement and lodging-houses. If they are not in a fit condition for human habitation, their owners are liable to be compelled to improve or rebuild them; and if they refuse to do so, the municipal authorities are empowered to do the work. Of course, in all cases under the provisions of the Act, the owners of premises, which the local authorities desire to have improved or rebuilt, can appeal to the courts of law.

At the present time there are houses situated in a great many parts of the city, which have been closed by magistrates orders on the certificates of the medical officers setting forth their unfitness for human habitation. I have no doubt that such of these houses, as require rebuilding, could be taken down by the sanitary authority, should the owner refuse to do so. Many of these houses have been closed for periods of one or more years, and not a few are little better than ruins. They are not only an eye-sore, but they are liable to be the receptacles of filth. If the owners of these houses fail to rebuild them within a reasonable time, they should be compelled to do so, or to allow the local authority to take, and, if considered desirable, rebuild them. This matter is now occupying my attention, and I intend, very soon, issuing certificates that certain houses now closed up are, under any circumstances, short of being rebuilt, unfit for habitation, and recommending their total demolition.

The erection of dwellings for the poorest sections of the working people is a sanitary measure, which, in my opinion, is urgently required, and which should at once be set about. It is proposed to erect dwellings for artisans upon the property at the north-western end of the city, which will soon come into the possession of the corporation.

It is most desirable that the homes of the labourers should be as near as possible to the places where they work. Men employed at the North Wall, or at Sir John

Rogerson's quay, would not care to take lodgings at Barrack Street, if they could get any kind of a dwelling nearer to the seat of their employment. There should be, say ten or twelve district sites selected upon which to erect labourers' dwellings. The following places would be very suitable for the purpose on the north side of the city:—

No. 1. The corporation property at Oxmantown.

No. 2. Bull Lane and Fisher's Lane.

No. 3. White's Lane and Eccles Lane.

No. 4. North Circular Road, near Sherrard Street.

No. 5. East Road.

South side—

No. 1. Cow Parlour.

No. 2. Bow Lane.

No. 3. St. Michael's Hill to Cook Street.

No. 4. Wood Street, Oliver's Alley, and Arthur's Lane.

No. 5. Gloucester Street, South.

No. 6. Boyne Street.

With respect to each of these proposed sites, a few observations is necessary.

*Southern Sites.*—No. 1. As the corporation will soon be the possessor of a large district in the north-west portion of the city, a large number of dwellings for labourers might be advantageously erected in that locality.

No. 2. Several of the old houses, which comprise Bull Lane and Fisher's Lane, have been closed on account of their unfitness for human habitation; several of the remaining houses have either fallen down, or have been taken down. These two lanes comprise some of the worst tenemental dwellings in this city. They run parallel to each other from Pill Lane (in older times, a street in which dwelt many practitioners of the healing art) to Mary's Lane. The removal of the houses which remain in these lanes would leave a good open space, upon which about fifty houses for labourers could be built without encroaching unduly upon the air space. The clearance of the wretched houses in Bull and Fisher's Lane; houses, too, which are only a few paces distant from our handsome courts of law, would be a great sanitary improvement.

No. 3. White's Lane and Eccles Lane lie between Eccles Street and Blessington. These houses consist of very small cottages, and some dwellings, which were originally coach-houses and stables, attached to the houses in Eccles and Blessington Streets. The demolition of these houses would make room for about fifty dwellings for artisans, due provision being made for air space, and for a small playground for children. Most of the houses are worth very little, and some of them are in ruins.

No. 4. On or near to the South Circular Road, between Summer Hill and Upper Dorset Street, there are several pieces of land at present unoccupied. Upon one or more of these, or upon unoccupied plots of ground nearer to the canal, there is ample room for building a large number of houses.

No. 5. There are several unoccupied sites on the Wharf Road, East Road, and other places in the eastern part of the city lying to seawards of the canal, available for the purposes of the Labouring Classes Dwellings Act.

*South Side.*—No. 1. At or near Cow Parlour, in the south-western extremity of the city, there are waste spaces upon which houses could be built without any clearance of existing dwellings being necessary.

No. 2. Bow Lane and Bow Bridge. Many of the houses in these places have recently been closed up. It would be desirable to make a clearance of them, and of some others, and to erect, in their place, forty or fifty new dwellings. There are alternative sites not far off; for example, at the rear of Upper James Street, Mount Brown, &c.

No. 3. St. Michael's Hill and Cook Street. A large block of buildings at St. Michael's Hill, extending to Winetavern Street. It has been closed for about a year past. I had certified that it was unfit for human habitation. Some houses in Cook Street, close by, have been pulled down, and close to Schoolhouse Lane there is an open space. It would be most desirable to build a sub-

stantial number of labourer's dwellings on a space provided by a clearance from Winetavern Street, to about midway up Cook Street. This site would be a convenient one for the working classes, as it is situated in the most densely inhabited part of the city.

No. 4. Wood Street, and Arthur's Lane. The greater number of the houses in Wood Street have been tenanted and closed up by magistrates' orders, at the suit of the sanitary authorities. The street has long been an unhealthy one, and it would be desirable to clear away all its houses—they are very old—and make an open space, extending to Golden Lane, or, at least, to the rear of Golden Lane. Wood Street has decayed to such an extent that this year reference to it is omitted from Thom's Street Directory.

No. 5. Gloucester Street, South. This is a very poor street, and there are places near to it equally decayed. A site might be got cheaply in this locality. It would be convenient to the coal porters, many of whom reside in the district.

No. 6. Boyne Street. Many of the houses in Boyne Street, and in the courts and lanes near to it, are in a bad state, and it would be desirable to raze them. Boyne Street, or some place close to it, would be a good situation for the residence of labourers employed in the south-eastern parts of the city. There is a large open space in Boyne Street, upon which a large number of houses might be built. This, and the other sites mentioned, might be procured at no great cost, simply because they are of very little value, and also owing to there being alternative sites procurable, their owners would not ask much more than their actual value.

I do not suggest that labourers' dwellings should be erected on that quarter of the city lying south of Upper Mount Street, and east of Stephen Green and Harcourt Street, as the sites there would be expensive. Nor is it desirable that the most fashionable quarter of a city should be selected for the erection therein of dwellings of the humblest kind.

I shall now enter into a brief description of the kind of dwellings which, in my opinion, should be erected.

Each should consist of a two-storied house, containing four rooms. The dimensions of two of these should be 12 feet in length, 12 feet in breadth, and 12 feet in height, a capacity of 1,728 cubic feet, and 2 rooms 10 feet  $\times$  10 feet  $\times$  12 feet = 1,200 cubic feet. The house need only be of the plainest kind, but the stairs, doors, and window frames should be heavy and strong, so as to withstand rough usage. Water and water-closets should be provided. The cost of such a house would not be more than £120 or £125, and of the site, say £25. If each house cost £150, then 666 could be erected for the sum of £100,000. The average number of individuals per family is about 4.5; therefore, the 666 tenements would provide for (at the rate of two families per house) 6,000 persons.

For each tenement of two rooms, the rent should be 2s. per week. This is somewhat more than many labourers pay; but I am sure there would be no difficulty in getting tenants for two good rooms at such a low rent. The existence of such 1,332 tenements would stimulate the owners or renters of the ordinary low class tenemental dwellings to a healthy competition, which would be the means of causing a general improvement in the condition of the homes of the people.

It is a serious question for the ratepayers, would the erection of 666 tenement houses, such as I have described, entail a permanent burthen upon the city? I do not think it would. Let at £10 8s. per annum per house, the revenue would be £6,926. £4,500 a year interest, which would gradually extinguish the debt on the loan required to build the houses would be paid out of the rent, supposing that even a considerable number of tenants were defaulters. £1,000 per annum would be more than sufficient to keep the houses in repair.

## ANIMAL VACCINE, HOW IT IS PROPAGATED.

We are indebted to Dr. F. W. Campbell, editor of the *Canada Medical Record*, for the following account of animal vaccination as practised in Montreal, which will be read with especial interest in this country, now that the subject of small-pox is attracting universal attention.

Small-pox may be said to scarcely exist in Montreal at the present time, and the closing of the small-pox hospital is seriously contemplated. There can be no doubt that this very satisfactory state of things is largely due to the supply of pure lymph which has been at the disposal of our public vaccinators for the past three years.

Through the courtesy of Dr. Bessey our reporter visited his vaccination stables, and was shown the vaccine disease in a well-developed stage on a handsome young heifer. None but the best animals are fit for the purpose. This animal, which had been vaccinated seven days previous on the inside of the buttocks, previously cleanly shaven for the purpose, was literally covered over the vaccinated region with well-defined genuine cow-pox pustules, singly and in groups of six to ten.

Fig. 1 gives the appearance presented on this heifer.

FIG. 1.

Another choice heifer stood in a stall awaiting vaccination from this animal, one being vaccinated from the other consecutively. This has been kept up in uninterrupted succession from the original cases of spontaneous cow-pox found upon the Leney Farm, Longue Pointe, in November, 1877, of which Fig. 2 is a representation.

FIG. 2.

There has already been furnished from this source

lymph for the vaccination of over 50,000 persons, with uniformly mild and gratifying results. It is now used by the profession from Halifax to Winnipeg in Canada, and by a goodly number of the profession in the border States. Lymph has been sent to members of the profession in England interested in vaccination, and to Dr. Buchanan, of the National Vaccine Establishment, Whitehall.

During last winter vaccine was furnished from this stable for the vaccination of the viceregal household of the Princess Louise at Ottawa, and used by Dr. Grant, physician to H.R.H. At that time a variolous epidemic prevailed in many parts of Canada, and to meet the increased demand several heifers were vaccinated at one time, but the number is diminished to one every eight days in ordinary times, which is absolutely necessary to keep up the succession and prevent delays. The city is furnished once a month at present with a fresh stock direct from the animal, and most of the city physicians obtain their supplies here, so that the absolute purity and the protective power against small-pox of true Jennerian vaccination is guaranteed. Dr. Bessey is full of hope that one day the Government may be able to spare sufficient money from their railway and other enterprises to establish a National Vaccine Institute where this mode of supply would be perpetuated to future generations.

#### HOW IT IS DONE.

Two appliances for managing the animal stood in the stable—one, a strong wooden frame held together with iron bolts, supported a suspended sheet of canvas over two rollers. This is used for large animals, which are driven in and the head securely fastened, after which the sheet of canvas is adjusted under the belly, and by a turn or two of the rollers the animal is suspended a few inches from the ground, the feet being fastened to prevent kicking, while the shaving and vaccinating goes on. The other is a strong wooden frame supporting a tumbling table. This being upright the animal is brought alongside and securely strapped thereto, as shown in Fig. 1. It is then upturned, and the animal finds itself on its side and perfectly helpless, unable to make the slightest resistance to the operator, who proceeds either to vaccinate or collect the lymph as the case may be.

Fig. 3 illustrates the plan of construction of this table, which is modelled on the plan of those in use by Prof. Depaul, France, and Dr. Martin, Boston, U.S., no originality being claimed for it.

FIG. 3.

The animal being thus perfectly secured, the vessels are pinched up and ruptured, when a clear watery-looking lymph exudes. This is collected upon ivory points (specially made for the purpose) and spread out on a shelf to dry. A number of the vesicles are usually left untouched to dry up and form scabs which are still preferred to points by many senior practitioners. The points are then carefully wrapped up in cotton wool, to prevent the absorption of moisture from the atmosphere, and

next in blue paper to prevent the action of the sunlight, which rapidly destroys any virus exposed to it. They are then wrapped in tin-foil to preserve an equal temperature, and finally enveloped in rubber tissue, hermetically sealed, to preserve them air-tight when transmitted to a distance. With each package sent out, bearing date and registration, is a printed sheet of directions and observations on the use and preservation of vaccine. Any package proving inert is also replaced with fresh active virus. By this means the public sentiment among the masses of the City of Montreal has been entirely changed in favour of vaccination. Small-pox is so far extinguished that the Board of Health have decided to abolish the Small-pox Hospital, and we hear no more of ulcerated arms from vitiated virus, or small-pox following vaccination with degenerated lymph.

In a fortnight all traces of the disease disappear from the animal, which is then disposed of, and fresh animals are provided to take their place, these not being again susceptible to the infection.

The history of the Longue Pointe stock of vaccine may be given briefly as follows:—On November 6, 1877, Dr. Bessey visited the farm of Mr. John Leney (since deceased), at Longue Pointe, opposite the Provincial Lunatic Asylum, and found there six animals affected with cow-pox in various stages of development. From these cows sufficient lymph was taken to make a beginning, and on November 7th the first child in Montreal (one Michael O'Mara) was vaccinated successfully with this stock of lymph. Animals at Logan's farm were also inoculated with it, and thus, from animal to animal, and child to child, the stock has been kept up ever since. Whenever it has been used, the results have been mild and satisfactory.

#### ADDRESS

ON THE

OCCASION OF CONFERRING THE LICENSE  
OF THE R.C.S.I., THE 5TH DAY OF MAY, 1861.

By A. H. McCLINTOCK, M.D., LL.D., &c.,  
President of the College.

GENTLEMEN,—I gladly avail myself of the privilege accorded to the President on occasions like this, to address you with a few words of counsel and advice. But first let me offer you hearty congratulations on passing through the ordeal of your final examination, and thus being qualified to attend here to-day and to inscribe your names on the long roll of licentiates in surgery of this College. I hope that none of you feel surprised at this result of the examination, as though it were a matter of chance, but that you are rather disposed to regard it as the expected, legitimate consequence of honest exertion, diligent study, and careful preparation. Where these are used, any man of moderate abilities may reckon with confidence on passing the examinational tests required by this College, and may do this by his own honest exertions, without any adventitious aid whatever. Let me earnestly impress on you, gentlemen, that the same diligence and application which have triumphantly carried you through the portal of surgery, and made you legalised practitioners, will need to be continued, though under different circumstances, if you are actuated with an honourable ambition, to be conscientious successful practitioners, and to

“Snatch the meed of envious fame.”

Do not imagine because you are possessed of the much coveted Letters Testimonial, that your studies are over and your period of probation at an end. If you entertain any such delusive idea the sooner it is dispelled the better, for no notion more fatal to your advancement, more obstructive to your prosperity, could enter your heads.

Up to this epoch in your career the tribunal of a court of examiners formed the boundary and ultimatum of your hopes and fears, but failure in this ordeal could be repaired by a few months of diligent application. Henceforward, however, you

stand before quite a different, and a more important tribunal; one from whose decision there is no appeal, namely, the bar of public opinion. This tribunal, let me tell you, is slow in forming and slow in pronouncing its dictum; but though it has leaden wings, it has iron claws. It notes your moral and professional conduct, it measures your skill and your abilities, it makes itself acquainted with your habits at home and abroad; it will scan your motives, and seldom fail to find out whether the mere acquisition of lucre, or the faithful discharge of your noble calling, is the end and aim of your studies and exertions; and woe to him on whom it pronounces its sentence of condemnation! How necessary, therefore, is it that you should be duly furnished and prepared before you submit yourselves to so searching a scrutiny!

How is this to be done? you'll ask. Well, I need hardly answer this question; your own sense must tell you it can only be done by steady application and unremitting self-culture. Keep pace with the improvements in your profession, and above all things lose no opportunity of studying disease at the bedside, and thereby strengthening your powers of observation and your skill in diagnosis. Without this constant perusal of the book of Nature, all your reading will avail but little towards making you sound practitioners.

Gentlemen, I have said that ours is a noble calling. In dignity, in importance, in its capacity for good or evil, there is only one profession its superior—the clerical profession—whose members occupy themselves with the interests of our immortal souls; whilst our vocation is to preserve the tenement which the soul inhabits during its sojourn in this world. Of all the material works of the Divine Artificer, the human body is at once the most perfect and the most complex; truly, in the words of the Psalmist, we are *fearfully and wonderfully made*. To correct its aberrations, rectify its faults, preserve the due balance and harmony between its several parts, to counteract the progress of decay and resist the disturbing influence of disease, to repair the manifold injuries and accidents to which it is exposed—all these, and much more, is the business of the physician and surgeon.

Thus, you see, gentlemen, what a high trust and great privilege are committed to us medical men; but proportionately great are our responsibilities for the faithful and diligent discharge of this trust. If in disregard of its sacredness we negligently or wantonly trifle with it, we must expect not only disappointment and failure in this world, but the censure of the Supreme Judge, when called to account for the use we have made of the precious talent entrusted to our care.

Did time permit, I would like to make some remarks bearing on the *ethics* of our profession, in its relations to the public, to our patients, and to our medical brethren. A great deal has been said and written on this subject, but the sum and substance of it all is comprehended in one sentence; and if in all cases and under all circumstances you act up to the letter and spirit of the golden rule—"To do as you would be done by,"—and you let it be seen that such is the rule and main-spring of your conduct, depend upon it you will seldom get into trouble. And if, unfortunately, you do, you will stand acquitted in the judgment of every right-minded man who knows your true motive and your *bond-fides*.

Gentlemen, I need hardly tell you that, as Licentiates of this College, its charters confer upon you the privilege "to exercise and enjoy all rights of practice in the art or science of surgery." You have "free access to the library and museum of the College," and "are eligible or admissible to the rank of Fellowship of the said College." But they do not invest you with any corporate privilege. You have, therefore, no direct influence in the management or administration of the affairs of the College, having no voice in the election of the Council, which is the governing body of the College, "exercising the powers and privileges, and performing the duties and functions of the said body, politic and corporate, as the Governing or Executive Council of the said College as lawfully representing the same." In order to participate in these privileges, and to possess a real substantive interest in the College, as well as to gain for yourselves a higher and more respectable status in your profession and before the public, I would urge each and all of you to obtain the honourable distinction of Fellowship as soon as you possibly can.

Of the interests of its Licentiates, as well as of its Fellows, the College is ever mindful. On this you may

fully depend, so long as you keep inviolate the declaration you have just now solemnly taken, and prove obedient to the statutes, bye-laws, and ordinances of the College, always endeavouring "to the utmost of your power to promote the reputation, honour, and dignity of the said College."

Now this declaration does not impose any hard obligation upon you. Far from it. Be assured that in carrying out the latter part of it, you will also be doing what is most calculated to serve your own welfare, and promote your own individual advancement. For, by a coincidence not often met with in the affairs of life, the duty you owe to your College will in truth coincide and run parallel with your own self interest; and the higher you stand for professional skill, the more you elevate your own position in the social scale, and the greater the estimation in which your moral character is held for integrity and principle, by so much will you add to the reputation, honour, and dignity of the College whose diploma you now hold:

## Clinical Records.

### MEATH HOSPITAL AND CO. DUBLIN INFIRMARY.

#### BRIEF NOTES OF OPERATIONS.

Under the care of LAMBERT H. ORMSBY, F.R.C.S.,  
Lecturer on Clinical and Operative Surgery.

Reported by Mr. PERCY NEWELL.

#### OPERATION I.—*Removal of Large Tumour in close proximity to the Right Parotid Gland.*

John H., admitted to Meath Hospital April 16, 1881, suffering from an encysted tumour, growing apparently from the anterior surface of the right parotid gland. Its growth had been very slow, and it was freely moveable. Operation performed on Wednesday, April 20, 1881, the patient being fully etherised. The skin over the tumour was pinched up, and transfixed with a sharp bistoury, the anterior portion of the growth was then laid bare, but it was found to have some very deep attachments, and it was no easy matter to detach its posterior connections, with the aid of the finger nail of the operator and the handle of the scalpel—and at the same time seizing the tumour with a vulsellum forceps, the growth was thus removed. Smart hæmorrhage followed from three vessels which were commanded, and the edges of the wound were then brought together by silkworm gut sutures, and direct union took place. In a fortnight the patient left the hospital with no bad symptoms or deformity of facial muscles.

#### OPERATION II.—*For Bent Knee from Contraction of Hamstring Tendons.*

George W., æt. 11, admitted to Meath Hospital with contraction of right knee-joint—the result of a fall received some months since.

Operation performed on Wednesday, April 20, 1881. The patient being placed under the influence of ether, the tendons of the semi-tendinosus and semi-membranosus were divided subcutaneously with a sharp tenotome, a straight splint was then applied, and the malposition of his limb rectified.

#### OPERATION III.—*Excision of Right Breast.*

Mary K., æt. 60, admitted into Meath Hospital on March 28, 1881, suffering from a tumour of right breast, which on examination, after the operation, proved to be scirrhus. History states that she was the mother of a number of children; always enjoyed good health till about twelve months ago, when she noticed a kernel in her breast, which gradually got larger and she experienced severe darts of pain from time to time through the affected part.

Operation performed on Wednesday, April 6, 1881. The patient being placed under the influence of ether,

two semi-elliptical incisions were made parallel to the great pectoral muscle, the arm at the same time being well abducted from the side. The tumour having been removed, two vessels were tied, and the wound well syringed out with cold water so as to remove all blood clots, and having been swabbed out with a 40-grain solution of chloride of zinc, the edges of incision were evenly brought together without any unnecessary tension with silkworm gut sutures, a large pad of lint was placed over all, the arm was bandaged to the side, and the operation thus completed. Nearly the whole of the wound healed by the first intention.

#### OPERATION IV.—*Epithelioma of Lower Lip—Removal.*

Daniel S., a countryman from co. Meath, æt. 65, was admitted into the Meath Hospital on March 23, 1881, suffering from epithelioma of the lower lip.

*History.*—Patient states he first took notice of the disease as a small scab or sourf about 8 months ago, and can assign no cause whatever for the condition of his lip, as he is not much of a smoker, and when he does smoke he always uses a pipe with a long shank.

As there was no submaxillary glandular contamination and the man was in a very healthy condition, an operation for its removal was determined upon.

Operation performed on Wednesday, April 6, 1881. The lower lip at each side of the disease being compressed, a V-shaped incision was made, and the disease thus removed. Two hare-lip pins were inserted to bring the parts together, and kept in position by the figure of 8 twisted suture; the parts united by first intention; needles removed in four days, and the man left the hospital eight days after the operation, with very little appreciable deformity of mouth.

## Special.

### THE PROPOSED SYSTEM OF EDUCATION AND EXAMINATION IN IRELAND.

*Adopted by the Council of the Royal College of Surgeons in Ireland.*

THE Council has unanimously received and adopted the following Report of its Education Committee, in which is embodied the proposed Scheme of Education and Examination:—

The Committee report that they are of opinion that the following recommendations of the General Medical Council, should be enforced by it on all students commencing their studies after that date, viz:—

8. "No medical student shall be registered until he has passed a preliminary examination, as required by the General Medical Council, and has produced evidence that he has commenced medical study."

The Committee recommend that the following, or any one of them, be considered by the Council of the College as the commencement of professional education:—1. Attendance on the practice of an hospital, or other public institution recognised by the College for that purpose. 2. Instruction as the pupil of a legally qualified surgeon, holding the appointment of surgeon to a hospital, general dispensary, or union workhouse, or where such opportunities of practical instruction are afforded as shall be satisfactory to the Council. 3. Attendance on lectures on anatomy, physiology, or chemistry, by lecturers recognised by this College.

9. "The commencement of the course of professional study recognised by any of the qualifying bodies shall not be reckoned as dating earlier than fifteen days before the date of registration."

15. "The several branch councils shall have power to admit special exceptions to the foregoing regulations as to registration for reasons which shall appear to them satisfactory."

17. "The several qualifying bodies are recommended not to admit to the final examination for a qualification under the Medical Acts, any candidates (not exempted from registra-

tion) whose name has not been entered in the medical students' register at least forty-five months previously. In the case of candidates from other than schools of the United Kingdom, the branch councils shall have power to admit exceptions to this recommendation."

19. "That the age of twenty-one be the earliest age at which a candidate shall obtain a licence to practice, and that the age shall, in all instances, be duly certified."

20. "That no licence be obtained at an earlier period than after the expiration of forty-five months subsequent to the registration of the candidate as a medical student."

#### SCHEME OF EDUCATION AND EXAMINATION.

The Committee recommend the adoption of the following regulations:—Each student should be required to pass a preliminary examination and four professional examinations as follows:—

##### *Preliminary Examination.*

The preliminary examination shall be in the following subjects, with the permission to the student to substitute French or German for Greek.—1. The English language, including grammar and composition. 2. Arithmetic, including vulgar and decimal fractions. 3. Algebra, including simple equations. 4. Geometry, first two books of Euclid. 5. In Latin, the first and second books of the *Æneid* of Virgil, or of Jugurthine war of Sallust, or the third book of Livy. Alternative subjects.—One to be selected by the student: 1. Greek, the gospel of St. John, or the first book of Xenophon's *Anabasis*, or the dialogue of Lucian, entitled "Menippus or the Necromancy." 2. French, and 3. German, subjects to be fixed hereafter.

##### PROFESSIONAL EXAMINATIONS.

The First, Second, and Third Professional Examinations shall be held in the July and October of each year, at either or both of which the student may present himself.

That, in special cases, it shall be possible for the Council to exercise a discretion and permit students for what appears sufficient cause to pass an examination after the succeeding year has been entered.

##### *First Professional Examination.*

Candidates are recommended to attend a course of lectures on Practical Anatomy, and one on Chemistry, before the First Professional Examination. The Examination shall include the following subjects:—\* (a) *Physics*—The elements of mechanics, hydrostatics, pneumatics, and hydraulics; heat, light, and electricity. (b) The elements of chemistry. (c) Botany; physiological, structural, and descriptive. The subjects to be fixed hereafter, following as closely as may be judged right the programme of examinations of the intermediate Education Board for Ireland. (d) *Anatomy*—Human osteology. (e) *Practical pharmacy*—Elementary.

##### *Second Professional Examination.*

Candidates are required, before admission to the Second Professional Examination, to produce evidence of having passed the First Professional Examination, also certificates of having subsequently attended—Medico-chirurgical hospital, nine months. Winter courses: Practical anatomy, demonstrations and dissections, physiology, surgery, chemistry (unless attended in first year). Summer courses, three months: Practical chemistry, practical physiology, materia medica.

Candidates should be examined in—*a. Anatomy*: bones, joints, muscles, and topographical anatomy of the viscera of the chest, abdomen, and pelvis; *b. Histology*, and the physiology of the circulatory, respiratory, and digestive systems; *c. Surgery*: The signs, terminations, and treatment of inflammation, wounds, hæmorrhage, burns and scalds, ulcers, bandaging; *d. Chemistry*; *e. Materia medica*.

##### *Third Professional Examination.*

Candidates are required, before admission to the Third Professional Examination, to produce evidence of having passed the Second Examination, also certificates of having subsequently attended—Medico-chirurgical hospital; nine months as an extra pupil; or six months as a resident pupil.

Winter courses—Practical anatomy (unless attended in the first year.) Demonstrations and dissections, surgery, and medicine.

Summer three-month course, medical jurisprudence. Candidates shall be examined in—*a. Anatomy*. *b. Physiology*. *c. Surgery*—Operative, clinical, and ophthalmic surgery being reserved for the Final Professional Examination.

*Fourth and Final Professional Examination.*

The fourth professional examination shall be held in July and October, and in the April of the following year, at any or all of which candidates may present themselves.

Candidates are required, before admission to the final examination, to produce evidence of having passed the third professional examination, also certificates of having subsequently attended—Medico-chirurgical hospital, nine months as extern pupil, or six months as resident pupil, unless a certificate as resident pupil has been offered in the third year. Midwifery hospital, or maternity six months, (may be attended in the third or fourth year.) Practical instruction in vaccination. Clinical ophthalmology, three months. (may be attended in the third or fourth year, winter or Summer.)

Winter Courses—Dissections and demonstrations. Midwifery. Operative surgery—(Between 1st of April and 1st of October, in either third or fourth year.)

To be examined in—Surgery—Clinical surgery, including ophthalmic surgery, operative surgery, with surgical anatomy. Medicine. Midwifery and diseases of women. Medical jurisprudence. Candidates who possess a Diploma or Degree recognised by this College may be exempted from the necessity for compliance with this scheme in such respects, and on such terms and regulations as the Council may deem expedient.

**Department of Lunacy.**

**THE IRREGULARITIES AT THE SCOTTISH NATIONAL INSTITUTION FOR IMBECILES.**

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In an article in your issue of May 4, the subscribers to the Scottish National Training Institution at Larbert are called upon to inquire thoroughly into the working of the Institution for the last two years, and to insist that the imbecile children should be put under the guidance of an experienced medical man. There are above one hundred and twenty imbeciles in the Institution, most of them weakly in health, and many of them afflicted with epilepsy and other nervous diseases, and it seems both a foolish and a heartless arrangement that, instead of a physician in the house, they should only have a medical officer, living about three miles off, call twice a week, at a salary of £40. This is contrary to the Lunacy Acts, which requires the visiting officer to call every day at all asylums which have above 50 patients, and requires a resident physician when there are more than 100 patients. But it is probably not known that the action of the directors in appointing a lay superintendent with no resident physician, is contrary to the printed constitution of the Scottish Institution for the Education of Imbecile Children, which is given in the third and fourth reports. In paragraph 17 it is laid down that "the Institution shall be under the management and direction of a superintendent and a resident physician, but both of which offices may be held by the same person."

The directors have no power to depart from this arrangement, for it is provided in paragraph 12 that "no alteration of the constitution shall be made except at an annual or extraordinary meeting of subscribers, and notice of any such proposed change must be given to the directors at a previous meeting, and be approved of by two consecutive meetings of contributors."

As a few of the directors have, without any proper warning to their fellows, broken through the constitution made for their own guidance, any subscriber is competent to challenge this arrangement, and demand that the directors should forthwith appoint a resident physician.

For many years the directors have been virtually self-selecting; those who retire by rotation are always re-elected. The public evidently requires to be informed that it is provided that "the appointment of the board of directors and

\* The Examination in Physics may be passed either at the Preliminary or the first Professional Examination.

+ The anatomical examination of the second and subsequent years shall include dissection by the Candidate of the parts indicated for his examination and demonstration by him of dissected parts.

their chairman, and also of the treasurer and secretary, shall rest with the annual meeting of subscribers." For many years back the subscribers have simply witnessed the election of directors carried on in their presence.

I am, sir, yours, &c.,

DAVID BRUCE.

Hospital, Physician to the Hospital for Diseases of the  
Throat, &c.

(Continued from page 339.)

*Bilin.*

THIS very strong alkaline water is situated at Teplitz (Bohemia). It contains—

	Grains.
Bicarbonate of sodium ... ..	261.14
Carbonate of calcium ... ..	27.53
Carbonate of magnesium ... ..	10.66
Bicarbonate of lithium ... ..	0.50
Carbonate of protoxide of iron ...	1.00
Sulphate of sodium ... ..	51.35
Sulphate of potassium ... ..	17.56
Chloride of sodium ... ..	26.91
Phosphate of alumina ... ..	0.31
Silica ... ..	2.40
Nitric acid trace	
Ammonia trace	
Manganese trace	
Total solids ... ..	399.30

Free carbonic acid not determined.

Dr. Hassall gives the nitrogenous matter (albumenoid ammonia?) as being .022 per 100,000 parts; we found the sample which we examined remarkably free from albumenoid ammonia, containing nothing like the amount given in his analysis. We are therefore justified in stating that the albumenoid ammonia only amounted to a minute trace.

*The skeleton analysis of this water gives in the half-pint (10 fluid ounces).*

Total Solids.	Antacids.	Purgatives.	Saline
25 grains.	19 grains.	4½ grains.	1½ grains.

The Bilin water is something like the Vichy waters. It is strong and permanently alkaline—as evidenced by its action on phenol-phtalein. The alkalinity is mainly due to the large quantity of carbonate of sodium, the amount of earthy carbonates deposited on boiling being comparatively small. Therefore, the Bilin water may be considered (excepting the Vichy) as the most alkaline or antacid water that we possess. It is slightly more aperient, owing to the sulphate of soda which

is present in somewhat considerable quantity. The chalybeate quality of the water is small, but well marked. It is said that this water is much richer in carbonic acid gas than the Vichy waters, and it is claimed as an "advantage of indisputed superiority." We can hardly see that this applies to the bottled waters, as mineral waters are not bottled under pressure, like the ordinary table, soda and seltzer waters—but its keeping tendency may possibly be improved by the super-saturation of the water at the fountain head. It contains lithium, although the presence of that metal is ignored in Dr. Hassall's analysis, published about eighteen months ago.

#### Ems.

These celebrated waters, perhaps, owe their renown very much to the situation of the springs, and the mild climate. The waters may be considered as mild alkaline waters, owing their properties chiefly to bicarbonate of sodium. Their aperient action is very slight, and is due to chloride of sodium, with small quantities of Glauber's salts. The Ems waters have been very frequently analysed, and with the usual discordant results, but as they have quite recently been re-examined with great care by Fresenius, we will content ourselves with giving his analyses of the two principal springs. We have converted his calculations, however, into the usual form of grains per gallon, to correspond with our previous analyses.

The Ems waters are rather of a complicated nature.

#### Krahnchen.

Bicarbonate of sodium ...	...	148.370
Chloride of sodium ...	...	70.840
Sulphate of sodium ...	...	1.370
Sulphate of potassium ...	...	3.280
Bicarbonate of lime ...	...	17.240
Bicarbonate of magnesium ...	...	15.050
Bicarbonate of protoxide of iron ...	...	0.160
Bicarbonate of magnesium ...	...	0.072
Bicarbonate of baryta ...	}	0.011
Bicarbonate of strontia ...		
Phosphate of alumina ...	...	0.032
Silica ...	...	3.790

#### Skeleton analysis of $\frac{1}{2}$ a pint 10 fluid ounces—

Total Solids.	Antacids.	Purgatives.	Salines.
16 $\frac{1}{2}$ grains.	10 $\frac{1}{2}$ grains.	$\frac{1}{2}$ grain.	4 $\frac{1}{2}$ grains.

Of the deaths last week in the large towns from diseases of the zymotic class measles showed the largest proportional fatality in Sheffield, Bristol, and London; scarlet fever in Wolverhampton and Hull; and whooping-cough in Sheffield and Salford. The 30 deaths from diphtheria included 12 in London, 7 in Glasgow, and 4 in Portsmouth. The deaths referred to fever (principally enteric) were exceptionally few; the death rate from this cause was highest in Liverpool and Glasgow. Small-pox caused 94 more deaths in London and its outer ring of suburban districts, one in Dublin, one in Oldham, and not one in any of the other large towns,

## Transactions of Societies.

### CLINICAL SOCIETY OF LONDON. FRIDAY, MAY 13.

JOSEPH LISTER, F.R.S., President, in the chair.

THE report of the Committee appointed to consider the question of hip-joint disease and operation for it, was read by Mr. Howard Marsh, and will be printed in the "Transactions" of the Society.

Dr. THOS. WHIPHAM on

A CASE OF AORTIC ANEURISM ENROACHING ON THE TRACHEA AT ITS BIFURCATION DEMONSTRATED DURING LIFE BY THE LARYNGOSCOPE.

A carpet cutter, æt. 49, was admitted into St. George's Hospital, under Dr. Wadham, on March 7th, 1881, almost speechless, and suffering severely from dyspnoea. The man had had no serious illness in his life and had not suffered from syphilis. There was no history of asthma, and his occupation did not involve any severe strain. He had never before experienced an attack like the one for which he was admitted. He had for some weeks suffered considerable pain under the right scapula, and he had been treated for dyspepsia. On the morning of March 7th, when he was going to his work he was suddenly seized with a most severe attack of dyspnoea, which rendered him speechless and almost unconscious. He was brought at once to the hospital, and on his admission at 8 a.m., was in a state of extreme dyspnoea, ashy pale, unable to speak, and heedless of anything said or done. His hands were cold, and his breathing stridulous. Leeches were applied to the throat, and he was ordered a mixture of ether and chloroform. By 10.30 a.m. his respiration had become perfectly natural, and his voice, though weak, was natural in tone. The heart was not obviously out of position; a systolic bruit was heard over the base, and to the right of the sternum. No abnormal pulsation or thrill was detected. The pulses in the radial arteries were equal and rather hard—126. Wheezing and stridulous sounds were audible throughout the chest. At 2 p.m., at Dr. Wadham's request, Dr. Whipham made a laryngoscopic examination. The vocal cords were faintly pink, but there was no swelling of the larynx, and all movements of the cords were perfect. The first two or three rings of the trachea were visible and normal in appearance, but below them, about three inches below the vocal cords, the posterior wall of the trachea was bulged; the mucous membrane covering the swelling was much congested. At 4 p.m. there was a sudden recurrence of dyspnoea, and without in the slightest degree aggravating the patient's distress, a second laryngoscopic examination was made. The bulging of the trachea was visible as before, and the movements of the larynx were perfect, in fact the extent of the abduction of the cords was unusually great. The various remedial measures proved unavailing, and the patient was suffocated at 8 p.m. At the post-mortem examination an aneurism was found involving the descending portion of the aortic arch, and the commencement of the thoracic aorta, from the right of the upper part of the sac a secondary aneurism with thin soft walls arose, and this secondary aneurism had flattened and produced a certain amount of atrophy of œsophagus, and had caused the bulging seen just above the bifurcation of the trachea. The diagnosis during life was that a tumour (in all probability an aneurism was the cause of both the appearances and the symptoms) and the case was adduced as being a rare instance of actual demonstration of an aneurism pressing on the trachea at its bifurcation. The sudden access of the symptoms were possibly explained by sudden dilatation of the thin walls of the secondary aneurism.

Dr. WILLIAMS asked if there were no physical signs of aneurism observed? The tumour in the case described was so large that it should have yielded some sign of its presence. The case was evidently a rare one.

Dr. SEMON described a case which had been under his care last year, and in which, although aneurism was suspected, there was no positive symptom of it. Tracheotomy had been suggested for relief of severe attacks of dyspnoea. In such cases he urged, the chances should be fully described to the patient,

and no doubt be allowed to remain as to the perilous nature of an operation. In his own case the patient was relieved by surgical means, but died ten days afterwards from bursting of the aneurism. Dr. Semon presented a theory in explanation of the varying conditions of paralysis affecting the laryngeal muscles, according to which the recurrent laryngeal nerve is constituted of numerous distinct bundles of fibre, these being in communication with separate ganglionic centres, whence special stimuli proceed to particular groups of muscles. In agreement with this supposition arises the need for considering not alone local injuries in such cases, but that also occurring in the central organ.

Mr. GOLDING BRID detailed the case of a man under treatment in Guy's Hospital. In this patient were observed certain symptoms of a pulsatile tumour suggestive of aneurism of the arch of the aorta. There was intense pain of the right shoulder also. A few weeks ago the man had returned again to hospital, after having been some time absent. At that time the right wall of the trachea was, when he examined with the laryngoscope, plainly seen to be bulging in, breathing was stridulous, there was a pulsatile tumour in the neck, and the right pulse was smaller than the left. On coughing, the pulsation of the tumour ceased, but its size was much increased if the breath was held, slowly returning again subsequently, to its usual dimensions. There was no inconvenience produced by laryngoscopic examination. A swelling within the tube, first seen by the house surgeon, was not apparent at the earliest examination made. Operation was resorted to, the tumour being cut down upon, and its aneurismal nature demonstrated. A ligature was put round the common carotid, and improvement in the patient's condition resulted. He subsequently died, however, when the post-mortem showed a large innominate aneurism, with others in other parts of the body.

Dr. ORD had observed two instances in dead bodies in which the paralysed cords were permanently adducted, the abductors being wasted away and the recurrent laryngeal nerve much affected. The introduction of laryngoscopic examination would prevent the repetition of errors formerly committed in performing tracheotomy to relieve dyspnoea due to aortic aneurism.

Dr. LONGHURST commented on the remarkable way in which aneurism continues for years. He asked if the pupils had been examined in Dr. Whipham's case and to what precise cause death had been attributed?

Dr. WHIPHAM said no other signs of aneurism than those enumerated in the paper had been observed. Nothing more than had been done in the case was possible. The laryngoscopic examination showed tracheotomy to be impossible. The recurrent laryngeal nerve was unaffected; there was no paralysis of the cord, neither any alteration in the size of the tumour from time to time. The pupils were not examined. The patient died from suffocation.

Dr. DOWSE on

#### A CASE OF ANOREXIA NERVOSA.

A. T., *æt.* 14, was admitted into the Hospital for Epilepsy and Paralysis on July 5th, 1880, with the following history. Family history good; her parents are healthy and strong, also her brothers and sisters. She was always considered to be a delicate child, and during her infancy cod-liver oil was given to her on account of her weakness. In the early part of last summer she began notably to decline, stating that she could not swallow food, and exhibiting great obstinacy of disposition. She would cry at the slightest opposition to her wishes, and often without any apparent reason. Being a delicate child she had always been treated with more indulgence than the rest of the children, and in her sullen fits at this time she would never speak to her mother except in tones of the greatest insolence. She grew from bad to worse, and in February last year she went thirteen days without taking anything besides a little water—at least, not to anybody's knowledge. She became so weak that her parents sat up with her for nearly a week, and one night she was thought to be dying. It is supposed she had a fit on one occasion, and it was thought she was dead. She would never begin a conversation or join in one, and it would sometimes be difficult to get a reply from her even in a monosyllable. Her aversion to food of any kind was most marked. When she first came under Dr. Dowse's care she was unable to stand without assistance. The eyes were downcast, and the cheek bones were prominent, from wasting of the cheeks, and the angles of the mouth were drawn down, so that she looked the picture of misery. The

voice was scarcely audible. She was taciturn, shy, and reserved. There was a general morbid state of functional inactivity; all her movements were slow, and her mind was equally inactive. The breath was offensive, the tongue fairly clean, the bowels obstinately confined, and the evacuations were pale and clay coloured; the temperature was never over 98° Fahr., and frequently below it. The extremities were cold, and of a bluish colour. The special senses were normal; the pupils of the eyes were sluggish; pulse 120, resp. 20. There was no marked anaesthesia of the fauces; no globus, or other hysterical symptoms. Upon her admission considerable difficulty was experienced in getting her to take food, but forcible feeding was never had recourse to. She was in the hospital for two months, and her condition upon admission and departure was very striking and characteristic. She had gained considerably in weight, and instead of being taciturn and reserved, she was cheerful and agreeable to all about her, and took food without any reserve or hesitation. The cure was unquestionably brought about by the frequent administration of fluid nourishment. It was made compulsory for her to take in the course of twenty-four hours three eggs, one pint of the strongest beef-tea, three pints of milk, and three ounces of brandy. No medicine was administered, excepting half a drop of croton oil occasionally to relieve the bowels.

Dr. WILLIAMS had seen several similar cases brought to hospitals as consumptives, but he did not think their diagnosis at all difficult. They were always markedly cold, and could with difficulty be induced to take food. He had succeeded in persuading them to do so by stimulating their vanity, hinting at improved personal appearance, &c. When persuasion, however, failed, he considered force must be employed.

#### Mr. A. PEARCE GOULD on a CASE OF RAPID DEATH AFTER ANTISEPTIC OSTEOTOMY OF THE TIBIA.

J. T., *æt.* 8, a healthy country lad, was operated on for a bad rickety deformity of the left tibia. At 2 p.m., on Oct. 27th, 1880, strict antiseptic precautions were observed, the bone was divided with a chisel which, on account of the extreme hardness of the bone, had to be introduced into the wound three times. The lad slept through the night, and next morning was free from pain, and apparently well; he ate a light breakfast of bread and milk. At 11 a.m. he was sick, and vomiting and diarrhoea continued through the afternoon and evening, when collapse set in, and in spite of vigorous stimulating treatment, he died 36½ hours after the operation. When seen by Mr. Gould five hours before death, he was conscious, blanched trunk, and lower extremities warm, pupils small, pulse hardly perceptible, and very rapid, and respirations 44, but unimpeded; there had been complete suppression of urine since the early morning; the vomited matter was abundant and watery. At the autopsy the blood generally was fluid and dark, in the largest veins were partial soft clots; no staining of endocardium; no petechiæ. Spleen, liver, heart, and brain, healthy. Trachea and bronchi intensely congested with excess of mucus. The other organs were apparently healthy, but on microscopic examination of sections, prepared by Dr. Gibbes, and shown at the meeting, the minute pulmonary vessels were found to be filled with blood clot, and minute foci, of commencing inflammation, were found scattered through the parenchyma. Similar minute inflammatory foci were found in very small numbers in sections of the kidneys. Sections through the stomach showed the mucous membrane to be intensely inflamed, the glandular structure being almost entirely destroyed; the inflammatory exudation extended also into the sub-mucous tissue. The wound itself showed no unhealthy appearances; the medulla of the divided bone was not crushed, and no sign of fat embolism was anywhere apparent. Mr. Gould remarked that the clinical and pathological features of the case excluded, as the cause of death, shock, anaesthesia, the acute specific diseases, erysipelas, pyæmia, and fat embolism, but they pointed to the presence of some intense irritant in the blood. The presence of septic intoxication was negated by the absence of any sufficient source of infection, and of pyrexia, by the presence of inflammation of the stomach, kidneys and lungs, by the absence of general visceral congestion, and capillary congestion. As the ingestion of any irritant might be excluded, Mr. Gould discussed the question of the production of the fatal illness by carbolic acid. He showed that the vomiting, diarrhoea, nervous symptoms and temperature, were quite

in accord with the symptoms undoubtedly produced by carbolic acid, although suppression of urine was a new fact. As nothing was before known of the minute changes in the apparently healthy organs in carbolic intoxication, we had to rely upon the symptoms only for deciding the cause, but it was held that the pathological changes did not contra-indicate the influence of carbolic acid. The quantity of the acid absorbed was probably very small indeed, but children are more susceptible to its influences than are adults. Idiosyncrasy also plays an important part in such cases, and there is no evidence of the minimum fatal dose of the acid in man. In conclusion, Mr. Gould maintained that his case was one of carbolic intoxication, and he was led to this view from the absence of other cause of death, and of any facts to negative it, and because the symptoms and post-mortem signs, with few exceptions, were those observed in that affection.

The President agreed in the conclusion as to the cause of death, though he thought it a misfortune the urine had not been examined. The patient happened to be extremely susceptible to carbolic poisoning, like a lady he had treated in whom the application of carbolic dressing induced vomiting, which ceased on the substitution of boracic dressings, but came on again each fourth day when fresh dressings were applied under carbolic spray. Oil of eucalyptus, he had discovered, was a perfect substitute for carbolic acid, and was both non-irritating to the skin, and non-poisonous to the system. The volatile oil could be fixed by dammar-gum; and for gauze he recommended a mixture containing oil, 1 part; dammar, 3 parts; paraffin, 3 parts.

#### SOCIETY OF METROPOLITAN MEDICAL OFFICERS OF HEALTH.

THIS Society met on Wednesday, 20th April, at the Royal College of Surgeons, Dublin. The President, Dr. C. A. CAMERON, in the Chair.

It was resolved that the term metropolitan should, in future, be omitted from the designation of the Society, the membership of which would therefore be open to all the medical officers of health in Ireland. Applications for enrolment to be made to the Hon. Sec., Dr. Pollock, Royal College of Surgeons. The President read a paper on

ERECTION OF DWELLINGS FOR THE LABOURING CLASSES, which will be found on page 417.

The Right Hon., the Lord Mayor, proposed a vote of thanks to Dr. Cameron, and during his observations, strongly supported the proposition put forth in the paper, as did also Mr. Drew, R.H.A., who seconded the resolution. The Hon., the Recorder, and several members and visitors, also spoke strongly in favour of the adoption of Dr. Cameron's suggestion, and on the motion of Dr. Moore, seconded by Dr. Chapman, a resolution to the effect was adopted, and ordered to be submitted to the corporation.

A MURDEROUS attack was made on Wednesday last upon Dr. Wall, one of the physicians of the Cork workhouse, by an able-bodied inmate named Keller, who, having concealed himself in a recess, attacked the doctor as he was entering the workhouse, and delivered several blows on his head with a poker. One wound was over an inch long, but fortunately there was no fracture. Keller was arrested and placed in the bridewell.

On Wednesday last the annual dinner in aid of the funds of St. Mary's Hospital, was held at Willis's Rooms, Earl Stanhope in the chair. The munificent bequest of £25,000 by the late Mr. Stanford, for the purpose of enlarging and improving the building, was mentioned; and in reference to the maintenance of the new wing, the chairman suggested that paying wards, similar to those in use at St. Thomas's, should be established, and that the payment of a certain sum should be required of out-patients.

"SALUS POPULI SUPREMA LEX.

WEDNESDAY, MAY 18, 1881.

#### ANTISEPTIC DRESSING.

WITHIN the past few months there have been recorded, both in home and foreign papers, a very considerable number of accidents due to the toxic influences of the carbolic acid used in operating under Listerian precautions. Naturally, as more has become known concerning the facility with which some susceptible constitutions yield to these poisonous effects, increasing anxiety has arisen lest the greatest benefit of the century should be brought into disrepute by reason of the misfortune attending its employment in some cases. And that the fear has not been an idle one has been occasionally demonstrated already, the opponents of antiseptic surgery having been quick to seize on the evidence of carbolic acid poisoning as proof against the value of the system. Every case in which serious or fatal consequences have followed the application of the phenol is promptly turned to show the mischief to be anticipated from a departure along new paths; and, in the same way as anti-vaccinators are prone to lay all deaths among the vaccinated to the door of impure lymph, so, in turn, as the non-antiseptic school gathered strength in its growth, might we have had to contend against assurances that the evils of aseptic surgery were worse than those it was destined to remedy.

Not long ago an American contemporary contained the account of a case in which death ensued after hyper-distension of an abscess with carbolic solution, 1 in 40; and in this instance there were the unmistakable evidences of poisoning due to the antiseptic agent. In recent months somewhat similar cases have, from time to time been stated in the medical journals, while it is by no means unusual in ordinary hospital practice to meet with individuals who exhibit a greater or less constitutional antipathy to even the odour of carbolic acid.

On Friday evening, at the Clinical Society of London's ordinary meeting, Mr. A. P. Gould read notes of a case under his care at Westminster Hospital, in which death most unmistakably occurred as a consequence of the toxic action of the antiseptic. Patient was a boy in whom a defective limb was improved by subcutaneous osteotomy. Rigid antiseptic precautions were observed throughout the operation, and the boy died some few hours afterwards, presenting symptoms that leave little possible doubt as to the cause of the fatality. It is true, the urine was not examined, but the post-mortem examination revealed sufficient renal mischief commencing to justify the assumption that it would have confirmed the opinion formed. In a certain sense this case is likely to become historical—not so much on account of its presenting any feature of extraordinary interest, but as being that in connection with which the great apostle of antiseptic surgery announced a discovery, second only in importance to that by which he is already so well known. Commenting on the case described by Mr. Gould, Professor Lister briefly referred to the proven fact that there is a class of persons who are peculiarly susceptible to carbolic poisoning, and said that he had been for some time engaged in devising a dressing and protective which, while being perfectly innocuous, should, at the same time, be absolutely aseptic. The result of his experiments has been to demonstrate that the oil of eucalyptus possesses those advantages; but, by virtue of its extreme volatility, it presented what seemed to be a difficulty in the way of its use. After trial, however, of numerous substances, he at length obtained one possessed of the power of "fixing" the oil, this being the dammar gum employed by microscopists for the preservation of histological specimens. In proof of this statement, Mr. Lister exhibited a sheet of gauze prepared according to his method, and this was strongly odorous of eucalyptus oil. The full formula according to which the solution for coating the gauze is prepared is—

Oil of eucalyptus, 1 part;  
Paraffin, 3 parts;  
Dammar gum, 3 parts;

and the process of preparation is similar to that by which the ordinary carbolic gauze is made.

We are disposed to attribute to the announcement of this discovery an importance which, for the moment, may appear extravagant; but a little reflection will convince that it is not really so. Each year—indeed, one might say each month—the limits within which antiseptic surgery obtains grows wider and wider, and thus an ever-increasing number of people are brought under its influences. Consequently, the number of those likely to be injuriously affected by carbolic acid is always being added to, and the sphere of its mal-effectiveness enlarged.

We cannot anticipate that surgery will retrograde to the position of indifferentism regarding septic conditions; rather must we feel assured that every movement will be further towards the attainment of perfect aseptic surroundings—that is, towards more and more extended application of preserving agencies. Hence the need that these shall be at once wholly beneficial in the way of protection, and absolutely innocuous to the constitutions of those they influence; else, with the progress of antiseptic surgery, will there be need to regret a constantly-increasing mortality from the very causes to which hopeful attention had been directed in the way of ultimate safety. These misgivings have agitated the minds of most of us, as we have witnessed the triumph of antiseptic surgery, and the few accidents we had been compelled to attribute to it. It is, therefore, with relief and gladness that we hail the discovery made by Dr. Lister—a discovery of which we cannot just yet foresee the whole consequences, but one which we shall be forgiven for terming "epoch-making," in the sense that it will mark the starting-point of a new era in modern surgery. How anxiously the discovery had been awaited they know who have watched with expectant dread the case which will do well, unless—the constitution is susceptible. The abolition of this unspoken dread is another laurel in the wreath of Mr. Lister's triumphs.

#### THE HELENSBURGH ENDEMIC INFLUENZA CRAZE.

TOWARDS the end of last year a series of papers appeared in the *Glasgow Medical Journal* from the pen of Dr. Henderson of Helensburgh, describing a peculiar form of "endemic influenza" with diphtheritic symptoms, as having for some time prevailed in Helensburgh and the surrounding districts, and due, as he unhesitatingly affirmed, to the "polluted waters of the Clyde—the sewage and filth of Glasgow." In common with one or two friends, and notably with a venerable and accomplished member of the profession now laid aside from its active duties, we were at the time struck with the recklessness of the deductions contained in these papers, and the palpable insufficiency of the data on which Dr. Henderson's premises were based. While Dr. Henderson's personal respectability and honesty are above the slightest suspicion, we feel constrained to believe that like too many hobby-horsical members of the profession of medicine, indigenous to certain neighbourhoods, he hastily conceived a notion which he cherished to the extent of perverting his judgment and weakening his understanding. The scientific *furors* which begot the "Glasgow [Scientific] Dairy Company," and the sewer-gas agitation, are examples of a similar mental nightmare, whose inevitable result is to hold the profession of medicine as a science up to the ridicule of the intelligent laity, and drag the conflicting testimony of medical men into the papers for the delectation of sarcastic and irreverent outsiders. Apart from the professional aspect of the question raised by Dr. Henderson, there was another, but for which we probably should have heard nothing further of Dr. Henderson's endemic, there was the money question affecting the pockets of the good people of Helens-

burgh; and it is needless to say that neither questions of Church nor State, however much they do agitate the hyperborean mind, can touch it so acutely as the one at issue. Helensburgh is a decidedly beautiful watering-place, it is a favourite summer resort for Glasgow citizens, a large number of its permanent inhabitants derive a living from house-letting in the season, and it requires no further demonstration to satisfy any one that the publicity of Dr. Henderson's endemic, and the seriousness of its nature were not, from the popular point of view, at least, of the most reassuring description.

Recognising the gravity of the situation, the Local Authority appointed a joint committee to investigate and report on the allegations as to the foreshores of Helensburgh and the Gareloch, and the consequent validity of the scientific aspect of the case as published by Dr. Henderson. The report has been made public; it is exhaustive. Eminent chemists have been employed in the investigation, and the result must be said to be not only gratifying but creditable to the Helensburgh sanitary authorities. The salient features of the case may thus be summarised:—

The sewage from the large city of Glasgow, according to Dr. Henderson, was deposited along the Helensburgh shores and adjacent localities, and in course of decomposition evolved gases which occasioned the peculiar endemic which he "discovered." In his own words, "We do not attribute much of the contaminated condition of the air to Helensburgh sewage. The quantity is very trifling compared with what is carried to our shores. Besides, the same condition is discernible over a very wide area about Cardross and at various points of the Gareloch. At Garelochhead the state of the shore and the resulting emanations are quite out of proportion to the amount of local sewage, and must therefore be caused by organic matter conveyed to the place by currents."

It will be obvious that three positions are involved in this inquiry, and that the *onus probandi* lies with Dr. Henderson. 1st. The existence of this alleged sewage contamination. 2nd. The existence of the endemic; and 3rd. The relation of cause and effect as between the two. Now, what is the evidence thereon? The denial of the committee that the Clyde is in any reasonable sense polluted as it flows along the shores of Helensburgh and Gareloch, is supported by the testimony of Dr. Angus Smith, an authority quoted by Dr. Henderson to support an opposite conclusion. From Dr. Smith's paper, "The Mud of the Clyde," Dr. Henderson quotes in support of his theory. But Dr. Smith's paper, properly viewed, is a two-edged weapon. As the amount of sewage impurity is estimated by the quantity of oxygen required to decompose the organic matter, Dr. Smith gives the amount of oxygen required to oxidise the organic matter of given quantities of various waters. Thus, with water taken from the Clyde five and a-half miles above Glasgow, 4.55 grains of oxygen were required to oxidise 100 gallons, while with water taken from the Clyde near Dumbarton, the same amount of oxygen was required to oxidise a similar quantity of water. The water is thus as pure at Dumbarton as it is five and a-half miles above Glasgow, notwithstanding the vast amount of sewage contained in the river around Glasgow. Confirmation is thus given to a very general belief among chemists that in a very short course

the organic matter contained in sewage is precipitated in water, and thus rendered innocuous. It will be obvious, therefore, that in proportion to the distance from Glasgow, the water of the Clyde becomes purer; and hence according to the authority quoted the water off Helensburgh is as pure as the water at Lochgoilhead, Wemyss Bay, Inellan, and even in the open sea within forty-six miles from Liverpool. The purest water found by Dr. Smith was off Ailsacraig, requiring as it did .35 grains compared with the foregoing.

Not content, however, with the authority of Dr. Smith, the local authority employed other chemists, viz., Dr. Stevenson MacAdam, of Edinburgh, and Wallace, of Glasgow; and the result of their labours is entirely confirmatory of those of Dr. Smith. According to these well known authorities, and employing the usual test for organic impurity, it was found that the water taken from near the pier at Helensburgh is purer than that from Lamlash, Gourrock, Dunoon, or Garelochhead; and very much purer than that from Tighnabruich or Row, though none of them are in any sense impure. The total quantity of organic matter in any sample is exceedingly minute. At Helensburgh the amount is seven hundredths of a grain of oxygen for 70,000 grains of water; the highest being little more than 1-10th of a grain. The pure open sea water from the Isle of May requires two and a half tenths of oxygen to oxidise the organic matter in a gallon. In respect of saltness, the Helensburgh water is about three-fourths as strong as the open sea water. Tested by the amount of albumenoid ammonia found in the water, the following results are disclosed:—In the Helensburgh sample of water there is eleven-hundredths of a millionth part. A small difference exists in the different samples. Compared with the published analysis of the London water supply, the following obtains:—In West Middlesex, .10; Chelsea, .13; Southwark and Vauxhall, .18; Lambeth, .16; New River, .09; East London, .18; the Edinburgh water supply from Swanston, .10; and Loch Katrine, .08. It is thus obvious that the inhabitants of London drink water having a half more albumenoid ammonia than the sea water at Helensburgh and Garelochhead. There are few cities which can boast of a finer supply of water than Glasgow, yet its inhabitants drink water, so far as this test is concerned, almost as impure as the water of the Clyde at Helensburgh. Taking the whole ammonia of the waters the case is not much altered. Selecting as pure water that off the Isle of May, Dr. MacAdam found it to contain ten hundredths of a millionth part of total ammonia, as compared with nineteen hundredths with Helensburgh water. The normal sea water selected by Dr. Wallace contained twelve thousandths of a grain to the gallon; the Helensburgh water eleven thousandths of a grain to the gallon. Several London drinking waters yield more total ammonia than our sea water. So much for the water. As the result of the examination of mud or sand from the foreshores, Drs. MacAdam and Wallace found the material on the shore at Helensburgh and the Gareloch to be in a similar chemical condition as that on the beach at Dunoon, Gourrock, Tighnabruich, and Lamlash. Lamlash beach taken as the model contains fifteen parts of ammonia and seventeen of phosphoric

acid in 100,000. The Helensburgh samples contain certain only a-half more ammonia. Another sample from Lamlash contains nearly six times as much as the model one, and four times as much as the Helensburgh shore material. There is twice as much ammonia in the shore matter at Tighnabruich as at Helensburgh. The Dunoon specimens contain, the one nearly twice as much ammonia, and the other eight times as much as the Helensburgh sample. There Garelochhead sample is similar to the Helensburgh one, and are described by Dr. Wallace as "comparatively pure." Tried by the amount of organic matter in the samples, leaving out the purer Lamlash sample, the Helensburgh and Garelochhead samples are much the purest. There is also only a small percentage of mud to the pure sand. In one of the Helensburgh samples there is only a-half per cent more mud than in the pure Lamlash sample. Without knowing the localities from which they were taken, Dr. Stevenson MacAdam selects seven which, he says, are the most pure, and four samples from the shore at Helensburgh are of the seven so selected. Turning to the sewage of Helensburgh which, to remedy the alleged local condition, requires attention, Dr. Henderson recommends the adoption of the Aylesbury plan. The effluent current at an hour when, according to the allegation of Dr. Henderson, it may be expected to be strongest being collected by the committee. The liquid from all the pipes was mixed and samples sent for analysis along with the other samples of water. Dr. MacAdam designates it a "very mild sewage;" and remarks that as it flows from the drains at Helensburgh it is nearly as free from sewage impurity as that of Aylesbury after being chemically treated by the A B C process. Dr. Wallace gives the total amount of ammonia in the final effluent at Aylesbury at 1.302, and the effluent of Helensburgh at 1.129—considerably purer than the purified Aylesbury sewage. Surely, then, if the evidence of these distinguished experts is to be trusted, and we have no earthly reason to doubt its accuracy, the death blow is dealt to Dr. Henderson's first proposition. In painful contrast with the evidence of the chemical experts, is the evidence of the local medical men as to the existence of the alleged disease. Thus, Dr. Messer, a gentleman in good practice in Helensburgh and its neighbourhood, denies all knowledge of the disease, and does not recognise any local conditions which might occasion it. Dr. M. Cameron, who practised for about two years in Helensburgh, makes a similar statement. Of course, it may be alleged that Dr. Cameron, being an eminent Scotch obstetrician was not likely, from the nature of his specialty, to see much, if anything at all, of the "endemic." Dr. Dunbar, of Garelochhead, a man of undoubted ability, is clear in his declaration that he has seen nothing of this endemic influenza. Intelligent laymen resident in Helensburgh for periods varying from ten to seventy years, declare they know nothing of the "endemic," and never suspected its existence until the publication of Dr. Henderson's "discovery." Drs. McEwen and Findlay support Dr. Henderson's contention. Surely this is a lamentable disclosure, as affecting the statements of about half-a-dozen respectable practitioners in a fashionable watering-place. The committee may well remark that if it were possible to treat the allegation as to the existence of the disease in

like manner with its alleged cause, a similar fate would unquestionably befall it. Altogether, the local authority have signally vindicated the salubrity of Helensburgh, and have laid other towns on the Firth of Clyde under an obligation. The rapid precipitation of sewage by water has been demonstrated, and the purity of the water in the Firth of Clyde made equally manifest. At the same time, by more than implication, the profession of medicine, or that section of it represented in Helensburgh, has been placed in a position which we would rather not characterise.

We hope future good may ensue. There is no section of the profession more fussy and self-sufficient than the West of Scotland medical sanitary reformers, who, with Florence flask, glass tube, and coloured water, possess a refreshing facility of *scientific* demonstration. The reign of sanitary nebulosity was inaugurated in Glasgow under the dominion of Dr. W. T. Gairdner, and the obfuscation has been ably kept up by the inconsequential prelections of his faithful lieutenant, Dr. J. B. Russell. It is all very well to hoodwink a Glasgow bailie, but rash assumption, impertinent interference with public property and public rights, and ultimate destruction of ephemeral hobbies by ruthless scientific investigation do not redound to the credit of sanitary science. We trust the "discoverer" of a new hobby will henceforth well digest it before soliciting its public acceptance, and be warned in time by the pathetic fate of Dr. Henderson's Helensburgh "endemic influenza."

#### THE CORONERS' (IRELAND) BILL.

We reported recently the rumour that the Parliamentary Committee of the College of Physicians in Ireland had recommended for adoption by the College a suggestion that medical practitioners should be excluded from coronerships.

A contemporary informs us further upon this subject. It says that the College are about to take immediate steps to communicate with Her Majesty's Government on the subject before the measure proceeds further in Parliament. In the opinion of the College the Bill is objectionable, because it proposes to continue the most objectionable features of the existing coroners' law in Ireland. The College suggests that any measure for the reform of coroners' law, which may receive the support of Her Majesty's Government, should contain as fundamental provisions:—1. That all coroners should be appointed and paid by the Crown, as other judicial functionaries are at present. 2. That every coroner should be either a barrister or a solicitor. 3. That every coroner should have at least two deputies to take his place in case of absence or overwork, and that these deputies should be qualified in like manner as the coroner. 4. That every coroner should have a skilled medical expert attached to his court; such expert to be appointed by the Government, and to determine in all cases whether a post-mortem examination is or is not necessary, and to act as assessor to the coroner. 5. That, in all cases where a medical practitioner has been in attendance shortly before or immediately after death, he should be examined as a witness, except in cases where he is charged with

causing such death. 6. That all other matters of detail as to salary and retiring allowances of coroners, should be regulated on the usual principles followed in paying judicial officials. 7. That the medical expert should be paid partly by salary and partly by fees for each inquest. 8. That all other medical witnesses should be paid fees for attending and giving evidence, in addition to expenses incurred; and that such fees should not be less than three guineas a day. 9. That a proper place should be provided, where practicable, for the performance of post-mortem examinations in connection with coroners' inquests.

We have already protested with all emphasis against the proposal to exclude medical men from coronerships, because we consider that—if the combination of both legal and medical knowledge cannot be attained, it is better that the coroner shall be acquainted with the diseases and injuries which cause death, and be ignorant of general law, than that he should have a knowledge of the law and be ignorant of the usual causes of death. But we deny on the one hand that there is any difficulty—for the doctor—in acquiring the limited knowledge of law, which the coroner needs, while on the other, the knowledge of medical science, which is necessary to form a judgment on the cause of death, is quite impossible for a lawyer. But the chief objection we make to the "medical assessor" project is that it is impracticable. Such a functionary must devote his whole time to his duties, and must be well paid, and we ask where would such officers be found to act as a medical expert and jurist for every county in Ireland?

Another objection which we raise to the proposal is that such assessor would, in great measure, supersede the medical man who was last in attendance on the deceased, and whose evidence we consider most essential to the elucidation of the cause of death, for it does not seem likely that the public will consent to pay two medical men at every inquest—*i.e.*, the doctor who gives the evidence, and the assessor, whose duty it is to translate that evidence for the benefit of the coroner, and to put the verdict into his mouth.

Of the other suggestions of the Committee we heartily approve, and hope that they may be accepted by those in charge of the Bill.

## Notes on Current Topics.

### The Small-Pox Epidemic.

SMALL-POX is now quite epidemic in some parts of London, so is the rush for vaccination both among the upper and lower classes. Each week the difficulties of the Metropolitan Asylums Board increase, for no sooner do they decide upon the erection of some temporary building to meet exigencies, than their action is met by one at law to restrain them. At the fortnightly meeting of the Board on Saturday last, an alarming increase of the disease was reported from the various fever hospitals. At Homerton 48 fresh cases had been admitted during the fortnight, 7 had died, and 42 had been discharged, leaving 141 under treatment, and no beds available; at

Stockwell 61 had been admitted, 6 had died, and 56 had been discharged, leaving 119 under treatment, and no beds available. At the Homerton Fever Hospital, which had been utilised for the reception of small-pox patients, 230 had been admitted, 20 had died, and 24 had been discharged, leaving 186 under treatment and no beds available. At Fulham 112 had been admitted, 14 had died, and 108 had been discharged, leaving 289 remaining under treatment, and 11 beds available. At Deptford 179 had been admitted, 28 had died, and 196 had been discharged, leaving 357 under treatment and 43 beds available. The total showed that 630 had been admitted, 75 had died, and 426 had been discharged, leaving 1,092 under treatment, and 54 beds available. These figures show an increase as compared with those of the previous fortnight of 300. In the city proper the authorities, with their known promptitude, have found a way out of the great difficulty of removing from their midst small-pox cases—a difficulty which up to the present has been one too much for the other sanitary authorities of London. The Port Sanitary Committee have made arrangements with the Commissioners of Sewers to receive cases on board their hospital ship *Rhin*. By this plan patients are at once isolated and at the same time removed to a healthy part of the river, and placed under circumstances favourable to convalescence.

### Medical Heroism at Maiwand.

THE *Pioneer* of India has the following account of an act of great bravery on the part of an army surgeon at the battle of Maiwand.

The Afghan guns were allowed to approach so near to the British line of defence, that shot and shell fell even into the Field Hospital tents, where the surgeons were busy at work dressing the wounded men. In one of these tents Surg. E. A. H. Roe, Army Medical Department, was attending to a British soldier whose leg had been shattered by a shell. It was just at this time that the troops broke and the retreat began; and Dr. Roe, looking up from his work, found that he was alone with his charge in the tent. He then saw the Afghans were in the midst of our men, and were plainly masters of the field. With true heroism, he determined to save the wounded man, if possible, and lifting him in his arms, he carried him in the open. A mob of camels and baggage animals was close by, and for this Dr. Roe made, hoping to place the man upon a spare camel. The Afghan cavalry were, however, too close, and they were quickly in the midst of the animals, cutting down the drivers, and looting the baggage. Dr. Roe dragged the soldier along, and by keeping in the thick of the press saved himself from the Afghans, who were soon too busily engaged with their looting to follow far in pursuit. Eventually he came upon the chaplain, and with his aid the wounded man was carried still farther away from the enemy. The soldier died in their arms, and they were forced to leave his body in order to provide for their own safety. Dr. Roe presently overtook his syce leading his horse away, the man having been told that his master had been killed. This good fortune, enabled the brave surgeon, already almost exhausted by his hard struggle, to overtake the brigade, then in full retreat. Is it too late to ask that some official recognition should be

made of the incident described above? The facts could be verified by the authorities.

### State Allowance to Soldiers' Families.

A ROYAL WARRANT has been issued which provides increased allowances to the families of soldiers who are separated from their wives by the emergencies of the service. Fourpence per day is allotted to the wife, and three halfpence to each child, per day during the separation of the husband from the wife, for the United Kingdom. If the soldier is ordered on active service the amount allowed is eightpence per day to the wife, and fourpence for each child.

This is as it ought to be; the tendency of the day is to discourage marriage in the ranks of the army as far as that can be done by "orders and regulations." Besides, soldiers who marry "with leave" and whose wives and children come within the provisions of the above warrant, there are others married without leave, and consequently not officially recognised, whose condition, at all times very wretched, becomes doubly so when their husbands are absent. These women often left as strangers at the port of embarkation without any means of subsistence speedily pass into pauperism or vice, disease too often follows, and thus our population of poor-houses and hospitals is added to, in the first instance by these women, in the next by their sickly and diseased offspring. As a measure of public health it is most desirable that their cause be taken up.

### The Health and Sanitary Work of Dublin.

THE report of the Dublin health for the month of April is remarkably favourable. The death-rate was only 31·78 per 1,000 of the population, which, for the second city in the empire, is a very happy state of things.

The deaths from the seven principal zymotic diseases numbered 41, being one under the previous month, 34 under February, and 71 under January, 1880. As compared with April, 1881, the comparison is very striking. Total deaths from zymotic diseases 134 in 1880, 63 in 1881; from the seven principal zymotics 168 in 1880, and 41 in 1881. In 1880 small-pox killed 22, and measles 21 persons, whilst in 1881, not a single death from either of these diseases was recorded. As the deaths from zymotic diseases which occurred in five weeks are recorded in the returns for April, the average weekly number of deaths from these diseases was only 13, the lowest probably ever recorded in Dublin.

The list of sanitary work done throughout the city affords promise of greater activity on the part of the Public Health Committee of the Corporation, stimulated no doubt by the Superintendent Medical Officer of Health, Dr. Cameron. We would be glad to be informed as to the reason for the apparent inactivity of the medical officers of health whose duty it is to report to the Public Health Committee the sanitary defects observed by them. Of these fifteen officers, four made within the month, no report at all, five made no more than two or three reports, and the most active of them all only made thirteen. Is this so because the Public Health Committee has been wont to ignore these reports and has thus discouraged the sending of them by the dispensary medical officers? or is it that the Corporation won't pay these gentlemen, and

therefore does not ask them to work? or is it that the medical officers themselves are neglectful and lazy? No doubt many of the sanitary defects which are detected by them are reported verbally or remedied upon their verbal advice, but we cannot regard this method of performing important sanitary work as either businesslike or effectual, and we say it is not creditable to the profession, and still less so to the Corporation, that medical or other officers should be encouraged or permitted systematically and habitually to neglect the duty for which they are paid, while so much remains to be done for the improvement of the health of the city.

### A New Oil.

OUR scientific contemporary, *Nature*, has the following as a "Note":—"A new medicinal oil has just been introduced into this country by Messrs. Burgoyne and Burdidge, the well-known chemists, of Coleman Street. It is known as Oolachian Oil, and is said to be scarcely distinguishable from cod-liver oil. It is obtained from a fish called by the North American Indians Oolachan, or candle fish, from the fact that when dried the fish itself can be used as a torch or candle, on account of the large quantity of oleaginous matter it contains. The fish is met with on the coasts of Vancouver's Island and British Columbia, and in the bays between the Frazer and Skuna rivers. Similar in its habits to the salmon, it ascends the rivers to spawn once a year, but remains only for a very short period, sometimes not more than a day, and as this is the only time they can be caught by the Indians, the manufacture of the oil is somewhat precarious. The fish itself, which is about the size of a herring, is much esteemed by the Indians, on account of its delicacy of flavour and valuable medicinal properties. In America the oil has already a great reputation as a valuable and efficient substitute for cod-liver oil, and there is every probability, as it becomes known in this country, of its taking a prominent place as an important medicine."

### Professor Gegenbaur.

THE well-known comparative anatomist, Professor Carl Gegenbaur, was recently declared to be dangerously ill, and the cause of his indisposition was said to have been blood-poisoning, contracted during dissection. With the announcement of his being on the way to recovery, this explanation of the attack is refuted, and the chief danger experienced was from erysipelas, for which no cause can be assigned. Peritonitis complicated the case, and for a time much anxiety was felt for the well-being of the illustrious patient. Much satisfaction will be generally felt that all danger is, by the physicians in attendance, considered to be past, and although convalescence will be a lengthened and tedious affair, there is every prospect that many years of labour are probably yet before the great anatomist.

### Colour Blindness.

THE subject of colour-blindness has been selected by Mr. Brudenell Carter as Cantor lecturer to the Society of Arts. Mr. Carter's course is the fifth and last of the present season, and will consist of three discourses, the first having been delivered on Monday last, the 16th

inst. The course includes a general sketch of the subject; description of the methods employed to test colour-blindness; its prevalence, the mistakes committed by those affected with the defect, and means taken to remedy it. A descriptive account of legislation, with a view to limit the accidents due to colour-blindness, will be given, and also an account of the chief industries in which it is attended with serious consequences.

### The Election of Council of the Irish College of Surgeons.

THIS election will take place on the first Monday in June. Mr. Baker, dental surgeon, of Dublin, and Dr. Edward H. Bennett, professor of surgery in the School of Physic, have declared themselves as candidates.

### Management of Infectious Cases.

THE adjourned discussion on Dr. Richardson's address, entitled, "Suggestions for the Management of cases of Small-Pox, and of other Infectious Diseases in the Metropolis and Large Towns," will take place to-day (Wednesday) in the Sanitary Institute, at 8 p.m. We recently gave a brief account of the paper originally read, and it may be expected that the discussion appointed for this evening will be an unusually instructive and important one. Since the last meeting was held, the subject of the paper has received especial prominence in connection with the rapid growth of small-pox infection, and this will doubtless be dwelt upon by the speakers.

### Soiree at South Kensington.

ON Friday last a numerous and distinguished company assembled at the South Kensington Museum in response to invitations issued by Dr. S. O. Habershon, as President of the Metropolitan Branch of the British Medical Association. The galleries of the Museum were brilliantly illuminated on the occasion, and concerts of vocal and instrumental music were specially arranged for the amusement of the guests, while a military band added much to the pleasure of promenading. The gathering was a brilliant success, and included, besides a large number of ladies and non-medical visitors, the chief members of the profession in London and around.

### The New Infirmary at Notting Hill.

WE understand that the gigantic Infirmary, which is to accommodate 600 sick-poor of the parish of Marylebone will be opened early in June by their Royal Highnesses the Prince and Princess of Wales. From a private inspection, the design is excellently adapted to requirements, and every modern sanitary improvement appear to have been well carried out by the builders, Messrs. Wall and Co. The Committee chosen from the Board of Guardians consists of six members, amongst whom are Mr. Boulnois, J.P., Chairman of the Board of Guardians, and Dr. J. McGrigor Croft, a gentleman well qualified by his military medical experience and position, to direct such an establishment. The appointments of medical superintendent, house-surgeon, assistant-surgeon, and dispenser, are at the decision of the Infirmary Board. There are the enormous number of 100

applicants for the principal medical post, 32 for assistant-surgeon, and 137 for dispenser, involving no light task and anxiety upon the Committee of Selection.

### The Population Returns.

THE quarterly return of births, marriages, and deaths for the quarter ending March, 1881, gives the following figure for the United Kingdom: Births, 288,168, deaths 188,603, the natural increase being thus 99,605. In England the death-rate did not exceed 21.8 per 1000 of the estimated population, and was 2.1 below the average rate in the ten preceding corresponding quarters. So low a death-rate in the first quarter of the year has not been recorded since that of 1856, when a similar rate prevailed.

The 138,582 deaths included 70,889 of males, and 67,693 of females; the annual death-rate among males was equal to 22.9, and among females to 20.7 per 1000 estimated to be living of each sex. In equal numbers living the deaths were as 111 of males to 100 of females; this proportion in the first quarter of 1880 was 110 to 100.

Naturally, the deaths in towns and cities were in greater number than in rural districts, the proportions being 23.3 and 19.6 respectively. This urban rate is somewhat in excess of that recorded in the last quarter of 1880.

In twenty of the largest English towns, including London, having an estimated population of about seven and a half millions of persons, the death-rate averaged only 23.8 per 1,000, against 25.2, 27.4, and 25.5, in the three preceding corresponding quarters. The lowest rates in the twenty towns last quarter were 19.5 in Leicester, 20.2 in Bradford, and 20.3 in Portsmouth; the rates ranged upwards in the other towns to 25.2 in Plymouth, 27.3 in Oldham, 29.3 in Liverpool, and 30.2 in Manchester. These wide differences were but to a slight extent due to variations of zymotic fatality. In fifty other English and Welsh town districts, with an estimated aggregate population of about three millions, the death-rate averaged only 22.5, and was 1.3 below the average rate in the twenty larger towns. Among these fifty towns the death-rate did not exceed 15.6 in South Shields, 16.1 in Reading, 16.7 in Cambridge, and 16.8 in Maidstone; the highest rates were 28.3 in Bury, 28.5 in Swansea, 29.1 in Blackburn, 32.5 in Stockport, 32.9 in Macclesfield, and 35.2 in Ashton-under-Lyne. The high rate in Swansea was mainly due to the epidemic fatality of scarlet fever and whooping-cough. Of the zymotics scarlet fever and whooping-cough were the most fatal, the numbers being 3,145, and 3,017. "Fever" is put down for 1661 deaths, diarrhoea 1,480, small-pox 730, and diphtheria 657. The rate from zymotics was 1.91 per 1,000, against 2.90, the average of the ten preceding corresponding quarters, and shows a very low percentage. Again, it is recorded that 4.6 per cent of the deaths were not certified, this being an increase on former returns, and in Wales, north and south, the percentage of uncertified deaths rise to the large figures of 12.1 and 13.7. The reasons for this, and for the variations in other places might well occupy the attention of the Registrar General.

### The International Medical Congress.

WE learn that the King and Queen's College of Physicians in Ireland has followed the example of the Royal College of Surgeons, having voted a grant of 30 guineas from the College funds towards the expenses of the International Medical Congress.

DR. W. H. MIDDLETON has been unanimously appointed visiting and consulting physician to the Mullingar Asylum, subject to the approval of the Lord Lieutenant.

THE will and codicil of Dr. William Hardwicke, coroner for Central Middlesex, recently deceased, were proved on the 19th ult., by Mr. Arden Hardwicke, the son, and Mr. J. W. Marchant, the executors, the personal estate being sworn under £4,000.

At the thirty-third anniversary festival of the City of London Hospital for Diseases of the Chest, held last week, donations to the amount of £2,050 were announced. It was stated that £9,000 were required to carry on the work of the institution on its present scale, and the annual subscriptions represented only £2,400 of this sum.

WE much regret to report the illness from typhoid fever of Dr. William Thornley Stoker, Professor of Anatomy in the Irish College of Surgeons. The first symptoms of the disease manifested themselves on last Monday week, and we are glad to learn that, so far, the progress of the disease has been favourable.

THE annual rates of mortality last week in the principal large towns of the United Kingdom per 1,000 of their populations were:—Brighton 12, Leicester 14, Sunderland 16, Birmingham 16, Oldham 16, Portsmouth 16, Salford 17, Bristol 17, Norwich 18, Bradford 19, Manchester 19, Sheffield 20, Newcastle-on-Tyne 20, Leeds 20, London 20, Plymouth 20, Edinburgh 20, Glasgow 21, Liverpool 22, Hull 23, Nottingham 24, Dublin 27, and Wolverhampton 28.

IN the principal large foreign cities, the mortality, according to the most recent weekly return, was in—Calcutta 34, Bombay 36, Madras 49; Paris 29; Geneva, 22; Brussels 24; Amsterdam 24, Rotterdam 24; The Hague 30; Copenhagen 24, Stockholm 25, Christiana 22; St. Petersburg 58; Berlin 24, Hamburg 26, Dresden 31, Breslau 32, Munich 44; Vienna 32; Buda-Pesth 40; Rome 28; Venice 23; Alexandria 46; New York 31, Brooklyn, 21, Philadelphia, 24, Baltimore, 19 per 1,000 of the population.

## Scotland.

(FROM OUR NORTHERN CORRESPONDENT.)

HEALTH OF EDINBURGH.—For the week ending with Saturday the 7th inst. 89 deaths occurred in Edinburgh, and the death-rate was 21 per 1,000 per annum. Only one death from fever was reported in the New Town. The southern suburbs still continue free from zymotic deaths.

DR. BELL'S INSTITUTION FOR DISEASES OF WOMEN AND CHILDREN.—The annual meeting of this institution was held in the Religious Institution Rooms, Glasgow, on the 10th inst. Mr. James Campbell, of Tillichewen presided, and was ably supported by the Rev. Albert Goodrich. We are always on tip-toe expectation for the amusement—the never-failing fun—annually derived now from the medical officer's report. It is invariably in the highest "flamfoozle" style, and on this occasion the literary merit is decidedly above the average. Dr. Bell states in his report that since the charity was organised it has been the means of palliating an incalculable amount of suffering, and of restoring to useful and active life, wives and mothers who were before martyrs to pain, and who were bowed down by weakness and unrest; and then the "incalculable amount of suffering" he proceeds to calculate with a refreshing simplicity. During the year 289 women had been patients in the institution. On an average, each woman had made fifteen visits to the institution, so that the number represented 4,335 consultations. Of this number 257 had been cured, 17 had been relieved, 9 had received advice which had not strictly come under the home treatment, and 6 had been dismissed as incurable. "Bowing down by unrest" may seem a puzzler to the most accomplished nosologist; but whatever it may mean, we have reason to thank a beneficent Providence that in the hands of Dr. Bell the affliction turns out of so signally curable a nature. We are not certain whether Dr. Bell has served a nosocomial apprenticeship in West Regent Street. We have culled but one flower from Dr. Bell's literary bouquet; we are certain it abounds in them, and the ardent student of "Belles Lettres," we are certain, could not do better than at once procure, at any cost, the Report of the Glasgow Institution for Diseases of Women and Children.

FEVER EPIDEMIC AT ST. VIGEAN'S, ARBROATH.—A meeting of the committee of the parochial board of St. Vigean's, being the local authority for the pariah under the Public Health Act, was held on Tuesday, the 10th inst., when a report on an epidemic of typhoid fever at Bridgeton of North Garry, St. Vigean's, was given by Dr. J. S. Crichton, the medical officer of health. It appeared that in the course of a few weeks there had been sixteen cases in the midst of a population of about fifty, and that only three families in the immediate district had escaped. There had been three cases also in a more distant part of the parish, and the persons affected had had communication with the infected district. Several deaths had occurred. The cause of the outbreak was supposed to be a well which had become polluted with surface water from highly manured fields, and which, Dr. Crichton suggested, might have contained the specific germs of typhoid fever. The water had been analysed, and was reported bad. It was proposed by the medical officer in his report that it should be conducted from the spring to the outflow in cast-iron pipes. The meeting concurred in this recommendation, and it was agreed to send a copy of the report to the proprietor of the place for his consideration.

THE COOMBE LECTURES.—The second lecture of this course was delivered on the 10th inst., in the Church of Scotland Training College, Edinburgh, to a crowded audience by Dr. Andrew Wilson. The lecturer began with a brief sketch of the actions and changes going on from day to day in the human body, with special reference to the action of the heart, and to the waste that was continually going on in proportion to the work done. Proceeding next to discuss what the body was composed of, he pointed out that there was not one element known in the human body

that was not found in the world outside. Protoplasm, which entered into the composition of every living thing under the sun, was made up of carbon, oxygen, hydrogen, and nitrogen, with traces of phosphorus and sulphur. They had not yet got any clue as to how life combined those substances to form protoplasm, though many compounds—such, for example, as urea—which had long been supposed to be manufactured by animals and plants alone, were now capable of being artificially made in the chemical laboratory. After observing that man had no type peculiar to himself, Dr. Wilson went on to describe, with the aid of a skeleton and diagrams, the structure of the body, especially the spine, exhibiting and classifying the various vertebrata, and referring in passing to the structure and composition of bone.

ROYAL COLLEGE OF SURGEONS, EDINBURGH.—At a meeting of the College on Monday last, the sum of £225 was duly ballotted for, and will be added to the funds of the College with all due solemnity. Of the nine gentlemen contributing the above sum, five are members of the London College. At a future meeting, £150 will be added from a like source, but on this occasion only two of the six gentlemen claiming the "Fellowship distinction" are licentiates of the Edinburgh College; the Glasgow Faculty, in this case, being the contributing body. The Edinburgh College has much to be thankful for. The above looks very much as if the Glasgow Faculty was good enough to enter the profession, but that the Edinburgh "Fellowship distinction" was a little better in the colour of its plumage.

WANTED A PORT-SANITARY AUTHORITY.—In a report on the Health of Edinburgh, laid before the Public Health Committee of that city on the 11th inst., Dr. Littlejohn stated that he had received a communication from the medical officer of health in Glasgow, that small-pox had broken out among some emigrants from the Continent who had landed at Leith, and passed across the country by rail, *en route* for America. It was resolved to communicate with the Government on this matter, with the view of having all emigrants from the Continent landing at British sea ports, examined by the local medical officer before being allowed to travel inland.

EXTRA MURAL MEDICAL SCHOOL, EDINBURGH.—The classes are now in full working order. For practical anatomy Mr. Symington has a class of about two hundred. Dr. Croom discourses on the principles and practice of midwifery at Minto House to over a hundred students, the greater bulk of whom are University students anxious to get some practical knowledge of their subject. The course does not qualify for the University, but the University course is delivered with so many oratorical irregularities that it is somewhat difficult to follow the speaker. The other classes are fairly well attended, Dr. Hamilton having between forty and fifty students in his practical pathology class. He suffers like the other lecturers from the fact that the University proposes to examine as well as teach, which always commands a class although the students may require to sit with ear trumpets to catch the words of the lecturer.

"STRATHAVEN FASTING GIRL."—Under threat of being sent to a lunatic asylum, this prodigy has reverted to the usual conditions of humanity, and, beginning with porridge and milk, now partakes freely of ordinary food. For some prurient people a purpose has been served. Large numbers were thus permitted to write on behalf of the interesting patient, and offer wise suggestions; amongst others, that the patient's bed should be placed directly north and south, in order that participation in telluric magnetism should be as free as possible! We think

the application of a bunch of fresh nettles to the gluteal region would have a much more beneficial effect.

THE GLASGOW DEATH-RATE.—The mortality in Glasgow for the week ending with Saturday, the 7th inst., was at the rate of 25 per 1,000 per annum, being a decrease of one as compared with the previous week. The death-rate in the corresponding week of 1880, 1879, and 1878, was equal to 29, 26, and 24 per 1,000 per annum of the population respectively. The death-rate of 1881 is made up according to the census returns, while the returns of previous years, were based upon the medical officer's estimate.

## Correspondence.

### NEW SCHEME OF EDUCATION AND EXAMINATION OF THE ROYAL COLLEGE OF SURGEONS, IRELAND.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In my letter of the 7th inst. I stated that the system formerly adopted by some students of "nominal study—idling and cramming"—could be pursued under the regulations suggested by the General Medical Council with the same impunity as before. Students who were so inclined could go in for the preliminary examination, get registered as medical students, then devote all their time for a year and three months to the washing of bottles, working behind the counters of a bank or haberdashery shop, or other less honourable or useful employment; then, entering for lectures and hospital practice but continuing to follow their former occupations or no occupations, they give as much time for a couple of years more, if industriously disposed, as their other pursuits will permit of, after which they grind and cram and prepare to run the gauntlet of the examination hall, when, if not detected, they emerge full-fledged doctors, and are entitled to be registered and appear before the public with the Government stamp testifying that they are fully educated, and conferring on them all the rights and privileges of "registered practitioners."

It requires but little experience among students to recognise the above as no fancy sketch. Honest, industrious, and conscientious men will thoroughly work out their studies under any system, but the idle and dissipated are led into temptation, and the ambitious, who are fired with the praiseworthy desire to advance themselves, are enabled to do so under false pretences, by the facilities afforded by the present system of entering the medical profession.

The only practical remedy for this state of things is to give the student work to do year by year, and see that he does it; and this is the key-note of the new educational scheme. A certain course of study is marked out for each year in such order as is thought most conducive to the attainment by the student of a sound and thorough knowledge of his business. At the end of the year he is examined in the year's work, and he must prove that he has sufficiently mastered it before being allowed to enter on further studies.

The system of sessional examinations has nothing new in it. In most Universities it is more or less fully adopted. The Irish College of Surgeons have been trying to introduce it for the last forty years, but have failed in their efforts because they did not make it complete and imperative.

The advantages of it, besides the foregoing, are numerous. I will mention some. 1st. The student is taught the order in which he should take up the subjects he has to study. 2nd. He is stimulated to study systematically and steadily. 3rd. Having proved that he has obtained a sufficient knowledge of certain subjects, he is allowed to pass on to a higher range, applying the knowledge gained of elementary subjects, without having his attention distracted by preparing for examinations in them. 4th. He pursues his studies step by step, and so does them more thoroughly. 5th. The sessional examination shows him whether he is working rightly, and in what he is deficient. 6th. It lightens his task, giving him his examination in stages, instead of concentrating all in one great critical examination, which is to prove the turning point of his destiny. 7th. It enables his parents and guardians to know whether he has been attend-

ing to his business or idling. 8th. If he should be unfit for the profession, this will be ascertained before his time and capital have been expended, and so he will be enabled to apply himself to some other pursuit.

I am, sir, yours, &c.,

May 14, 1881.

GEORGE H. KIDD.

[To the list of benefits likely to accrue from the proposed system of annual examinations Dr. Kidd might have added a ninth, which, though not directly conversant with education, would have immediate practical effect upon the student and his teaching, i.e., that the proposed system would compel his certificate to be taken out, and his fees paid once a year, and would thus put an end to the existing nefarious apprentice-farming or credit-fee system, under which the "farmer" appropriates the student's money for three years, and then, on the eve of examination, buys up a sheaf of certificates for courses which were never attended, or perhaps even entered for, from a lecturer who, having already given the required instruction, will be paid nothing for it unless he testifies to the "diligence" of the student, whom possibly he never saw. It is to be anticipated that the grinders and apprentice dealers, who are growing rapidly rich upon this disgraceful system, will do their best to decry the proposed reform, and will, with that view, disinter the worn-out argumentative bogie with which, for so many years, they have successfully frightened timid reformers in the Irish College of Surgeons. They will, no doubt, clamorously declare that repeated examinations and a strictly-enforced four years of study will drive away the great body of Irish students in one universal exodus to Glasgow and Edinburgh; that the Irish College of Surgeons will be speedily gazetted bankrupt; and, of course, that their warnings are solely animated by a love of the College, and a soul-stirring fear of its ultimate extinction. With those who are not acquainted with Irish students or Scotch colleges these statements may have force, but not with those who know that, as a matter of fact, Dublin students hardly ever go to Scotland for their diplomas, and that, if they did so, they would probably save themselves nothing in the way of examina-tional stringency; and we have no doubt that most sensible people will discount at its true value the new-born, [yet gushing, anxiety of the Dublin apprentice-farmer for the welfare of his beloved college.—ED. M. P. & C.]

## Literary Notes and Gossip.

DRS. HARVEY and DAVIDSON, of the Aberdeen University, have issued a new edition of their useful little "Syllabus of *Materia Medica*;" as, however, it is simply a reprint, we can add nothing by way of comment, to our former review.

PROFESSOR GRAINGER STEWART has issued, in pamphlet form, his interesting and instructive paper "On Paralysis of Hands and Feet from Disease of the Nerves," which appeared in the *Edinburgh Medical Journal* for April last.

PROFESSOR DE CHAUMONT'S lecture on "Sanitary Assurance," which was delivered at the London Institution in March, has been printed in pamphlet form, together with the speeches which followed from Mr. Erichsen, Sir Joseph Fayrer, and Mr. Brudenell Carter.

ANOTHER addition has been made to Churchill's manuals by the issue of Dr. W. H. Day's "Diseases of Children." A cursory glance has impressed us favourably, but we shall examine it critically anon. As several of the chapters have already appeared in the *Medical Press and Circular*, it could scarcely be other than a good book.

THE fourth edition of "Gaut's Guide to the Examinations,"

at the College of Surgeons of England, is a great improvement upon previous efforts. The various changes in the examinations, recently introduced at the College, are duly chronicled; the alterations and renumbering of the anatomical and physiological specimens in the museum noted, and the examination papers from 1869 to present date, given in systematic order. In fact, it may now be pronounced a "perfect guide."

THE new number of the *Journal of Psychological Medicine*, edited by Dr. Forbes Winslow, contains several very interesting articles, one on "Psychology in our Poets," bearing traces of the same facile hand that has contributed similar essays in former numbers. A very readable and suggestive little article on "The Mental Development of the Infant of To-day," is well worth reading, and likewise "The Causes of Insanity." The whole number is a good one in all respects.

To those of our readers who possess a garden, a little shilling work just issued by Messrs. Carter and Co., of High Holborn, London, entitled, "The Practical Gardener," edited by E. J. Beall, F.L.S., will be much appreciated at this season of the year. It is convenient in size, well-printed, and contains a large amount of information and instruction upon every-day matters connected with gardening, as well as illustrations of geometrical designs for elaborate carpet and other bedding.

THE "Index Medicus" has now started upon the third year of its existence, and though its past has entailed considerable pecuniary loss upon Mr. F. Leypoldt, of New York, its energetic publisher, he has such firm faith in the ultimate support of the profession, as to determine him to continue the publication for another year, in the hope that by the expiration of that time it may be placed upon a self-supporting basis, for which it requires only 200 additional subscribers. The work is so essential to students of medical literature, that we sincerely trust his confidence will be well repaid.

THE yearly volume of "House and Home," just issued, is largely filled with excellent advice and suggestions relating to domestic sanitation and hygiene, of a sufficiently practical nature to merit a very considerable degree of attention. The effort to improve the condition of our homes, had enough at the best, is a praiseworthy one, and deserves to be fully encouraged. The widespread perusal of such publications as "House and Home," is calculated to favour this end very completely, since the unpretending character of its essays brings them within the limits of even the most untrained comprehension. The work, moreover, contains a large number of ably written articles in biographical and other subjects of general interest, while the small price of the volume makes it easily accessible to all.

WE are informed that the great catalogue of books in the British Museum will, at the projected issue of five volumes a year, take forty years in completion. Altogether the catalogue is likely to comprise about three millions of titles, the total estimate for composition alone being roughly about £70,000. It has already been announced that the publication will commence with volumes specially devoted to certain subjects, or rather sub-headings, which have now become too voluminous for convenient handling in their present form. The catalogue when completed will be of great value and interest as a bibliographical work apart from its practical utility as a key to our great national library; but it is rather alarming to know that a single copy will cost subscribers £200.

KOPF, "On Diet and Hygiene," is the name of a little work (sixpence) before us, the perusal of which will smooth away many difficulties, and enable the reader the better to appreciate the all-absorbing question of which it treats. Parke, Pavy, Letheby, Thompson, and other authorities have been freely requisitioned; and the history of the various food products of, or into, this country from earliest times will afford valuable and instructive reading to all who take an interest in the subject. It has long been proven that we consume too much animal food in this country both for our health and our pockets, whilst soups, which are more nourishing, easier of assimilation, and cheaper, are frequently cast aside in summer time. These, and other matters are fully discussed within the fifty-six pages of "Kopf on Diet and Hygiene."

THE majority of the communications contained in the recently-issued volume (Vol. XII.) of "Transactions of the Institution of Civil Engineers of Ireland" are chiefly noticeable for a total absence of originality, and betray on the part of the writers a very superficial knowledge of the subjects they have attempted to deal with. Some rather eccentric papers of a semi-geological character offer suggestions relative to the form of sea walls, breakwaters, &c.; the author, however, could scarcely have been ignorant of the fact that the various phenomena he refers to had long before been observed and investigated. The discussion of one paper only, is published, and consists, for the most part, of a somewhat pretentious statement of facts and principles, familiar to every intelligent tyro in the profession. Of the few contributions possessing any merit, that on "Improvement in the Manufacture of Sulphuric Acid" displays considerable ability, originality, and mechanical skill.

A VALUABLE little pamphlet can be obtained from Mr. Newberry, the wholesale chemist, of 1 King Edward Street, E.C., entitled "Clinical Studies on Pepsical Peptones of Chapeaut." It contains histories of a number of cases in which the value of peptonised food is demonstrated by a narrative of the success attending its employment when the natural digestive powers are weakened, directly or indirectly, either in the organ, or in its secretions. The work is prefaced by an introduction descriptive of the general physiology of digestion, and the influence exerted on nutrition by the administration of peptones as food; a description of special peptone preparations is also added, and of the application of peptone to the cure of disease. There is much useful information in the *brochure*, and it cannot fail to afford important hints to practitioners who are perplexed by obstinate cases of non-assimilative indigestion. The importance of peptone foods has been well shown by recent inquiries, and the best forms in which to administer them is that especially of present interest, and is that which the pamphlet we call attention to, explains.

THE "Archives of Laryngology" has entered on its second volume, and deserves the attention of those to whom its contents are chiefly addressed. It is handsomely got up, and in every way worthy of the speciality it represents. The scope of the Archives embraces human and comparative morphology and physiology of the throat, and the pathology and therapeutics of throat diseases in the widest signification of the terms; but its conductors—wisely, we think—do not encumber their pages with contributions to otology, which has its own literature. Although the Archives is published in New York, its contents embrace so much that is of European origin, that it looks almost like an international production. It well represents Laryngology all over the world, and we wish it more success. The editors say they have enough material to produce six numbers a year, but we hope it will continue to be a quarterly, even if enlarged, for once a quarter seems to us often enough for a special journal of an almost international character.

NEW BOOKS AND NEW EDITIONS.—The following have been received for review since the publication of our last list, May 4th:—"On Anchylosis." By B. E. Brodhurst, F.R.C.S. (4th edit.) "Note-Book for Cases of Ovarian Tumours." By Spencer Wells, F.R.C.S. "Guide Medical à Contrexéville." Par le Dr. D'Estrées. "Clinical Studies on the Pepsical Peptones." By le Dr. Chapeaut. "Syllabus of Materia Medica." By Drs. Harvey and Davidson (5th edit.)

### MEDICAL REFORM.

At a meeting of the medical profession of Bradford and neighbourhood, held on May 5th inst., to consider the subject of medical reform, it was agreed to make the following recommendations:—

*1st Recommendation.*—"That this meeting recommends a one portal system of examination and admission to the medical profession for the whole kingdom, with various examining stations. The examiners should be appointed by the State. Say nineteen from the present examining bodies, six by the State, and six by the general body of the profession. That the qualification given shall be an all round one. Corporations still to give degrees when called upon."

*2nd Recommendation.*—"That preliminary examination be high, embracing as essentials, Latin (so as to read easy authors), Greek, so as to read the alphabet and look out roots in the dictionary. One foreign modern language also to be necessary. The above to be passed before the commencement of any medical studies whatever."

*3rd Recommendation.*—"Before commencing his more exclusively medical studies, the student should pass a second examination in physics, botany, natural history, and chemistry. A pupilage of at least twelve months with a qualified medical practitioner should also be required before obtaining his diploma or qualification to practise."

*4th Recommendation.*—"Medical curriculum to extend over three years after the above examinations have been passed."

*5th Recommendation.*—"Only duly qualified persons to practise as assistants."

### Medico-Parliamentary.

HOUSE OF COMMONS.—THURSDAY, MAY 17TH.

SMALL-POX IN LONDON.

MR. DODSON, President of the Local Government Board, in reply to Mr. W. H. Smith, said he was sorry to be obliged to state that the small-pox hospitals were full, or nearly so. He had no information as to persons affected lying in lodging houses in crowded districts, but he greatly feared such was the case. He had hoped that supplemental provision would have been made by the guardians and district boards, and to some extent this had been done, but he deeply regretted that in many cases the exertions made had been paralysed by the actual threat of legal proceedings. At the same time he was glad to be able to state that the Metropolitan Asylums Managers were exerting themselves to their utmost, and had provided on their own land accommodation for 300 or 400 convalescents, which would have the effect of relieving the hospitals to that extent. He would also add that the Local Government Board were exerting themselves to the fullest extent in respect to the making of further provisions.

### VACCINATION IN WORKHOUSES.

Mr. Dodson, in answer to Mr. Hopwood, said it was true that Dr. Stevens, one of the inspectors for St. Saviour's, Southwark, had recently suggested that all children born in the workhouse should be vaccinated before leaving; and that, subject to the opinion of the medical officer in any particular case, it should be done on the 6th day after birth. Dr. Stevens did not express any opinion of his own as to whether vaccination should be performed without the consent of the mother; but he did refer to an opinion of the Poor-law Board given as far back as 1848.—Mr. Hopwood asked the right hon. gentleman what his opinion was as to the law on the subject?—Mr. Dodson said his own opinion was that vaccination could not be enforced if the mother objected.

### Medical News.

Royal College of Physicians of London.—The following gentlemen were admitted Fellows of the College on May 16, 1881:—

John Wale Hicks, M.D. Lond., Sidney College, Cambridge.  
John Baptiste Potter, M.D. Ed., 20 George St., Hanover Sq., W.  
James Watt Black, M.D. Ed., 15 Clarges St., London, W.  
Francis de Havilland Hall, M.D. Lond., 46 Queen Anne St., W.  
William Ewart, M.B. Cantab., 28 Curzon St., W.  
David Bridge Lees, M.D. Cantab., 2 Thurloe House, S.W.  
Francis Charleswood Turner, M.D. Cantab., 15 Finsbury Sq., E.C.  
Joseph Ewart, M.D. St. Andrews, Brighton.

Royal College of Surgeons of England.—At the recent examinations of the Board of Examiners, the following candidates passed the primary examination in anatomy and physiology:—

Harry C. C. Shaw, Louis Robinson, Alexander Harper, Montagu Smith, Henry G. Wharry, Edgar W. Willett, Richard B. D. Burt, Herbert L. Downing, Charles O'B. Harding, Francis F. Walton, Arthur Hillaby, William R. de Morini, Stephen Paget, Constantin Spaekman, and Thomas Finch. St. Bartholomew's Hospital; Arthur E. Larking, Walter Fowler, Arthur H. Dodd, Charles S. Jago, Allan G. Minns, Herbert J. Dring, Edward W. Simmons, Henry T. Tressider, William H. Brenton, C. W. Creslock, Magnus M. Adler, and John H. H. Manley, Guy's Hospital; Thomas E. Gordon, Leonard J. Willan, William J. Best, Wilfred J. Hadley, Robert H. Nicholson, Edward H. Morgan, Daniel B. Spence, and Matthew G. Corner, London Hospital; Charles F. Clarke, William C. McDonnell, and Joseph J. W. Farr, Charing Cross Hospital; Thomas F. Foster, Nathaniel H. Turner, John H. Gostling, Charles L. Sanson, William Habgood, James T. Chivers, Herbert C. Dent, and Ernest Cusee, King's College; James A. J. Murray, Archibald McKenzie, Samuel G. Campbell, and Joseph J. Stapleton, Edin.; Thomas P. Gostling, John C. Jackson, Charles L. Lempreire, and James E. Blomfield, University College; Reginald M. Williams and Lewis D. Brown, St. Thomas's Hospital; Robert R. Williams, Glasgow and King's College; Gerald Callender and Arthur H. L. Stewart, St. Mary's Hospital; Jonathan Ruyston, Jose G. D'Arula, William Livermore, Philip B. Bentif, William D. Stevenson, and R. Mills, Middlesex Hospital; William Urwick, Westminster Hospital; Henry A. de Lom, Toronto and St. Thomas's Hospital; Laurie A. Lawrence, Henry F. Horne, and Frederick C. Wallis, St. Bartholomew's Hospital; William H. L. Mariner, Henry M. Sutton, and John L. W. Kitching, St. Thomas's Hospital; Owen W. Roberts, St. Mary's Hospital; Ernest J. G. B. rakey, Charing Cross Hospital; Charles D. Muspratt, Guy's Hospital; Thomas D. Richards, Edinburgh and King's College; Matthew R. Gooding, University College. H. H. Brown, Aberdeen, Thomas Birt, John F. Vinco, Edwin W. D. Kite, and H. Simms, Birmingham, John F. L. Whittingdale and Walter Dawson, Cambridge, Matthew Johnston, John T. Walker, Charles N. Benseley, Morris J. Williams, Francis J. Stevens, Alfred A. Lankester, William C. Dalley, Thomas Jones, Alfred D. Edginton, and James H. Mensies, St. Bartholomew's Hospital, Robert K. Peacock, Edinburgh, Edward H. Armitage, James C. Bates, Arthur C. Deare, Hugh Lamb, Francis Heathersly, George E. Stewart, and Alfred E. Taylor, Guy's Hospital, Edward Stewar, Middlesex Hospital, William Turnbull, James M. Robson, and Frederick W. Blackwood, Newcastle-on-Tyne, Robert C. Bruce, Edinburgh and Charing Cross Hospital, Richard A. Jackson, St. George's Hospital, Edwin Roberts, Leeds, John Williams, Liverpool, Cedwallier E. Evans, and F. W. Weir, Bristol, Thomas G. Farrott, and Edward S. Hasell, King's College, E. de C. Skeete, University College, L. P. Mumby, Westminster Hospital.

**Royal College of Physicians and Surgeons, Edinburgh.**  
**—Double Qualification.**—The following gentlemen passed their First Professional Examination during the April sittings of the examiners:—

Charles Walter Hemming, Gloucestershire, Lewis Gordon Lawson, Strathpey, Hugh Gough Haines, Bangalore, Horace Lynden Bell, county Cork, Walter Frederick Clark, Yorkshire, Louis Joseph Petrichev, Mauritius, John Nelms Hautin, Bristol, John Allen Carr, Bentham, Tom Bairston, Halifax, Walter Kinburne Harvey, Staffordshire, Robert Sinclair, Durhamshire, Arthur Kimberley Scattergood, Leeds, Alfred Evedley Taylor, Scarborough, Augustus William Thomas, Swaffham, Norfolk, Cyril John Williams, Yorkshire, John Joseph Mountain, Lincolnshire, Jeremiah O'Callaghan, Cork, Herbert Hartley, Yorkshire, John Francis Thomson, Linthgowshire, David Davies Roberts, South Wales, Fitzgerald Uniacke Anderson, Nova Scotia, Richard David Hartland, Cork, Walter Spencer, Bradford, Marcus William Alatson Kean, Whitby, Karl Wingvist, Hofva, Sweden, William John Sumner, London, Jam s Hilditch Bradshaw, Lancaster, John Smith, Coleraine, George Frederick Chadwick, Dewsbury, William Hawkins, Oswestry, John Rees, Carmarthen, Alfred Higginson, Lancashire, Francis James Power, Maidstone, John Small, Fife, William John Meharry, county Down, William Waddell, Ballymena, Thomas Hanson Smith, Keighley, Francis Edwin Mulliner, Northampton, Murdock Mackenzie, Stornaway, Philip Edmund Perot, Demerara, Arthur Nathaniel Barnley, Dunstable, Francis Joseph Salter, Leeds, Edmund Lewis Rour, York, Francis James Spilsbury, Devon, Harry Dugard Chapman, Staffordshire, Henry Horbury Preston, Manchester, John Clancy, Listowel, Anthony Bailey, Yorkshire, Thomas Patterson, Devlin, Belfast, Robert Farquharson Bowers, Bengal, William Patrick Kirwan, Galway, Edgar George Balield, London, Thomas Macdonnell Farr, Chatham, William Holberton Square, Kingsbridge, Edward Joseph Fernandez, Hong Kong.

And the following gentlemen passed their Final Examination and were admitted L.R.C.P. Edinburgh, and L.R.C.S. Edinburgh:—

James Booth Clarkson, Lancaster, James Daniel Ross, county Cork, William John Chibele, Nourse, Isle of Wight, Robert Webster, Australia, William Boulter Broadribb Parrin, Somersetshire, James Johnston, Dumfriesshire, Charles Swanson, Australia, David Carruthers, Dumfriesshire, James Arnott Hunter, Newcastle, Ontario, John Paulin Peel, Isle of Men, Frank Fraser, Portsmouth, Robert Roberts, Chester, George Daunt, county Cork, Thomas Henry, county Tyrone, John Philip Sullivan, Dublin, James Hilditch Bradshaw, Lancaster, John Dugdale Astley, East Langden, Dover, George William Macartney, Colombo, Ceylon, Francis James Power, Maidstone, Francis Harper Treharne, London, David William Johnston, Whitehaven, Richard Clegg, Burnley, John Gairford, Wexford, George Latham, Derby, William Abraham Dartnoll, Bochester, Titus Holden Harwood, Burnley, Henry Dobson Osborne, Londonderry, David Duncan Main, Kirkmichael, James Murdoch Cameron, Edinburgh, George Henry Ainley, Teddington, Charles Edward Watson, Herefordshire, Edwin Brunker Bayensdale, Lincoln, John Henry Dean, Sunderland, Frederick Francis German, Staffordshire, Thomas Hanson Smith, Keighley,

William Huey, Adelaide, S. Australia, Edmund James Armstrong Rogers, Ontario, Canada, David William Noble, county Leitrim, James Batterswaite, Lancashire, Charles Edward Lay, Suffolk, Isaac Kiddle, Surrey, Owen Frederick Beymour Evans, New South Wales, Eugene Joseph Geary, Cork, Isaac Holmes, Liverpool, Alexander Salvador Salbina Fernandez, India, Charles De Wolfe Heard, Prince Edward Island, Richard Ennes Delaney, county Mayo, Geoffrey McCarthy, county Kerry, George Thomas Webb, Poona, René Tubin Clément, Cape of Good Hope, Cornelius Maloney, county Limerick, John Murray, Aylth.

**Royal College of Surgeons, Edinburgh.**—The following gentlemen passed their First Professional Examination at the recent sittings of the examiners:—

Ernest James Flynn, Dublin, John Schofield, Bochedale, Kenneth Joseph Campbell, Yorkshire, Walter Stannes Snell, Plymouth, James Gurning, Castlere.

And the following gentlemen passed their Final Examination and were admitted Licentiate of the College:—

Allan MacLean, Lincolnshire, Robert McKensie Johnstone, Edinburgh, James Andrews, Glasgow, Alexander Mallagh, county Down, Michael Joseph Moyland, Galway.

The following gentlemen passed their First Professional Examination for the Licence in Dental Surgery of the College:—

Henry Wyles, Leeds, James Lindsay, Edinburgh, Edward James Aytton, Edinburgh, Frank Harrison, Sheffield, James Stewart, Perth, Thomas Gaddes, Carlisle, Joseph Smithson Thomson, Dublin, Hume Furdie, Alford, Robert Peel Thomson, Dublin.

And the following gentlemen passed their Final Examination and were admitted Licentiate in Dental Surgery:—

Frank Harrison, Sheffield, James Stewart, Perth, Thomas Gaddes, Carlisle, Edward James Aytton, Edinburgh, Maximilian Frank Simson, Lee, Kent, Hugh Fraser, Larga, Ayrshire, Henry Wyles, Leeds, Ernest Burt, Weymouth.

**Royal College of Surgeons in Ireland.**—At the April meeting of the Court of Examiners the undernamed gentlemen passed their Final Examination for the Letters Testimonial, and having taken the declaration and signed the roll were admitted Licentiate, viz:—

Howard W. Acheson, James A. Baird, Charles D. Barrett, John Brady, John G. W. Bullock, Richard Callan, John P. I. Coolican, Patrick I. Dempsey, John B. Dunlop, Frederick D. Elderton, John S. Galston, Walter Jones, Michael F. Kennis, Thomas W. Lewis, James C. MacMullen, John H. O'D. McGuinness, Gland H. Mac Swiney, Michael C. Moloney, Edmund Murphy, George Nellis, Augustus Nickson, Francis R. O'Brien, Joseph F. O'Carroll, Edward H. O'Doherty, Michael J. O'Doherty, John A. C. Penry, John A. Powell, Robert Power, James Quirke, Thomas O'G. Redmond, Alexander Ross, Ventry, A. J. Smith, Gones C. L. Stawell, Robert J. Tate, Macnamara M. Williamson, and Augustus W. Woodroffe, Esquires.

Eighteen candidates were rejected.

OVARIOTOMY AND PAROTITIS.

It is an established fact that orchitis and inflammation of the parotid may mutually complicate each other. Moreover there has been observed a relation between inflammation of the salivary gland in question, and that of the external genital organs and the ovaries. Facts in support of this opinion are found in the works of Bou-teiller, Meynet, Peter, and Billroth. Schroeder, who had never met parotitis as a complication of operations on the female genital organs, has just seen it as a sequel of five ovariectomies, two of which proved fatal (*Il Morgagni*). He comes to the conclusion that parotitis is a grave complication of gynaecological operations.

NOTICES TO CORRESPONDENTS.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a distinctive signature or initials, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

LOCAL REPORTS AND NEWS.—Correspondents desirous of drawing attention to these, are requested kindly to mark the newspapers when sending them to the Editor.

**READING CASES.**—Cloth board cases, gilt-lettered, containing 28 strings for holding each volume of the *Medical Press and Circular*, can now be had at either office of this Journal, price 2s. 6d. The postal regulations not allowing the Journal to be stitched, these cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

**DR. PEARSE (Plymouth).**—Your paper is marked for early insertion.

**A PROVINCIAL PRACTITIONER.**—We believe the system was first introduced by Dr. Burggræve, of Paris, some five or six years since. It is in moderate use in France, but has not found many adherents in this country, not so much from opposition as from want of knowledge and interest in the matter. In Spain the Dosimetric system is extensively in use, and so much importance is attached to the subject that an international congress is to be held in Madrid for four days next week for discussion on "The Dosimetric as compared with other methods for the treatment of Disease."

**DR. BERNARD.**—We hope in our next number.

**STATIST.**—May 14th, 1796, is the date usually ascribed to Jenner as that on which he satisfied himself of the value of vaccination against small-pox. In a letter to his friend Garduer he writes: "A boy of the name of Phipps was inoculated in the arm from a pustule on the hand of a young woman who was infected by her master's cows. Having never seen the disease but in its casual way before, that is, when communicated from the cow to the hand of the milker, I was astonished at the close resemblance of the pustules in some of their stages to the variculous pustules. The boy has since been inoculated for the small-pox, which, as I ventured to predict, produced no effect." Somehow the anti-vaccinators forget to print this information in their tracts of discovery.

**DIPSOSIS.**—The preparation is a private one by a chemist in London. We have tried the efficacy of the lozenges, but are doubtful whether they possess the advantages claimed for them. Thirst is not a local affection, but is systemic in nature, being, in all probability, due to deficient dilution of the blood. Consequently, nothing will permanently relieve it which does not introduce fresh fluid into the circulation. The lozenges excite the secretion of saliva, but as this must be drawn from the blood, there is no real relief to the constitutional feeling of thirst attending their use. The only cases in which they will be serviceable are those in which dryness of the throat and mouth excite a sensation of thirst.

**DR. CLARK.**—Many thanks, but the subject does not fall strictly within our sphere. You declare that it is political in nature, and as we have no concern with politics as politics, we must be excused from dealing further with it. The cases shall be attentively considered, and if it is decided to publish them, you shall have the proof copies you ask for.

**H. J. Q.**—See answer to Dr. Clark. Authors are always supplied with proof-slips of cases contributed by them to our columns, free of charge, if applied for.

**STUDENT.**—The M. B. examinations at Oxford are unusually late this year; the first, or scientific, will commence on Monday, June 27th. Names must be sent to the Regius Professor of Medicine, University Museum, Oxford, on or before May 30. The November examination is discontinued.

**DENTIST.**—There will probably be endless litigation before the question is decided. We certainly are of opinion that the dental profession has been very seriously injured in status by the admission into its ranks, on terms of equality, of the innumerable and undesirable persons possessed only of the most questionable qualifications to practise dentistry.

**DR. T. T. P.**—Your little essay on "Man, a Creature of Imitation," is full of sound common-sense philosophy, though hardly suitable for our columns.

**PROF. GRAINGER STEWART'S** courteous note has been duly received. We are much obliged.

**DR. ANGUS McDONALD (Edinburgh)** will please receive our thanks. The paper will have our best attention.

**M. D. GLASGOW.**—Our attention has already been directed to the report of the "Glasgow Institution for the Diseases of Women and Children." Reference to it will be found under our "Northern Correspondence." It certainly would be interesting to know what the "incurable" diseases were, which at an earlier period could have been cured by Dr. Bell. It does seem a pity that public support is not more lavishly bestowed on this Institution seeing the power to cure that is found therein. The wall over so much human suffering must touch the tenderest cords of every human bosom.

"**A DISPENSARY HACK**" will find the information he requires in the second edition of Ashby's "Notes on Physiology." According to Dr. Anstie, a healthy adult man should not consume daily more than from 1 ounce to 1½ ounces of absolute alcohol in whatever shape it is taken, i.e., dissolved in ardent spirits, wines, cider, and in malt liquors.

**S. M. O. B.**—We don't know the constituents of Eno's Fruit Salt, nor do we think it much matters. Fools will continue to buy such things, no matter what they are made of.

**DIAGENES.**—No letter is ever inserted without the name of the writer being known to the Editors. The subject to which your letter refers is now out of date and cannot well be re-opened.

**AMERICAN LATIN.**—The following is the text of an invitation to the New York Medical Club by Dr. H. D. Paine, of that city, which reaches us through the medium of *Harper's Weekly*:—

"**SCIENS, SOCIALITE, SOBRIETE.**"

**DOCTORES.**—Ducam nex mundi nite Panes; triticum at ait. Expecto meta fumen tu te & eta beta pl. Super attento, uno. Dux, hamor clata pati, sum parates, homine, ices, jam, etc. Sideror hoc. Anser.

"**FESTO REASONAN FLOAS SOLE.**"

**ASSOCIATION OF SURGEONS PRACTISING DENTAL SURGERY.**—Wednesday, May 18, at 7.45 p.m., Council Meeting.—8.30 p.m., Ordinary Meeting.

**SANITARY INSTITUTE OF GREAT BRITAIN.**—Wednesday, May 18, at 8 p.m., Dr. Richardson, "On Suggestions for the Management of Cases of Small-pox and of other Infectious Diseases in the Metropolis and large Towns."

**ROYAL INSTITUTION.**—Thursday, May 19, at 3 p.m., Prof. Tyndall, "On Magnetism."

**HARVEIAN SOCIETY.**—Thursday, May 19, at 8.30 p.m., Mr. J. Ernest Lane, "On Two Cases of Popliteal Aneurism."—Dr. G. C. Henderson, "On Cold Bathing in Acute Fevers."

#### VACANCIES.

**Birmingham, Queen's Hospital.**—Surgeon on the Staff. Applications to the Secretary before May 30.  
**Brompton Consumption Hospital.**—Assistant Physician. Honorary. Applications to the Secretary before May 25.  
**Castlebury Union.**—Medical Officer. Salary, £50, and £10 as Medical Officer of Health. Election, May 28.  
**Croydon General Hospital.**—House Surgeon. Salary commencing at £100, with board. Applications to the Hon. Sec before June 1.  
**Drogheda Union, Monasterboice Dispensary.**—Medical Officer. Salary, £110, and £20 as Medical Officer of Health. Election, May 31.  
**Liverpool Dispensaries.**—Assistant House Surgeon. Salary commencing at £108. Applications to the Secretary, 34 Moorfields, before May 28.  
**Royal Free Hospital.**—Ophthalmic Surgeon. Applications to be sent in before June 1. (See Advt.)  
**Middlesex Hospital.**—Ophthalmic Surgeon. Honorary. Applications to the Secretary by May 31.  
**North Eastern Hospital for Children, Hackney.**—House Surgeon. Salary, £70, with board. Applications to the Secretary before June 1.

#### APPOINTMENTS.

**ASHDOWN, G. W. W., M.B., C.M., M.R.C.S.E.,** Resident Surgeon to the Royal Maternity Hospital, Edinburgh  
**BOLTON, R. E. N., L.R.C.P.Ed., M.B.C.S.Eng.,** Medical Officer for the Baillickmoyler and Newtown Dispensary Districts Carlow Union.  
**BRIGGS, H., M.B., M.R.C.S.E.,** Resident Medical Officer to the Liverpool Royal Infirmary.  
**CLARKE, Mr. F. H.,** House Physician to the Western Infirmary, Glasgow.  
**DAVIDSON, Mr. A.,** House Physician to the Western Infirmary, Glasgow  
**DICKSON, Mr. G.,** House Surgeon to the Western Infirmary, Glasgow.  
**DOWNE, Mr. J. W.,** House Surgeon to the Western Infirmary, Glasgow.  
**FINCH, H., M.D., M.R.C.S.E.,** Medical Officer of Health for the Colchester Urban Sanitary District.  
**HUNT, Mr. J. M.,** House Surgeon to the Western Infirmary, Glasgow.  
**KER, Miss, L.M.,** Senior House Surgeon to the Hospital for Sick Children, Birmingham.  
**PORTFOS, R. B., M.D., C.M., L.R.C.S.E.,** Hon. Physician to the Blackburn and East Lancashire Infirmary.  
**PRICHARD, Mr. R.,** House Physician to the Western Infirmary, Glasgow.  
**RICHARDS, G., M.R.C.P.Ed., L.F.P.S.G.,** Medical Officer for the Second District and the Workhouse of the Ross Union.  
**ROBERTSON, E. W., M.B., C.M.,** Resident Assistant Physician to the Aberdeen Royal Infirmary.  
**SHIRRES, G., M.B., C.M.,** Resident Assistant Surgeon to the Aberdeen Royal Infirmary.  
**SMITH, J. M., M.B., C.M.,** House Physician to the Western Infirmary, Glasgow.  
**WATKINS, C. J., M.R.C.S.E.,** House Surgeon to the Glamorgan and Monmouthshire Infirmary.  
**WHITHEAD, H. R., F.R.C.S.E.,** Assistant Surgeon to the Charing Cross Hospital.

#### Births.

**FRASER.**—May 11, at 7 Lower Church Road, Weston-super-Mare, the wife of Graeme B. Fraser, Surgeon, of a son.  
**GIBBONS.**—May 12, at 88 Cadogan Place, London, S.W., the wife of R. A. Gibbons, M.D., of a son.  
**JAMISON.**—May 11, at St. Helen's, Lancashire, the wife of Arthur Jamison, M.D., of a daughter.  
**NEWTON-CLARE.**—May 13, at 2 Priory Villas, Calne, Wilts, the wife of E. Newton-Clare, M.R.C.S.E., of a son.

#### Marriages.

**ALLEN—MAW.**—May 11, at St. Ann's Church, Bishop Auckland, Richard G. Allen, M.R.C.S., L.R.C.P., of Belper, to Annie Blythe Maw, of Bishop Auckland, co. Durham.

#### Deaths.

**CARR.**—Feb. 12, at Machinga, Central Africa, of tetanus, W. Ward Carr, M.D. Lond., formerly of Lee, Kent, aged 31, eldest son of the late William Carr, M.D., of Lee.  
**JENNINGS.**—May 7, at 3 Castle Avenue, Clontarf, J. B. Jennings, L.K.Q.C.P.L., L.R.C.S.I., late of Hull, aged 29, youngest son of D. C. Jennings, County Inspector of Dublin.  
**SANDWITH.**—May 16, at 29 Avenue Friedland, Paris, Humphry Sandwith, M.D., C.B., D.C.L., aged 63.  
**SHERLOCK.**—May 13, at Powyke, Worcester, after a short illness, James Sherlock, M.D., for 27 years Medical Superintendent of the Worcester County Lunatic Asylum, aged 63.

### CLINICAL LECTURE

#### ON THE DIFFERENTIAL DIAGNOSIS BETWEEN CERTAIN HYSTERICAL CONDITIONS AND MYELITIS.

Delivered at the National Hospital for the Paralyzed and Epileptic.

By THOMAS BUZZARD, M.D., F.R.C.P.

GENTLEMEN,—The subject of nervous mimicry of organic disease in general has been, as you are well aware, admirably discussed by Sir James Paget. It is not my intention to take up your time by attempts to add anything of importance on the general question to the account which we owe to one whose unrivalled experience has been recorded with consummate literary skill. But I wish to bring before you to-day some cases of recent occurrence to illustrate the difficulties which often occur in distinguishing between certain forms of acute and chronic myelitis, and hysterical imitations of the symptoms belonging to such conditions. Opportunity will thus be given me for referring to points of diagnosis that may assist in preserving us from errors which are of very frequent occurrence. I may say at once that it is often extremely difficult, and occasionally for a long time impossible, to arrive at a confident opinion in cases of this kind. Yet, unless we can do so, should the case be one of hysteria, we stand little or no chance of curing our patient, and for obvious reasons it is a still more serious matter if we mistake a case of organic disease of the spinal cord for one of hysteria.

But, first, let me mention the forms of disease which, according to my observation, are the most likely to be confounded with hysteria, and I will here refer to Grasset's classification, which I have already introduced to you on a previous occasion. (a) On the side of systematic myelitis there is first spastic spinal paralysis from sclerosis of the lateral columns of the cord, and next acute anterior poliomyelitis, that affection of the anterior cornua upon which I

lectured last week. In my experience *tabes dorsalis* is rarely or never imitated by hysteria. I certainly did see not long ago a lady in whom a complete and temporary loss of the muscular sense in the lower extremities imitated one of the symptoms of locomotor ataxia, and produced a slight inco-ordination in the gait, but the diagnosis was easy owing to the entire absence of any corroborative symptoms. On the side of *diffuse myelitis*—*i.e.*, myelitis invading without distinction any or all of the regions of the cord,—two forms alone need special reference. Of the first, a circumscribed and subacute variety (most often, perhaps, when it attacks the dorso-lumbar region); of the second, that special form which we know as insular or disseminated cerebro-spinal sclerosis. Of this last I shall only say now that it is as regards this form of myelitis, and its imitation by hysteria, according to what I have seen, that an insuperable difficulty of diagnosis is very apt to occur. I propose to reserve this important variety for consideration in a future lecture. On the present occasion I shall refer to cases in which subacute myelitis, anterior polio-myelitis, and lateral sclerosis come in question.

The first case to which I shall draw your attention is that of a school girl, *æt.* 14, who was admitted into this hospital early last summer. She had never suffered from scarlet-fever or rheumatism, and there had been no phthisis in the family, nor was there any neurotic history. The catamenia had been regular. At twelve years of age she was one day leaning out of an open window, when a child at a window above let some water fall, in play, upon her head, and it struck her behind the right ear. She was much shocked, and all that night suffered from ear-ache. For some weeks after this she continued to go to school, but constantly complained of ear-ache and head-ache, and it was noticed that she was gradually becoming deaf. About three months after the occurrence she is described as having become childish and delirious, and rapidly losing her sight, hearing, taste, and smell. The sight was observed to fail first. It is said that she had quite an idiotic laugh. She continued to be "delirious" for a week. Then she suffered from very severe pain all over her, especially in the head. The pain is said to have been very intense in her ankles, and her mother says that "her ankles seemed to be dislocated" from the drawing of her legs. Then she had twitchings of the legs of such violence that they were thrown high in the air. The twitchings were not, it seems, confined to the legs, but the right arm and left shoulder were similarly affected.

(a) Vide *Medical Press and Circular*, January 26th, 1881.

There was also (from the description) some opisthotonos. The twitchings continued for two or three months.

The sight returned quite suddenly; "a flash seemed to pass before her eyes, and she recovered her sight," and with this improvement the spasms also became less. Then the hearing returned, and the spasms ceased.

Seven or eight months after the onset of her illness, she got into the state which she presented when admitted here, and she had remained in this condition for a whole year before she came to us. During the whole of her illness her general health, according to her mother's account, had been very good.

On admission here, the following report of her condition was taken by Mr. Broster, the then resident medical officer. She is a well-nourished and healthy-looking girl, who sleeps well, and does not suffer from head-ache or giddiness. Her hearing, sight, taste, and smell, are all normal. There is no want of symmetry in the face. The pupils, which are somewhat large, react to light. The upper limbs are well-nourished, and the cutaneous sensibility is normal. There is no pain, stiffness, or tenderness of the spinal column.

As regards the lower limbs, the patient says that she is unable to stand without support. She cannot walk, but with a stick in one hand, and leaning upon some one, she is able to "spring." This, indeed, is the way in which she gets upstairs; and her mother says that she is able to spring up three stairs at a time. She lies in bed with her legs extended, her ankles and feet tied together. In this particular position she avers that she is quite comfortable. She is able to flex the hip and knee-joints with as much force as ever she could in her life, and she can also readily flex and extend the ankle-joints, and move her toes freely. The cutaneous sensibility of the legs is perfect.

If one unties the bandage by which the ankles are fastened together, there is sudden and immediate adduction of the knees, with some rotation inwards of each lower extremity. This is accompanied by enormous rigidity of the anterior and internal muscles of the thighs. By the action the ankles are at once thrown apart, and the feet (each pointed strongly inwards) are crossed and locked rigidly one over the other. As all this happens she cries out and complains of great pain. The knees are so firmly locked together that it appears surprising that the portions of skin in apposition are not sore.

The muscles of the lower extremities react normally to the induced current. There is excess of patellar reflex on each side, and ankle clonus.

For five days the muscles of the thighs and legs were faradised with the strongest currents, whilst the feet were untied. A very slight relaxation of the rigidity was produced, whilst the current was being applied, but the effect was altogether temporary; the limbs instantly resumed the rigidly locked position when the application ceased. So strongly adducted were the limbs that, with my utmost force, I could not separate them. Placed on her feet, with the ligature removed, she was quite unable to stand, and sunk "in a heap" to the ground. To judge by the expression of her face and her tears, the rigid position which the legs assumed when unfastened, caused her great pain.

After being six days in the hospital, she was placed under the influence of ether, and as she became insensible, the muscles of the legs were felt to relax. She was then allowed to recover, but consciousness had not apparently completely returned, when the legs resumed, with extreme suddenness, their rigidly adducted and rotated position. We noticed, however, that they were now not so rigid as before. On regaining a certain amount of consciousness (being still intoxicated with the ether), she was induced to stand with help, and to walk, although feebly and clumsily.

She was now once more placed under the influence of the ether, and with the result of producing the same complete relaxation of muscles. This time she was more deeply anaesthetised, and before being permitted to recover the legs were abducted and rotated outwards and held in that position. As she recovered consciousness the legs did not resume their rigidity, and the girl expressed unbounded delight when she knew the position of her limbs. The left foot was perfectly straight, but there was a little inversion of the right foot when left to itself.

Ankle clonus could be obtained easily on the right side, but it was not of quite so prolonged and strongly marked a character as in spastic paraplegia. It was present though to

less degree on the left side. This time, whilst recovering from the ether, she vomited profusely. During the first application she was under the influence of ether for two minutes, and for five minutes during the second. The quantity of ether used was one ounce.

Next day we found there had been no return of rigidity, but there was an indisposition to walk. The ether apparatus having been sent for, she improved considerably.

On the following day she walked as well as ever, and two days later walked to church and stood at appropriate times during the service.

A week after the etherisation an endeavour was made to induce an ankle clonus, but without success in either foot.

She was discharged quite well within a fortnight of her admission. I learned a few days since that she has since continued in perfect health.

We had the advantage here of a complete history, and the diagnosis was easy. But I can quite understand that during the progress of this case there must have been difficulty especially in excluding cerebral and probably spinal meningitis, and that the rigidity with exaggerated reflex would have a *prima facie* resemblance to that arising from sclerosis of the lateral columns secondary to a lesion of the cord. But the course of the disease—the opisthotonos followed by sudden return of sight—was conclusive of hysteria. Moreover, had the rigidity depended on bilateral sclerosis, the jumping feats would have been absolutely impossible. Now, this girl recovered rapidly because we were absolutely sure of our diagnosis. You cannot cure a case of hysteria so long as you have any serious doubts about its nature.

On the other hand, I think that if you are able to be quite certain on this point and are prepared to act with sufficient energy, there are few cases that will not yield to treatment. The kind of treatment does not appear to be of so much consequence as its impressiveness. I feel sure that many of the cases which recover under the hand of the bone-setter are really cases of hysteria, which are cured by the administration of the anaesthetic, as this girl was cured. The Faradaic current is a very potent means of treatment in hysteria. A year or two ago a young lady whom I had seen on two or three occasions in the country with her medical attendant was sent up to town by him into lodgings near me in order to be under my observation. She had been for some weeks affected with periodical attacks of dyspnoea, the peculiarity of which was that they were of daily occurrence and commenced precisely at the same hour every morning. The morning after she had taken up her residence in town I was sent for to see her in one of the attacks and arrived within a few minutes of its commencement. I will read you the notes which I took at the time:—She is sitting up in bed, the eyelids closed, the hands down by her hips, clenched, the thumbs inwards, the muscles of the arms rigid.

There is a noisily drawn inspiration followed by expiration, which is very loud and hoarse, constituting a kind of extremely noisy harsh cough. This is followed by a series of short expiratory catches. The mouth is fixed unduly open, and mucus and saliva flow from it, and sometimes from the nostrils. During inspiration she raises her trunk to the perpendicular. During expiration she bends forward, so that her face nearly touches the bed-clothes. If she is touched during the attack, she shows impatience and turns suddenly away. There is general rigidity of the muscles of the trunk and extremities. The larynx is fixed. When I forced the eyelids open (for the orbicularis palpebrarum participated in the general rigid contraction of muscles, and the eyes were thus kept closed), I found the eye-balls turned upwards and inwards. The feet were in over-extension.

When the attack was over (it lasted some twenty minutes) I noticed that she seemed heavy and as though just awake, though scarcely aroused from sleep. Her face (naturally an intelligent one) was expressionless. A little later, when I obtained answers to questions she said that there was a feeling of pins and needles, which she felt during the attack, and which did not pass away immediately after its cessation. "During the attack," she said "she could not have got up and run away to save her life, if for example the house had been on fire."

I sent an induced current machine to the house, and next morning, when the attack commenced at 8.25, the regular hour, I was able to lose no time in applying electricity. The machine was arranged for its full strength. I placed one wetted rheophore on the neck over the larynx, and the other was then swiftly introduced within her open mouth.

The shock was very severe, there was a wild shrinking away, and an attempted scream, but it was some few minutes before repetitions of the painful application asserted their power, and the spasms gradually ceased, having, on this occasion occupied less than half their usual time. Next morning I took the precaution of arriving in her room at 8.20. After five minutes she had raised herself in bed, and the attack was commencing when the electrical application was swiftly called into action and she recovered in two or three minutes. On the following day I adopted the same plan of visiting her before the time, and it was then sufficient to show her the battery. She never had another attack, and has never suffered from hysterics since—now more than two years.

(To be continued.)

#### RAINFALL AND CLIMATE IN INDIA. (a)

By Sir JOSEPH FAYRER, K. C. S. I., M. D., F. R. C. P. Lond.,  
F. R. S., & c.,  
Hon. Physician to Her Majesty the Queen, and H. R. H. the  
Prince of Wales.

As introductory to the meteorological question, the geographical and physical features of India were described. The origin of rain, the theories of winds, more especially the trade winds and monsoons, were successively detailed. India, it was observed, presents in its different parts extreme modifications of climate and geographical features. The periodic variations of temperature, vapour, tension, and pressure, both annual and diurnal, are strongly marked and regular. As regards climate, India may be divided into—1. Himalayan; 2. Hindostan; 3. Southern India, or the Deccan. The rainfall varies according to latitude, elevation, and physical characters of the country. The effects of a dry or damp atmosphere at the same temperature are very different; dry air at a high temperature in motion is more tolerable than stagnant air loaded with moisture; the hot dry winds of Northern India more endurable than the cooler but saturated atmosphere of Lower Bengal or parts of Southern India. The seasons in India the hot are the rainy and the cold. The south-west monsoon commences with storms of thunder and wind; it bursts upon the Malabar coast in May, reaching places farther north later in the season, its force being expended ere it reaches the twenty-fifth of north latitude. The rainfall which attends this monsoon varies greatly, from 1.92 inches at Kurrahee, to 600 inches at Cherra Poonjee. The north-east monsoon commences in October. It is attended with dry weather throughout the peninsula generally, but on the Coromandel coast by rain till December, dry weather then till March, by variable winds and great heat till the end of May or beginning of June. When the south-west wind again sets in, first as what are called the lesser, and then by the regular rains of that season. At the hill stations generally, their elevation 5,000 to 7,000 feet, the climate is genial, the rainfall moderate, healthy in summer, bracing in winter.

In India there are areas of rainfall of various degrees of form and extent; these correspond to latitude, physical characters of the country, and proximity to sea or hills. The desert of the Thar is to a great extent rainless; in Scinde and part of the Punjab is under 15 inches; on the north and east is a zone, including Delhi and Agra, 100 miles wide, in which the fall is 15 to 30 inches; in the upper parts of the valley of the Ganges, Central India, and eastern parts of the Madras Presidency 30 to 60 inches. A southern dry zone extends from Nasick to Cape Comorin. The deltas of the Ganges and Mahanuddee, and lower part of the Gangetic valley, have a rainfall of 60 to 78 inches. There are two belts of excessive rainfall, one along the coast of Arracan, from the Irrawaddy to the Brahmapootra, the other on the west coast, from Cape Comorin to the Taptee, from sea shore to the top of the Ghâts. As in Britain the greatest condensation occurs at an elevation of 2,000 feet, so in the Khasia hills it takes place at 4,000 feet above the sea. At Mahabuleshwur, in the western Ghâts, conditions are somewhat similar, except that there the rainfall is about 300 inches. The heavy rainfalls at both these places, due to the south-east monsoon, presents an analogy to the heavy rains

on Ben Lomond, Glengyle, and the Cumberland hills, the result of warm moist air from the Atlantic and Gulf Stream. With regard to the influence of the solar spots on cyclical changes that involve recurrence of dry seasons, and consequent scarcity or famine, no very definite conclusions have been reached as to their value as causative agencies. The question of these spots in relation to rainfall is as yet a *questio vexata*.

The following are the conclusions quoted as to relations between climate and epidemics in India:—

1. Epidemic cholera is increased in intensity by continued dryness, evaporation, and high temperature; heavy rain will greatly diminish or wash it away.
2. Dryness, heat, and rapid evaporation reduce the intensity of fevers. After heavy rain, when the process of drying up begins, fever augments until the evaporation reaches a certain intensity, when it declines. In some places fever declines very much when the country is completely flooded, but increases in intensity when the rain ceases, and drying up begins.
3. Small-pox does not appear to be related to rainfall. It augments with increase of heat, and so continues till colder weather sets in, irrespective of the amount of rain.
4. Rain, with cold and high temperature range, appears to augment the liability to bowel diseases, but not to a considerable extent.

#### REMINISCENCES IN MIDWIFERY PRACTICE.

By M. C. BERNARD, M.B. Dub. Univ., L.R.C.S.I., & c.,  
Formerly Medical Officer to the Dundrum Dispensary  
District, Co. Dublin.

BEFORE the Medical Charities Act was passed in the year 1851, there were few qualified midwives attached to the dispensary districts throughout Ireland. In the district to which I was attached, the poor women, during the time of labour, were generally attended by ignorant old women, who either interfered unnecessarily or let nature take its course, when, however, imminent danger arose, the doctor was sent for in all haste. Under such circumstances I have often had most trying cases to treat, and had always to act on my own responsibility, as even during serious midwifery operations it would have been difficult to obtain the assistance of another practitioner. I was more frequently sent for in cases of retained placenta than from any other cause. The practice of the midwives at that period, when there was any delay in the expulsion of the placenta, was to place the patient sitting upright over a vessel of warm water, and whilst in this position the umbilical cord was pulled with force. Sometimes, by these means, the placenta was expelled, if not, the patient was put into bed again and the cord carefully tied with a string to the woman's thigh, lest it might return again into the uterus. I was sent for on one occasion, where the placenta remained in the uterus upwards of four days after the birth of the child, I at once introduced the hand and extracted it, as a matter of course it was in a state of decomposition, the stench was overpowering; we had little knowledge of the antiseptic treatment in those days, yet the woman recovered perfectly, without any of the results of blood poisoning, such as pyæmia, septicæmia, &c. Such a case occurring now-a-days would be sedulously treated with antiseptic injections and quinine.

I was sent for in another case, which although it occurred nearly forty years ago, the particulars are as indelibly imprinted on my mind, as if they were occurrences of recent date. I was called out of bed early on a summer morning to see a poor woman, whom the messenger told me was in a state of great danger after her confinement; she lived about three miles from my residence; when I arrived at the cabin in which she lived, I found my patient lying in bed in a state of syncope, almost pulseless, with cold extremities, I ascertained that she was confined of a living child about four hours before my visit, and that the placenta was retained. I had first some spirits and water given to her, which she swallowed with difficulty. I then made an examination and found that, although she was in a state of exhaustion, blood was trickling from the uterus.

(a) Abstract of a Lecture delivered before the Victoria Philosophical Institute, Adelphi, London, May 16th, 1881.

I immediately introduced my hand, and gently extracted the placenta, desiring one of the women at the same time to make pressure on the uterus. After the operation, the hæmorrhage immediately ceased, and the poor woman gradually recovered. I am aware that this practice is different from that laid down by authors, who for the most part recommend that the doctor should wait till the patient recovers from the state of syncope, before he interferes to remove the placenta, but as in this case the hæmorrhage continued uncontrolled by the state of syncope, I thought it better to act at once, as I considered that waiting for the woman to rally under these peculiar circumstances would be only waiting for her death.

I was more frequently sent for in cases of hour-glass contraction of the uterus than from any other cause. I have no doubt that in the majority of these cases, spasmodic contraction of the uterus was caused by the neglect of pressing on the fundus uteri immediately after the birth of the child, as well as by the malpractice adopted in these cases by the ignorant midwives. When called on to treat those cases, especially if hæmorrhage accompanied the retention of the placenta, I generally without any delay introduced the hand and arm into the uterus, and I have always found from the experience gained in operating in a great number of cases of this kind, that if the operation is done slowly, deliberately, and coolly, it is perfectly safe and without danger to the patient; the mode of performing the operation is well described in all standard works on midwifery. I have only to add, when you have gently worked your hand in the form of a cone through the spasmodic contraction of the uterus, which had divided the organ into two chambers you find at once your hand in the upper chamber, which often extends to the epigastric region—it is at this period in particular that the practitioner's presence of mind is required, the placenta being attached to the uterine walls, he must slowly introduce his fingers between the placenta and the uterine walls and gently peel off the placenta; when this is accomplished, the uterus will suddenly contract, expelling the placenta and the practitioner's hand simultaneously. To some it may appear scarcely credible that I should have met with so many cases of retained placenta, but I am certain that many medical men who have had the charge of dispensary districts before the passing of the Medical Charities Act can corroborate the accuracy of my statements. But I am happy to say, that such cases are seldom met with at the present day, as there are well educated midwives appointed to almost all the dispensary districts throughout Ireland.

A case of retained placenta with flooding, occurred when I was a pupil attending the Dublin Lying-in Hospital in Brittain street, the facts of the case are so vividly imprinted on my mind, that although I have no notes to consult, I can vouch for the accuracy of its most prominent details. Whilst on duty, together with other pupils, in the wards of the hospital, a young woman had a natural confinement, the child was born alive, there was not anything unusual in the progress of the case till after the child's birth, then hæmorrhage set in. According to the rules of the Hospital which existed at that time, the Master, the late Dr. Robert Collins and his two assistants, the late Dr. Jonathan Labatt and the late Dr. William O. B. Adams were quickly summoned to attend the case, the placenta was in the first instance extracted, and pressure made on the fundus uteri, the flooding however continued, the poor woman passed from one attack of syncope to another, tossing her arms about in extreme restlessness, until in about half an hour from the birth of the child, she ceased to breathe. All was done by those eminent accoucheurs to stay the hæmorrhage, the poor patient was supplied liberally with brandy, whether she got ergot or not I do not recollect, but buckets of cold water were poured from a height over the naked abdomen until both the bedding and flooring of the room were inundated with blood and water. Great progress has been made in the treatment of such fearful cases during the last few years. It is more than probable had the treatment recommended by Dr. Lombe Atthill been adopted in this case, either by cold or hot water injections into the uterine

cavity, the patient's life might have been saved, the liq. ferri perchlor. diluted with water has also been recommended by the same gentleman, although its use is not unattended with danger; as a last resource the transfusion of blood conducted by a skilful hand may ward off the fatal result.

I will mention another case which came to a successful termination, aided by the treatment recommended by Dr. Atthill. I was engaged to attend a lady, whom I had attended in five or six confinements on former occasions. When sent for, I was told by the nurse-tender on my arrival, that all was right, that the child was born, and that the placenta had come away. The nurse-tender was dressing baby, quite regardless of her patient, who was in a most perilous state. I went over to the bedside to see the lady, and, to my astonishment, found her in a state of syncope. Upon examination, I found there was profuse flooding. Having given her brandy, and desired the nurse-tender to press on the uterus, I quickly introduced the long tube into the uterine cavity, and with a syringe, injected a quantity of cold spring water. Its effects were instantaneous; the uterus contracted at once into a firm ball, and the hæmorrhage ceased. Had the cold water failed, I was prepared to have injected a solution of the liq. ferri perchlor., but, happily, it was not required. These two cases are of absorbing interest, as they clearly portray the modes of treatment adopted during the older times and the present period. They point out the vast improvements which have been made during the last quarter of a century in midwifery practice, and to Dr. Atthill, in particular, the credit is due for introducing this mode of treatment to the notice of his professional brethren. I have no doubt, had I not quickly adopted this method of injecting the uterine cavity, I would have lost my patient.

Before speaking of the mode of application of the forceps in tedious labour, I may state, that as a rule, I have seldom used chloroform during the progress of natural labour, but when the first stage became tedious, I have occasionally found it beneficial in hastening the dilatation of the os uteri. The medical practitioner must, however, be on his guard, when asked by a patient to administer chloroform by inhalation during labour. The following case may serve as an example of the difficulties he may have to encounter. I was sent for by a lady some years ago: she told me she expected her confinement at a certain date, and was anxious to know if I was in the habit of administering chloroform, as she gave me to understand that during her last confinement with her second child, the doctor, who attended her, used it nearly throughout the whole course of her labour. I told her that I did not approve of its use, except where it was absolutely necessary to relieve symptoms, or assuage continuous pain. When labour set in, I was again sent for by this lady. During part of the first stage, she remained tranquil enough, but as labour advanced, and when the pains became more severe, she cried out for the chloroform. I administered it in a teacup, after the method recommended by Dr. Braithwaite, the edge of the cup being allowed to rest under the lower lip, in order that there should be a sufficient admixture of atmospheric air during inhalation. From this time she continued to ask for the chloroform incessantly; as soon as one portion of the chloroform in the cup became evaporated, she quickly demanded more, and was quite disappointed unless anæsthesia was quickly produced. Every time she recovered from this state of insensibility, she imperatively demanded a further supply, and when refused—for I thought it only right to withhold my sanction—she got into a most excited state. I endeavoured to explain to her the great injury which might arise from continuance of the inhalation. The more, however, I reasoned with her, the more determined and excited she became, until, at last, she became most violent, hysterical, and almost maniacal. Fearing the consequences of this outburst of passion and violence, I had to yield to her caprices, and allow the uninterrupted continuance of the inhalation until the child was born. She ultimately got well after a slow convalescence. I may here state that

this lady had a large bottle of chloroform in the house, being determined in the event of my supply failing, to have sufficient to keep her under the influence of the drug until her troubles were over.

I have been frequently sent for by the midwife in cases of tedious labour; it was the usual custom of those nurses to trust altogether to Nature's efforts. I have, on that account, been in the habit of impressing on their minds the necessity of sending for me immediately, when the pains would appear to be inefficient. When I was a pupil in the Dublin Lying-in Hospital during the mastership of the late Dr. Robert Collins, the rule of practice in cases of tedious labour was to wait for several hours after the pains proved inefficient, before assistance was given by the forceps, acting on the assumption that the uterine powers might again return and complete the labour. During the last few years this practice has been completely changed; it is now the rule, when Nature's efforts fail to expel the child within a reasonable time, to give assistance with the forceps at once. If the operation is performed before the nervous energies become exhausted, the uterine pains will act harmoniously with the traction of the forceps, but if exhaustion sets in, this traction seldom succeeds, but often causes incalculable injury to both mother and child. Acting on this principle, I have always had the greatest success in the use of the forceps. I never lost either mother or child, when the case was under my care from the commencement of labour; but when sent for by the midwife, after the child's head had been in the pelvis for many hours, subjected to continued pressure, and the mother in an exhausted state, it was scarcely to be expected that the child's life could be saved by any operation, even when skilfully performed. During my practice I have never met with cases requiring the use of the long forceps or those peculiar cases in which Dr. George Johnston has so successfully operated when the os uteri has been rigid and undilatable. My experience has been confined to cases of tedious labour, arising, for the most part, from inertia of the wound, and I have never applied the forceps under such circumstances until the os uteri was fully dilated.

The plan I have adopted in applying the forceps is very simple, and differs from that laid down by most authors who have written on the subject; it will not succeed where the head is impacted, or where there are deformities of the pelvis, but it may be applied with ease in the different forms of presentation of the head. I have been so successful in applying them in every case that my assistance was required, that I do not hesitate to recommend the plan to others. Dr. Churchill, in his treatise on "Midwifery," mentions a mode of introducing the forceps in cases of midwifery. He says (a) "both blades being introduced posteriorly, we may gradually slip them to either side." Dr. Braithwaite also adopts a plan much similar to that recommended by Dr. Churchill. Its peculiarity consists in (b) "both blades being introduced at once, directly into the hollow of the sacrum, the blades are then to be glided round the head in opposite directions, and locked in the ordinary way;" but the mode I adopt differs essentially from the plans recommended by these practitioners. I will endeavour to explain this method as clearly as I can. Having first emptied the bladder and rectum of their contents, the patient being placed on her left side, with the legs drawn up towards the abdomen, take one blade of the forceps—Churchill's I prefer—warmed and oiled, introduce the blade into the vagina along the floor of the perinæum, at almost right angles with the sacrum, then depress the handle, and gently press the blade upwards between the child's head, and the hollow of the sacrum, until the blade enters the uterus. In the event of uterine pains coming on during the application of the instrument, the operator should, at once, stop his efforts till the pain subsides; the next step is to bring this blade from left to right, describing half a circle over the child's head, until

the blade reaches over the os pubis. I need scarcely say that the greatest gentleness is required in this part of the operation, force should not be used under any circumstances. Keeping, then, this *in situ* anteriorly, you give its handle to an assistant or to the nurse-tender, whilst you proceed to introduce the second or posterior blade. This you do in the same manner as described for the introduction of the first blade, conducting it between the child's head, and the hollow of the sacrum, until the second blade enters the uterus. In introducing this second blade, you must be careful that the instrument is passed *over*, and not under the shank of the anterior blade, otherwise, when you draw the hands together, they will not lock, but if applied accurately, when brought together, they will lock with ease. This plan I have successfully adopted in numbers of cases, without injury to mother or child; it is very probable that other practitioners have adopted a similar mode of applying the forceps. I have not, however, seen any account of it published. It must, however, be understood that neither this, or any other mode of applying the forceps, will prove successful in all cases. Where there is either narrowing of the pelvis, or enlargement of the child's head, the practitioner must use his own judgment, and adopt any plan which will be likely to succeed.

The following case occurred in my private practice about eight years ago, and shows clearly with what facility the forceps can be used according to the method described above. The lady was about 36 years of age; her first confinement. Labour was tedious from the commencement; the os uteri slow in dilating, and when the head descended into the pelvis, after upwards of thirty hours suffering, the pains, though continuing, ceased to be effective. After having waited for upwards of two hours, and having tried ergot, there appeared little chance of my patient getting well without assistance. The lady also became impatient, worn-out with the tediousness of the labour. Under these circumstances, I explained to the husband of the lady, the difficulties of the case, and asked him if he would wish to get the opinion of another medical practitioner before I gave any assistance. His answer was, I have every confidence in you: do what you think is right. I went immediately to work, applied the forceps, after the manner described, used gentle traction with each pain, the uterus responded to my efforts, and a living child was born. I then told the nurse-tender to inform the husband of his wife's safety. This gentleman told me afterwards, it was exactly ten minutes from the time I had his permission to operate, until the child was born. I do not relate this case for the purpose of encouraging others to perform this operation quickly; on the contrary, I think that the greatest deliberation should be used in carrying out its various details. But I think the case worthy of being placed on record, as it shows, not only the facility, but the success with which the operation was performed.

I may casually remark that I had two cases under my care in which the arm presented. I felt no difficulty in turning the child, as soon as the os uteri was fully dilated, without the aid of chloroform, but I would not hesitate to put a patient under its influence, if the contractions of the uterus were continuous, violent, and grasping the body of the child with firm spasmodic action. Under these circumstances, it would be impossible to turn the child safely in the uterus, without the anæsthetic effects of this drug being first produced.

Amongst other reminiscences in midwifery practice, I can bring to my recollection cases of puerperal convulsions and puerperal insanity, which occurred in my private practice, but to enter upon such important subjects, would extend this paper to too great a length.

LONDON does not seem the only city afflicted just now with small-pox; Paris, Vienna, Madras, and Philadelphia are showing high rates of mortality from this disease.

NOTES ON A CASE OF CONSTIPATION  
SIMULATING TYPHOID FEVER.

By G. HARRISON YOUNGE, L.K.Q.C.P.I.,  
L.R.C.S.I., &c.

THE notes of the following case may perhaps interest some of your readers, as I believe it to have been one of constipation giving rise to symptoms exactly resembling those of typhoid fever.

In February, 1880, I was called to see C. E., a young girl, about 17 years of age, who had been feeling unwell for some time. I found her complaining of pain and uneasiness in the right iliac fossa.

On examination she complained of tenderness, and there was gurgling on making slight pressure. There was, however, no evidence of accumulation of fæces, although she stated that her bowels had not been acting as regularly as usual for some time past. She had been suffering from diarrhoea for some days before I saw her, and the stools presented an appearance very like those of typhoid fever; but they could not be regarded as typical. The tongue was covered with a thin white fur along the dorsum, with enlarged papillæ, while the edges were clean and red. There was also nausea and loss of appetite.

She had a slight malar flush, while the eyes were clear and bright, and the pupils somewhat dilated. The thermometer showed a temperature of 103.5°. The pulse was 120.

From the previous history it appeared that she had never been very strong; but she presented by no means an unhealthy appearance, and she had been regularly attending to her work until about ten days previous. About that time she had begun to feel unwell, but she could not say that there was anything in particular with her. Her appetite had gradually failed, she complained of slight headache, and had several shivering fits. The latter, however, were not well-marked. She stated that her bowels had not been quite regular for some time past, but yet she had not been troubled with any marked constipation.

On the third morning of my seeing her she complained of a good deal of pain in the right iliac fossa, and the temperature had gone up to 104°. On this occasion also I discovered two or three small rose-coloured spots on her abdomen, which disappeared on pressure, but quickly returned. These I considered typical typhoid spots.

When I saw her next morning, she complained so much of pain in the right iliac fossa that I ordered her some pills, each containing half a grain of opium—one to be taken whenever the pain was very troublesome.

After taking half-a-dozen of these pills she stated that she suddenly "felt as if something had given way inside her." Shortly afterwards she felt a great desire to go to stool, and having done so, a large chamber-potful of fæces was passed. During the day she had several other motions, and felt considerably better.

When I saw her at my sixth visit I found the temperature greatly lowered; and although she felt very weak, she was much improved in every way.

Two days afterwards the thermometer registered a normal temperature; and on the ninth morning she felt so much better that she insisted on sitting up for a short time. When I saw her in about ten days afterwards she was going about as usual, and stated that she felt better than she had done for some months previous to her illness.

*Remarks.*—From the symptoms I have detailed I was naturally led to believe that the case was one of typhoid fever, and I treated it as such. From its termination, however, it was one of constipation. The sensation "of something giving way" was due to the opium, which she was then taking, overcoming the spasm of the circular muscular fibres of the cæcum, and thus allowing of the onward passage of the fæces. In fact, the case was one of typhilitis caused by fæcal accumulation, and accompanied by an extraordinarily high temperature. Of this,

however, I am fully convinced, viz., that typhoid fever, or at least a disease closely resembling it, may be produced by long continued constipation. And this result may be produced in one of two ways: Either the accumulated fæces cause irritation, enlargement, and subsequent ulceration and destruction of Peyer's patches; or else the retained excreta, becoming decomposed, give rise to noxious gases, which are absorbed and produce poisoning of the system in exactly the same manner as if they were introduced from without. Is it not as likely that this might occur as that puerperal fever might result from a small piece of membrane being retained, and undergoing decomposition? If these statements be true the administration of an enema at the commencement of a case of typhoid fever, which had been preceded by constipation, would be of the greatest service. The subject is, at least, worthy of further attention, and I hope that those who have extensive opportunities of observation may be led to investigate it.

## Clinical Records.

### NORTH-EASTERN HOSPITAL FOR CHILDREN.

*Two Cases of Acute Laryngitis with Broncho-Pneumonia—Recovery.*

Under the care of Dr. C. E. ARMAND SEMPLE.

THE two following cases of acute laryngitis are interesting from their being in the hospital at the same time; presenting much the same symptoms, which were at first extreme; both accompanied with broncho-pneumonic signs, and terminating in complete recovery from laryngeal symptoms.

CASE I.—J. B., set. 7, was admitted into the North-Eastern Hospital on February 18th, 1881.

*History.*—There appeared to be some predisposition to chest affection in the family; two brothers suffer severely from cough, and one of the parents from some bronchitic lung trouble. Two years ago the child had measles, followed by bronchitis; he was laid up with it for some months after, and from that time he has seemed to be always weak, and never thoroughly to have got over the attack; was said to be "weak at the chest." Six weeks before admission he was taken ill with sickness, pains in the head and back, constant cough, and feverishness; the voice was somewhat hoarse, and there was some noise when he drew in his breath. These symptoms lasted for about four weeks, and then abated. He seemed to get much better, and remained so for some days, when, one week before admission, all the symptoms suddenly returned, with great difficulty of breathing and lividity of the face, so that he is now obliged to sit up in bed and fight for his breath.

On admission the child was pale and anæmic, but well nourished; lips pink, no lividity; alæ nasi slightly dilating. He sits up in bed with great difficulty of breathing; respiration regular, accompanied by a good deal of muscular action. Each inspiration was accompanied by a harsh, loud, laryngeal sound; expiration prolonged but not noisy. There was slight sinking in of the episternal notch and supra-clavicular fossæ and of the lower intercostal spaces. He had a very loud, constant, hoarse, ringing cough, almost metallic in character. The inspiratory sound during the act of coughing was a little harsh and laryngeal. The voice was harsh and muffled—almost a whisper. Deglutition easy; no pain. Tongue coated with white fur. Pulse good and regular, 100; temp. 100.4. Pharynx and fauces congested. No membrane to be seen anywhere; chest well formed. On auscultation, respiration harsh and loud all over chest, and accompanied by loudish sounds. At both apices, in front and behind, dry rachi were to be heard, loudest upon the right side; some occasional coarse crepitation towards the apex and base.

He was immediately placed in a special ward, under a steam tent, and the following mixture ordered every four hours:—

B. Pot. chlor., gr. v.;  
Vin. ipec., ℥ iv.;  
Æther sulph., ℥ iij.;  
Aq. calcis, ʒ ss. M.

19th.—Slept well all night. Cough very incessant; not

quite so ringing as on admission. Expecterated during the night a little muco-purulent froth, tinged with blood. Respiration not so noisy. Dyspnoea not urgent. Voice is distinguishable, but very low and whispered. Evening temp. 99.8°; pulse 120; resp. 40.

20th.—Evening temp. 101.4°; pulse 112; resp. 44. Urine of a clear, amber colour, sp. gr. 1022. No albumen or deposits.

21st.—Slept well the last two nights; no distress of breathing, which is quiet, easy, and regular, with very slight laryngeal noise; still a little sinking in of supra-thoracic fossæ. Cough constant, dry, and ringing. Takes food well. Milk and beef-tea. Examination of the throat only revealed a congested state of the pharynx. Evening temperature 101°; pulse 124; resp. 36.

23rd.—Cough better; not so troublesome or constant, but still of a laryngeal character; respiration quiet and regular; some sinking in of chest, especially when the child is excited; a good deal of frothy expectoration. Appetite good. Voice not quite so hoarse, although very muffled and low. Evening temp. 99.6°; pulse 112; resp. 36.

25th.—Greatly improved. No dyspnoea; no sinking in of chest; very little expectoration of frothy mucus. Cough not so loud or continuous. Evening temp. 98.6°; pulse 104; resp. 28. Epiglottitis and folds still very congested. Urine clear, straw colour; acid reaction; sp. gr. 1030; no albumen, but loaded with lithæa.

27th.—Voice more distinct. Cough harsh; and ringing. Sleeps and takes food well. Evening temp. 99°; pulse 112; resp. 28.

*Chest.*—At the right apex behind there was some evidence of consolidation; note on percussion deficient, with tubular breathing. Opposite scapula a few largish rhonchi were to be heard. Breath-sounds over rest of chest were a little shallow; no râles. Diet milk and beef-tea.

March 3rd.—Respiration normal; no noise; cough not so loud; voice a little low, but distinct. Steam tent removed. Pot. chlor. gr. v., and 10 minims of tr. ferri perchlor. ter die.

March 7th.—Very slight occasional dry cough. Pharynx showed a little congestion, about base of fauces. Voice a little feeble. Diet full. Temp. 98.2°; pulse 96; resp. 26.

March 11th.—Able to speak quite clearly; very slight occasional cough.

13th.—Left the hospital to-day; greatly improved in appearance, regaining colour in face.

CASE II.—Rebecca T., æt. 1½, admitted into the North-Eastern Hospital for Children, February 16th, 1881.

*History.*—Ailing and weakly from birth. For twelve months had been subject to cough, off and on, and for three months had eczema over legs and body. Well for two weeks before admission. The last four weeks the cough became very troublesome and constant, with great paroxysms of coughing day and night. She was taken by her mother to a dispensary, where she attended for two weeks, when, at the end of that time, she became much worse. Turned blue in the face from the difficulty of breathing during the attacks of coughing, which came on two or three times a day, and left her very exhausted. For the last week she made a shrill noise in her throat whenever she woke up in the night, but her mother did not think that she had ever made a croupy noise. The night before admission she struggled, and fought for her breath. On admission the child's face was livid, and lips of a crimson blue tint. There was considerable difficulty in breathing, and sinking in of episternal fossæ and intercostal spaces. The difficulty of breathing became very excessive during examination of the throat. The pharynx was very congested, but no membrane was to be seen. Throat full of muco-purulent froth. Each respiration was accompanied by a loud, coarse, laryngeal sound. Was able to say a few words in a hoarse whisper. Cough was loud, hoarse, and ringing. Resp. 26. *Chest.*—Laryngeal sounds loud, with short inspirations, accompanied by sibilant râles. Respiration very prolonged, and whistling at apices behind; few coarse râles. Pulse good and regular, 124. Temp. 99°. Placed in a special ward with Case No. 1, and in a separate steam tent.

17th.—One attack of coughing last night, but slept well. Takes milk freely; is able to swallow without any difficulty.

18th.—Breathing regular; no great dyspnoea, except when the throat was examined. Inspiration, accompanied by a loud laryngeal sound, with considerable sinking in of intercostal and supra-clavicular spaces. Face of a bluish crimson tint; sets up in bed. Cough not constant, hoarse, and not very ringing. Evening temp. 99°; pulse 100; resp. 32.

20th.—On examining throat, pharynx congested—throat full of muco-purulent froth. The examination causes great distress, and lividity of face. Respiration still very harsh, regular; inspiratory sound not so loud; still sinking in of chest, and dry cough. Temp. 99°; resp. 28; pulse 100.

22nd.—Still a good deal of sinking in of chest when the child is disturbed, otherwise the breathing is much improved. Inspiration, accompanied by hoarse tracheal sounds; no lividity of face; slight hoarse cough. Takes milk and beef-tea well. Tongue a little coated in the centre.

25th.—Greatly improved. Respiration not so harsh; a little tracheal inspiratory sound; slight sinking in of chest when she lies quietly in bed. Very irritable bad tempered child; commences to cry whenever she is offended, and so brings on long-drawn inspiration with loud laryngeal sounds. Temp. 88.6°; pulse 96; resp. 28. On examining the chest there were whistling ronchi, and coarse râles at the right side, front and back, and a few at the left back. On the right side, opposite the angle of scapula, was an area of deficient resonance, with tubular breathing. Pharynx and fauces congested and swollen.

28th.—Respiration quiet and regular; voice clear and good; appetite good; slight hoarse cough.

March 1st.—This morning inspiration a little harsh, and slight sinking in of episternal notch. Temp. 99.2°; resp. 28.

March 4th.—Steam-tent left off. No cough; appetite good. Still scattered râles over both sides of chest. Respiration quiet and regular; voice clear. Temp. 98.2°; pulse 80; resp. 26.

13th.—Left the hospital greatly improved; very slight cough; respiration quiet. Some dulness remained opposite angle of left scapula, and scattered râles over chest.

#### Skeleton analysis of ½ a pint (10 fluid ounces).

Total Solids.	Antacids.	Salines.	Purgatives.
17 grs.	11½ grs.	5 grs.	½ grs.

In giving Fresenius' analyses of the EMS waters we

have placed them before the reader just as he states them, but we know that the diads—lime, magnesia, manganese, baryta, and strontia do not exist as bicarbonates, and we have avoided this mode of expression in our analyses, and have also always calculated them as  $M''CO_3$ . In this instance, however, we have adhered to the analyst, and his mode of expression, premising that if calculated as bicarbonates it would bring out these salts higher than we should give them in calculating an analysis of our own. It is self evident that the carbonic gas which holds these bases in solution would also be estimated a second time as free carbonic acid, and inserted in the analyses twice over.

LA BOURBOULE—Source Choussy.

Arsenical, but strongly alkaline, are the Bourboule springs—Puy du Dome, France. There are two principal springs, Choussy and Perrière, but we have only met with the first-named water. This source (Choussy) rises at a high temperature, 108 Faht., from two openings Thénard first announced the fact that this water contained large quantities of arsenic, and states that it exists as arsenious acid, or as neutral arsenite of soda. The water is compared with Ems. The proprietors say, "Ems water and that of La Bourboule-Choussy resemble each other very closely, with the exception of arsenic, which is only found in the waters of La Bourboule-Choussy. It contains—

Bicarbonate of sodium	...	...	100.22
Carbonate of calcium	...	...	11.33
Chloride of sodium	...	...	221.00
Chloride of potassium	...	...	4.12
Chloride of magnesia	...	...	2.54
Arsenious acid	...	...	0.80
Sulphate of potassium	...	...	9.20
Ferric oxide	...	...	0.37
Silica	...	...	1.99
Alumina (trace)	...	...	
Lithium (trace)	...	...	
Ammonia (trace)	...	...	
Total solids			351.47

Free ammonia not determined.

Skeleton analysis of  $\frac{1}{2}$  a pint (10 fluid ounces.)

Total Solids.	Antacids.	Purgatives.	Salines.
22 grs.	.7 grs.	$\frac{1}{2}$ gr.	14 $\frac{1}{2}$ grs.
	Arsenic	...	.05

There is no doubt that the arsenic exists in the water as arsenious acid, or rather we should say as arsenite of sodium, it therefore differs in this respect from the Domique, or arsenious Vals water. This water is another example that most of the arsenical waters are strongly alkaline, and it is much more likely to be the case when the arsenic is in the lower state of oxidation. When it is found associated with the nitrates, or a thoroughly oxidized water we find it generally existing as arsenic acid.

Vide Domique spring. The relative therapeutic merits of arsenious acid ( $As_2O_3$ ) and arsenic acid ( $As_2O_5$ ) is still a moot question. The Choussy seems to be a very pure water.

"SALUS POPULI SUPREMA LEX.

WEDNESDAY, MAY 25, 1881.

TIGHT LACING.

THE claims of fashion have, in all times, pressed more heavily on women than on men, though we come upon frequent examples of males who, influenced by an unnatural craving after effeminate appearance, have submitted their bodies to treatment similar in its consequences to that which has effected so great a degree of evil among women. Earnestly as it has been attempted to inculcate admiration for the healthy proportions of the human figure, and earnestly as physicians have again and again insisted on the incalculable injury done by long-continued tight-lacing, the fact yet remains that the vast majority of women persist in disfiguring themselves, in exposing themselves to ruinous destructive influences, merely because there is expressed in certain quarters a silly liking for the artificial appearances presented by the wasp-like bodies of fashion-hunters. How general the infatuation is; how it has spread from the higher to the

lower classes of society ; and how, in the present day, the utmost reproach a young girl will resent is the charge of possessing a human waist, there is little need to repeat. Even medical men, who recognise and regret the widely extended mischief, are powerless to avert the craze, and save its victims from the frightful danger they are incurring ; and this, not because people are unwilling to be told, or incapable of appreciating the truth, but because it has come to be a necessity of society that there shall be uniformity of disfigurement among its members. Is it, however, futile to hope and to urge that the time has arrived when this need no longer be ? May we not consistently anticipate that a firm and persistent endeavour to awaken a general feeling of disgust against prevailing custom, will be successful ? And given the earnest co-operation of every family adviser who is a member of the medical profession, and thus privileged and able to explain the enormous sacrifices that are made, may we not eventually secure a universal reform in the practice that holds so generally to the detriment, not only of the generation of to-day, but of that also whose mothers are the victims of the present time ?

It is possible to urge that a sufficient importance is not given to the subject by the profession as a body. Every member of it individually will speak indignantly against the ill it occasions ; but we do not find in works intended for guiding future practitioners, that any special stress is laid on the necessity for a vigilant insistence on the suppression of a habit common to female patients as a whole. Medical handbooks vaguely, and in general terms, allude to the complications due to malformations of viscera induced by undue pressure of stays and boots ; and we find, again and again, that the interference with functional efficiency is ascribed to its most frequent cause. But apart from this, and the implied censure such remarks embody on the practice they condemn, we do not meet with direct appeals for the exertion of personal influence towards the suppression of the vice. Surely, however, since the mischief that follows from it is so serious, it is a matter of duty that its consequences should be curtailed as far as is in any way possible. That these consequences are serious, both by reason of their individual extent, and of the numbers affected by them, we have proof frequently offered as the result of observation and experience. So lately as the week just past, the newly-elected coroner for Central Middlesex, Dr. Danford Thomas, held an inquiry concerning the death of a woman in whose body there was found the most unimpeachable evidence of the evils producible by tight lacing. The post-mortem examination revealed the fact, that constant pressure of the stays upon the abdomen over the liver, had produced a deep indentation of this organ, at the spot where they were tightly drawn round by a string. The liver was, moreover, driven down deeply into the abdomen, the medical report describing it as being situated low in the pelvis, and this was possibly no exaggerated statement. As a matter of fact, it is by no means an uncommon occurrence to find the abdominal viscera so frightfully out of their proper position, that anything approaching to a healthy discharge of their functions is an utter impossibility. In the case referred to, the effect produced upon the stomach was remarkable. It was

found contracted in the middle by a firm band, narrowing it to one-eighth of its normal size, so that there were virtually two stomachs. The contraction, moreover, was on a level with the indentation described above ; and Dr. Hill, who made the examination, unhesitatingly asserted that the condition was entirely due to overtight lacing. Dr. Thomas cited other similar cases to the jury, and ventured to express a hope that the publication of them might serve to caution ladies against the practice now adopted. This, of itself, we are confident, will be of little service towards securing a reform in fashion. The attempt must be something more decided and more determined, than the mere description of the dangers incurred. These have been very ably explained and illustrated in a pamphlet on "Dress ; Its Sanitary Aspect," published a few months ago, through Messrs. Churchill, by Mr. Bernard Roth, F.R.C.S., and also in an article in the *Practitioner*, for 1880, by Dr. Douglas Powell. No work of the kind will be generally read and accepted ; the nature of the reform demanded is too serious, and too universal for any but earnest and universal means to avail in bringing it about ; and is therein possible only through a united attempt on the part of the natural teachers of the people, concerning the vital questions of health and hygiene. Even medical men are too much given to accepting what is *because* it is, and Mr. Roth in his little work pointedly expresses the fact by saying, "It was not till I began to devote myself specially to the treatment of spinal and other deformities that my attention was drawn to the subject."

We would commend his remarks on the evil effects of inappropriate dressing to all practitioners, as being likely to elucidate many seemingly inexplicable problems of ill-health and disease. That a vast amount of current illness is principally induced by the outrageous extravagances of fashionable costumes, a little careful observation will clearly prove. Its removal is an imperative duty incumbent on the medical profession.

#### THE NOTIFICATION OF INFECTIOUS DISEASES IN IRELAND.

WE congratulate the profession in Ireland upon the fact that Mr. Gray's Bill, which proposed to compel the physician, under a penalty of £5, to notify all cases of infectious disease which might come to his notice by a written certificate presented by him to the sanitary authority has fallen through. This Bill, as our readers know, has been energetically resisted by the *Medical Press*, in the interest, not only of the profession, but of the public in Ireland, and the opposition to it was taken in hand by the Committee of the Irish Medical Association, who entrusted to Dr. Lyons, M.P., the amendments proposed by them for the purpose of freeing the physician from such an incubus. On Friday night last the Bill came on for Committee, it having got a second reading by surprise, in consequence of Dr. Lyons's absence from the House. On this occasion Dr. Lyons was in his place, and having failed to obtain from Mr. Gray any assent to the proposed amendment, he moved that the House be counted, which, being done, the Bill became a dropped order, and cannot be proceeded

with in the present Session. Thus we hope we have heard the last of a most ill-advised attempt to introduce to Ireland a system entirely unfitted for its people, or its medical system, and the profession in Ireland may thank the Irish Medical Association, and Dr. Lyons, for rescuing them from the imminent danger of having a duty imposed upon them which, while it would serve no good purpose, would put the entire profession in Ireland at loggerheads with the public.

In writing the epitaph of Mr. Gray's Bill, we regret we cannot congratulate that gentleman on the method he adopted to get his Bill through the House. Having, in spite of the remonstrance of the profession, pushed it to a second reading, he made a speech which, we feel it necessary to say, entirely misrepresented the views of the profession, and was intended to mislead the House of Commons. The medical promoters of the Bill had sought to cushion opposition by promising that it should be referred to a Select Committee, but they seem to have taken no step towards keeping this promise, for no such proposal was made by Mr. Gray when the Bill came up for debate, and, as we have said, the second reading was obtained by gross misrepresentation. Then the Irish Medical Association formulated its amendments, and sent them to Mr. Gray with the categorical question whether he would or would not accept them. To this inquiry no definite reply could be obtained, though a fencing answer was returned. Finally, Mr. Gray writes, on the 16th of May, a letter stating that he was about to take the Committee on the Bill in a few days, and he addresses this letter in such a way that it did not reach the hands of the Association until the day when the Bill was to be discussed. This is not fair fighting, and, however creditable it may be to Dr. Gray's diplomacy, it says little for his candour, and reflects little honour on those medical men who supported him in his mischievous legislative attempt.

#### NURSING ARRANGEMENTS IN WORKHOUSES.

OUR workhouse hospitals are gradually assuming the position they are entitled to; the profession and the public are beginning to appreciate the importance of these institutions. Sickness is one of the greatest factors in the production of pauperism, hence to satisfactory grapple with this cause is wise economy. This great truth has been arrived at slowly, by a true process of evolution. Guardians of the poor are rendering valuable aid towards the reduction of the rates by placing workhouse hospitals on the same footing as voluntary hospitals, and by providing for the sick poor all the medical necessities, comforts, and appliances, which are found to be of service in all well organised hospitals. If John Journeyman should have pneumonia, if badly treated or neglected, he may become a pauper for life; or if James Dustman contract acute rheumatism, and be not attentively nursed and dieted, he may also become a pensioner on the rates for life. But if both these sufferers be at once sent to the State hospitals—the union infirmaries—under efficient medical treatment, their illnesses will be of short duration, and a slight drain on the local rates will only take place. The guardians are practical men. A simple sum of addition and calculation will convince them that

their present policy is supported not only by humanity, but by every motive of self-interest. True economy will be found to be on the side of efficient medical treatment.

The disease of a month should not become the illness of a year. This is a truism. One of the most important requirements of a good hospital is a good nursing staff. We are now in a position to expect that, as the guardians are alive to the importance of curative treatment, they will appreciate this principle, and that they will be prepared to do away, to a great extent, with all pauper nurses, substituting for them trained aids. The pauper labour now expended in the ward can be turned to better account in the laundry. Loss there will not be if some such plan as the following be adopted. In all modern workhouses there are at least two paid nurses, who have under them a certain number of wardmen or women selected from the inmates, the number depending on the number of sick. Nursing is an art. It requires training and qualities which cannot be acquired by the class now selected for this important office. The average pauper has not the heart, let alone the head, to make a good nurse, and to apply the term to them is a misnomer. Good nurses are scarce. Our workhouse hospitals might be turned to good account in this respect, if the guardians would admit probationers, and allow their medical officers to train and educate them. Thus the pauper help could be dispensed with; fewer nurses would be required; good service would be rendered to the patients; by the substitution of intelligent for unskilful aid, and by supplying the public with nurses, a great existing want would be met.

We do not apprehend there will be any difficulty in getting candidates for such appointments, as at the present time nursing is looked upon as a suitable office for women of all classes, and much more attention has been paid to securing good nurses. Our voluntary hospitals but imperfectly supply training fields, as only a limited number of probationers can be received. The workhouse hospitals—more universally spread over the country, and more numerous—seem admirably adapted for the work. We trust some medical officer will introduce the subject to the notice of his board of guardians.

#### DUNCAN v. OMAGH GUARDIANS.

AN important judgment, which we record in another part of our issue, was given last Wednesday in the First Court of Queen's Bench, respecting the claim of Dr. Duncan for payment for each person re-vaccinated by him in his dispensary district since the passing of the Act of 1879.

It was contended by the Guardians that unless the medical officer could certify that each case of re-vaccination was successful no fee should be allowed; whereas the recent Vaccination Act for Ireland, passed in the year 1879, states at the 6th section "for every person successfully vaccinated or every person re-vaccinated by the medical officer within the dispensary district he shall be entitled to a fee of two shillings."

Respecting primary or infantile vaccination, it is only just and reasonable that the case should be certified to be successful, but in cases of re-vaccination—taking for

granted that the operation is carefully performed—it very frequently occurs that no vesicle, either true or modified, results; and, as a general rule, it may be with safety laid down that the systems of such persons are already protected by the infantile vaccination. It may be well to observe that in some individuals possessing good primary vaccine marks, and who on being re-vaccinated form well-selected vaccine vesicles, some do not show the least result; yet if, in the exceptional cases alluded to, the operation be repeated, well defined vesicles are developed—a practical hint to the medical profession which we consider not out of place.

We hold that Mr. Justice O'Brien's judgment is the common sense reading of the section, and we are surprised the Board of Guardians ever disputed these fees, indeed, it was to remove any doubt that from time to time had arisen respecting payment for cases of re-vaccination that the 6th section of the amended Act was drawn up in its present form by the executive of the Irish Medical Association. We are aware that the Local Government Board for Ireland some years ago issued a circular to the Boards of Guardians upon this same question of re-vaccination fees, and at the time expressed an opinion that where no result followed upon re-vaccination the individual should be considered as protected by the primary vaccination, and therefore the re-vaccination might be looked upon as successful, and consequently the medical officer who had performed the operation was entitled to the usual fee.

We congratulate Dr. Duncan upon the successful issue of the question he has raised, and will only remark that the principle involved was of great importance to the dispensary medical officers of Ireland. The Irish Medical Association was consulted in this matter, and gave Dr. Duncan its hearty co-operation.

#### OUR COMING GENERATION.

In reviewing recently the latest issue of the Register of Medical Students just published by the General Medical Council, we published some figures deduced from that Register as being interesting and instructive to medical educationalists at the present juncture. We stated, as an approximation to the fact, that England educates a little less than half (48.6 per cent.) of the entire number of students; Scotland a little more than a quarter (27.6 per cent.); and Ireland a little less than a quarter (23.8 per cent.); but we added that these figures must be taken *cum grano salis*, inasmuch as registration of students which is universal in England has been greatly neglected, and even intentionally evaded in Ireland. We also noted the difference existing between the systems existing in the three divisions of the kingdom in respect of privilege to general practitioners.

A little more than half (503) the English students commenced their education in the provinces, of whom over one-third (188) began as pupils to medical practitioners. In Scotland, on the contrary, but one student out of the entire number (589) commencing study in this way; and in Ireland only 8 out of a total class of 534. It is a serious question how far this latter class of students will receive any useful instruction during their first year of

study? for it may reasonably be suspected that the certificate of a general practitioner is not always to be depended on, and as the *soi disant* pupil is not examined at the end of his year, there is no other guarantee save this certificate that he has not been simply idling for his first year. We imagine that the four years of study of these students sometimes means three years, and the payment of a fee to the general practitioner, and that a majority of the 188 students who commenced study by this sort of pupilage receive in reality only three years' education.

The number of Irish first year students appearing in the Register for the year was 534, which we pointed out, falls far short of the real number, because student registration in Ireland has been heretofore tabooed by certain schools, neglected by the student, and that neglect tolerated by the Branch Medical Council. These 534 students are divided, as to their place of study, as follows:—

<i>Dublin Schools.</i>				
Ledwich School	...	...	...	91
College of Surgeons	...	...	...	59
School of Physic, Trinity College	...	...	...	55
Carmichael School	...	...	...	45
Catholic University School	...	...	...	32
Stevens's Hospital School (now extinct)	...	...	...	8
Various Hospitals	...	...	...	2
<i>Provincial Schools.</i>				
Queen's College, Belfast	...	...	...	93
" " Cork	...	...	...	83
" " Galway	...	...	...	59
Antrim Infirmary	...	...	...	1

We have reason to hope that in future the Irish section of the Register will be more reliable than it has hitherto been, because the new scheme of education and examination recently adopted by the Council of the Irish College of Surgeons, makes it compulsory on candidates for the license of that College to register at the commencement of study.

Under that scheme many students, we contemplate, will commence study as the pupils of general practitioners throughout the provinces, but there will be an important difference between such pupilage in Ireland and in England, viz., that in Ireland the reality of that year of study will be tested at its termination by an examination in subjects which may readily be made up without school teaching, while in England no such examination is held, and there is, therefore, no guarantee of the *bona fides* of that year of study, except the uncorroborated certificate of the general practitioner who is supposed to have instructed the pupil for his first twelve months—in our opinion a very inadequate assurance.

THE annual rates of mortality last week in the principal large towns of the United Kingdom per 1,000 of their populations were:—Plymouth 14, Bristol 15, Brighton 15, Norwich 16, Portsmouth 17, Birmingham 17, Leicester 18, Salford 18, Bradford 19, London 20, Sunderland 20, Sheffield 20, Liverpool 21, Edinburgh 21, Glasgow 22, Nottingham 22, Hull 22, Leeds 22, Manchester 22, Newcastle-on-Tyne 23, Oldham 23, Wolverhampton 26, and Dublin 29.

## Notes on Current Topics.

### Small-Pox and other Infectious Diseases.

THE adjourned discussion on Dr. B. W. Richardson's address entitled "Some Suggestions for the Management of Cases of Small-pox and other Infectious Diseases in the Metropolis and Large Towns," was continued on Wednesday last, at the Sanitary Institute of Great Britain, when, after several speakers had contributed speeches to the debate, Dr. Richardson replied on the whole discussion. He urged that complete registration of the communicable diseases had been generally approved in principle, and that it was admitted to be desirable for the sanitary committee, or local authority of each parish, to map out all special centres of infection in its district, keeping a record also of the accommodation required from time to time. To the objection that it is impractical to demand each parish to bear the burden attaching to it on account of its own infectious sick, he replied that it had been found practical in some, and was therefore so in all. He defended the principle of isolation, on the ground of the psychological evils following aggregation of numbers in a ward, and the deficient cubic space enjoyed by each under such conditions. The facts brought to prove that large hospitals for small-pox patients are injurious to the surrounding neighbourhood, Dr. Richardson thought, had been conclusively shown by a majority of speakers. In advocating his plan for the isolation of poor patients, he repeated his proposals for effective hospital accommodation, and said that his plan already existed in practice in private houses, where the small-pox sufferer is sent to the top room of the house, is isolated there, and treated, notwithstanding the existing faulty arrangements, with success. London at this moment is, in fact, a badly-managed upper-floor hospital to a considerable extent. Carry that plan out on a better scale for the poor who suffer by making a sufficient number of small efficient upper floors. There are thirty-nine vestries concerned; for arguments sake divide equally. Let each vestry, on its boundaries, set up four hospitals of light construction on the upper floors of existing, or of new buildings. Let each hospital take in twelve patients. There would then be accommodation for 1,872; and if, by a mutual accommodation between parishes one would receive for another in emergency, the whole question of dealing with the out-of-home infectious cases in London would be solved. Such small hospitals would not even be noticed after a time, and their management would be so easy that they could not be sources of danger if any efficiency deserving the name of efficiency were bestowed upon them. To the last objection that if his proposals were legislatively carried out the sick would not receive the highest medical care, he replied, only carry them out, and the medical care is sure enough. It would be as easy to secure the best consulting skill that medicine can afford for the small, as for the large, hospitals. Dr. Richardson illustrated his observations by showing a very excellent model of a small iron hospital, arranged for destroying organic emanations by fire, constructed by Mr. Thomas Veryard, of 3 St. Andrew's, Wandsworth Road.

### Railway Servants and their Work.

THE sympathy felt by the general public with the grievances of railway employes was forcibly shown at a largely-attended meeting held in Exeter Hall last week. For some considerable time, occasional expressions of opinion adverse to the policy of railway directors in enforcing lengthened spells of duty from those entrusted with the onerous responsibility of the enormous traffic of the country, have been heard, and at those times when it has seemed all but inevitable that a deadlock in the service would ensue, in consequence of inattention to the reasonable demands of the men, the travelling public have not been slow to evidence their disapprobation of the excessive tasks imposed on the servants of the great companies. The safety of the vast majority of the population is undoubtedly dependent at times on the physical well-being of those who have charge of the trains containing passengers; and it is equally certain that in a very large number of instances such officers are improperly and dangerously overworked. Any agitation which will compel attention to these questions is deserving of universal support, so long as it is conducted by legitimate means of discussion and suggestion. So far the railway employes have observed a commendable calmness in their method of conducting the business of obtaining redress; and so long as they continue to pursue the aim they have in view in the same spirit, there is little doubt that public opinion will be with them. There is little enough reason for refusing their just demands; there is every reason why they should be conceded.

### The Coming of the Professional Gathering in Dublin.

ARRANGEMENTS are being matured for the holding of the annual meetings which are held in Dublin in the first week in June. The meeting of the Fellows of the Royal College of Surgeons to receive the Annual Report of the Council will be held, as we have already stated, on Saturday, the 4th of June, instead of the previous Monday. This day has been fixed for the future in conformity with the recommendation adopted by the College at large at its general meeting of last year, and the object of the change is to meet the convenience of the Fellows who reside at a distance. Heretofore, if those Fellows wished to take part in the annual general meeting of the College they had to come to Dublin on the last Monday in May, and if they wished to exercise their elective rights, had to return to town a week afterwards, on the first Monday in June, the result of which arrangement was that most of the provincial Fellows could not attend on both occasions, nor could they discuss the Report if they meant to vote at the election of Council. To make the annual general meeting more attractive to the Fellows, and afford those who are connected with the College an opportunity of entertaining their friends within its walls, the annual dinner of the College "Club" has been fixed for Saturday evening the 4th, when it is expected that many of the extra-metropolitan Fellows will be present as guests. On Monday the 6th the annual election will take place, at which, in addition to the outgoing Councillors who seek re-election, many new candidates will offer themselves to

the constituency. In addition to Mr. Baker and Mr. E. H. Bennett, whose candidature we have already announced, Dr. Roe, Professor of Midwifery in the College, Dr. Meldon, of Jervis Street Hospital, and Dr. Kendal Franks, of the Adelaide Hospital, have placed their names on the ballot list. Mr. Barton will be unopposed in his candidature for the Vice-Presidency; Dr. Chaplin, of the Kildare Infirmary, who now occupies the vice-chair, will, of course, succeed to the Presidency *nem dis*; and as we understand that Dr. McClintock, the outgoing President, will not seek re-election, there will be a vacancy in the ranks of outgoing Councillors who seek re-election. A change in the method of voting which, in our opinion was much needed, and which we believe will enhance both the dignity and freedom of election, has been made by the Council with the view of preventing importunate canvassing for votes within the walls of the College. Heretofore, the voter has found it difficult to mark his ballot paper without being overlooked, as he had to do so at a large table in the centre of the board room, where he was liable to be importuned for his vote in a manner which was very unpleasant and scarcely decent. In accordance with a formal resolution of Council, to which there was but one dissentient, a Committee was appointed to consider a remedy for this system. They recommended that the ballot paper should be sent to each Fellow before the day of election, and that voting compartments of a size to hold one person only, and similar to those used in Parliamentary elections, should be erected in the room in which the blank ballot lists should be placed for the use of voters. This arrangement has been adopted, and it will, we hope, be found effective in preventing undue canvassing and a reasonable protection to the voter in the exercise of his suffrage.

#### Death of Dr. Sandwith.

THE medical profession, no less than the general reading public, will have read with deep concern of the death of Dr. Humphry Sandwith, which occurred in Paris on the 16th inst. Dr. Sandwith was well known as the author of a highly-successful volume descriptive of the siege of Kars; but his claim to the gratitude of mankind is founded on higher grounds than any merely literary excellence could bestow. On the cure of the wounded, and on hospital organisation, Dr. Sandwith was an authority whose great experience conferred vast benefits on the unfortunate victims of war; and as a competent advocate of practical hygiene there are few who can be said to have served more devotedly, or with greater success. For his manifold services as chief medical officer with General Williams during the siege of Kars he was rewarded with the distinction of a C.B., and his worth was further recognised by the University of Oxford with the honorary degree of D.C.L. Dr. Sandwith was M.R.C.S. Eng. and L.S.A. Lond., and had reached the age of fifty-nine. He was at one time anxious to enter Parliament, and contested Marylebone in the Liberal interest in 1868, but unsuccessfully. He always evinced the highest interest in the Eastern question, and both wrote and spoke much in connection with it. The profession loses in him a valuable and devoted adherent to the cause of hygienic reform, and his friends will long mourn one whose noble qualities endeared him to an extent his loss alone can testify.

#### The Health of Ireland for the Past Quarter.

THE deaths registered in the Dublin district during the quarter ending Saturday, April 2, amounted to 317, affording an annual ratio of 37·6 in every 1,000 of the population. The average in the fourth quarter of last ten years was 2,798, or 33·6 per 1,000 persons. As was pointed out in previous reports, the burial returns under the Public Health Act came into force in 1879, raising the number of deaths registered to about 10 per cent. over the number registered in previous years. In addition to these returns further improvements in registration have been produced by the action of the "Births and Deaths Registration Act (Ireland), 1880," which came into force on the 1st January of this year. The death-rate north of the Liffey registered last quarter was 41·6; south of the river, 38·9. In the suburban districts of Contarf and Howth, Coolock and Drumcondra, Finglas and Glasnevin, Palmerstown, Rathmines, Donnybrook, Blackrock, and Kingstown, the death-rate was 28·2. The annual mortality registered in London during the quarter was 23·3; in Glasgow, 27·2; and in Edinburgh, 22·2 per 1,000 of the population.

The deaths from zymotics were 405, being 110 under the number for the preceding quarter, and 121, or 23 per cent. below the average for the first quarter of the last ten years. Small-pox caused 10 deaths, being 4 under the number of the preceding quarter, and 51 under the number for the first quarter of 1880. Only 11 deaths from measles were registered, being 18 under the number for the preceding quarter, and not exceeding one fourth of the average for the first quarter of the last ten years. Deaths from scarlatina, which numbered 121 in the December quarter of 1880, fell to 56 last quarter, being 24 under average. Diphtheria caused 15 deaths, against 7 in the preceding quarter. Fifty-one deaths were ascribed to whooping-cough, showing a decline of 20, 10 under the average for the first quarter of the last ten years. Fever caused 145 deaths (85 typhus, 42 typhoid, or enteric, and 18 simple continued), being 31 in excess of the number for the preceding quarter, and 53 over the average for the first quarter of the last ten years: the increase may be said to have been confined to deaths from typhus. 470 new cases of typhus were admitted during the past quarter, and 94 remained under treatment on 2nd April, being 69 under the number in hospital at the close of the previous quarter. Among the remaining deaths from zymotic diseases are 26 from diarrhoea, 10 from erysipelas, and 16 from croup.

Diseases of the respiratory organs proved fatal in 909 instances, being 371 in excess of the number for the previous quarter, and 198 over the average for the first quarter of the last ten years; the deaths in this group comprise 720 from bronchitis, 113 from pneumonia, or inflammation of the lungs, 6 from pleurisy, 3 from laryngitis, 3 from asthma, and 64 returned as from lung disease, unspecified. Forty-eight deaths were ascribed to apoplexy, 71 to paralysis, 25 to cephalitis, 6 to insanity, 11 to epilepsy, 37 to brain disease, unspecified; 186 to diseases of the heart and circulatory organs, 9 to hepatitis, or inflammation of the liver, 44 to liver disease, unspecified; 12 to nephria, or Bright's disease; 4 to nephritis, or inflammation of the kidneys, 1 to ischuria, 4 to diabetes, 1 to stone in the bladder, 3 to cystitis, and 16 to kidney disease, unspecified.

### Army Medical Departmental Dinner.

It is announced that the officers of the Army Medical Department will have their first annual dinner on Saturday, June 4th, at the Inns of Court Hotel, at 7.30 p.m. The intended dinner is doubtless to be the first of at least the third series of such entertainments, and will, it is hoped, prove to be a success. But in days now long gone by, gatherings of the same kind took place annually at the old "Thatched House" in St. James's Street; a well-known, but even then *mysterious*, member of the department, namely, Inspector-General James Barry, being tolerably constant in his appearance on such festive occasions. Soon after the death of Sir James McGirgor, these annual celebrations ceased. Subsequently a second series was begun, but came speedily to an end. Now the third series is contemplated. May its continuance be equal to *that of the first*.

### Exchanges between Medical Officers.

IN future, exchanges between officers of the Army Medical Department will, it is said, be permitted, but with certain limitations. In India they will be allowed so long as the officers exchanging are both in the same Presidency; but this is not at all likely to be the case, as in the generality of instances a chief cause of seeking an exchange is that one officer may thus leave a Presidency he dislikes to proceed to one that he prefers. Medical officers in India exchanging with others in England will, it is expected, forfeit their pay during the interval between their own departure from, and arrival of their successors in, that country. If this rule is also to hold good with regard to "combatant" officers, let medical officers by all means be subject to it also. But if it is to apply to them only, then the arrangement is not only illiberal, but invidious.

### The Minutes of the General Medical Council.

THE volume of the Minutes for the portion of the year which has passed, has been issued with praiseworthy alertness and accuracy by Mr. Miller, the Registrar. It contains not only the official record of the doings of the Council within that period, but a full statement of the yearly accounts, which is instructive reading for all critics of the Council. The revised standing orders of the Council are also bound up in the book, which is now on sale either of the Messrs. Spottiswoode, or at the Council head or branch offices.

### Affections of the Skin in Colliers.

DR. PAUL FABRE, of Commentry, recently brought before the Congress of Learned Societies the result of his observations on the affections of the skin most frequent among colliers.

Of these affections some appear due to the influence of humidity, and these may be cited in order of decreasing frequency, erythema nodosum, papules, erythema, purpura simplex and purpura hæmorrhagica. Others are due to the influence of the heat reigning in some pits, and Dr. Fabre cites as frequently present, a kind of military vesicular eruption of sudamina, which seems to resemble what naval surgeons have described under the

name of eczema of hot countries, "*bourbouilla*." These symptoms are generally accompanied by considerable itching and sometimes simulate prurigo. The workmen scratch themselves violently or get their fellow workmen to scratch them, so that the epidermis is often torn. And if under these circumstances, as Dr. Fabre has sometimes observed, to the heat is added the permanent action of water charged with sulphuric acid or other irritant principles, the most severe smarting replaces the itching.

Lastly, in some subjects, the long continued work in a hot atmosphere is followed by an eruption of furuncles and sometimes even of lichen. The coal dust does not exercise any maleficent action on the skin. The coal indeed has no other inconvenience when it cuts and penetrates the skin, than that of leaving an indelible blue cicatrix, which may, from a medico-legal point of view, on account of its persistence, be considered as one of the best signs of identity.

### Legacies to Medical Charities.

THE following institutions have become possessed of legacies during the past few days by the formal proving of the respective wills. From Mr. Samuel Courtauld, of Gosfield Hall, Halstead, Essex, £2,000 each to the London Hospital and the Essex and Colchester Hospital, and £1,000 each to the Charing Cross Hospital, the Royal Free Hospital, the East London Hospital for Children, Shadwell, and the Royal Hospital for Consumption and Diseases of the Chest, City-road. From Mr. Charles Stephen Barron, of 16 Orsett Terrace, Hyde Park, £4,000 to St. Mary's Hospital, Paddington; £2,000 each to the Surrey County Hospital and the Hospital for Consumption and Diseases of the Chest, Brompton; £1,000 each to the Royal Hospital for Incurables; the Small-pox Hospital, Highgate; the Great Northern Hospital, Caledonian-road; the Cottage Hospital, Ventnor; the Middlesex Hospital; Charing Cross Hospital; the Metropolitan Convalescent Institution, Walton-on-Thames; and the East London Hospital for Children, Shadwell. From Mr. Thomas Biggart, late of Baidlandhill, £200 to the Western Infirmary, Glasgow. From Colonel Gascoyne £100 each to the Royal Hospital for Incurables and the National Hospital for the Paralyzed and Epileptic.

### Income of St. Bartholomew' Hospital.

ACCORDING to a statement in the *Charity Record*, the accounts of St. Bartholomew's Hospital for the year 1886 show that the cash "available for hospital purposes" came to £77,100 odd; and that there was a balance of over £5,686 in favour of the institution. Diet for patients and nursing staff cost £13,607; drugs, chemicals, wines, spirits, surgical instruments, and dispensary sundries, £7,166; salaries of medical officers, civil officers, and servants, £6,684; pay of sisters, night superintendents, nurses, staff of nurses' home, and ward scrubbers, £5,716; washing for patients and nursing staff, £2,229; wages of dispensers, laboratory men, clerk of the works, carpenters, &c., £3,963; gas, £1,139; coal and firewood, &c., £1,196. These, and the expense of the Convalescent Home, Highgate, viz., £1,380, were the principle items of expenditure for direct hospital purposes. The "extra expenditure" included the large sum of £18,536 spent—and well spent—on new build

ings, museum, library, lecture-theatres, dissecting-rooms, &c., for the Medical School.

#### Tattoo Marks as Anatomical Guides.

A PARIS letter gives this item:— Henceforth, be it understood, the dermatographic artists will be looked upon as valuable auxiliaries to surgery. "Why is it," asks Dr. le Comte, who is physician to a regiment of dragoons, "Why is it that such quantities of soldiers die upon the battle field?" And then he replies, confidently: "Simply because of the difficulty which arises in regard to arresting hæmorrhages." The compression of an artery being the best mode of stopping profuse bleeding, Dr. le Comte proposes to teach each soldier first where these vessels are situated, so that he may assist himself while waiting for a surgeon. Therefore, he tattoos an image of some kind upon every portion of the soldier's body where there is an artery.

#### An Explosive Mixture.

AN explosion of an extraordinary nature recently occurred at the shop of a druggist in Wigan. A woman went to the shop and asked the assistant for a mixture of spirits of nitre and vitriol. The assistant declined at first to supply the mixture, stating that the spirits would burst the bottle and that she would get badly burnt. The applicant said she had procured the mixture before for cleaning buttons and clothing, and pressed the assistant to prepare the mixture. The assistant at length made up a mixture of spirits of nitre and vitriol, but no sooner had he corked the bottle than the contents exploded, and burnt him severely about the eyes. The applicant and another person who was waiting to be served, were seriously burnt on the face.

#### Elongation of Nerves in Tetanus.

AT a recent meeting of the Soc. de Biologie, of Paris. (Feb. 26th), M. Poncet presented an observation of a case of tetanus, terminating in death, notwithstanding the administration of twelve grams of chloral per diem. No neuritis of the collateral nerves of the injured thumb or of the median nerve of that arm could be found by M. Poncet or M. Mathias Duval, and they were unable to find any trace of the bulbar degeneration noted by M. Amidon in such cases. Elongation of the nerve, successful in a few cases, is generally without avail, and in a case of Clark's, which terminated happily, the tetanic symptoms persisted after the operation. In two cases of Eben Watson's, in a case of Hutchinson's and another reported by Morris, the elongation was unsuccessful, and this last author considers it dangerous, as augmenting the frequency and violence of the spasms. The recent experiments of Laborde have demonstrated that elongation arrests the sensitive, but not the motor, current in the elongated nerve.

#### Legacies to Dublin Medical Charities.

SURGEON-MAJOR NEWLAND, of Carrickmines House, co. Dublin, brother of Drs. Newland of Dublin and of Kingstown, has bequeathed £1,000 to Mercer's Hospital, £500 to the Hospital for Incurables, and £250 to the Medical Benevolent Fund Society of Ireland.

#### The Treatment of Scabies.

As the result of experiments by M. Frissart at Saint-Louis Hospital, Paris (*La Presse Medicale Belge*) it appears that carbolic acid may be employed with advantage in the treatment of scabies. Two patients were cured of the affection by friction twice a day with the following mixture: Crystallised carbolic acid, 3 grammes; almond oil, 300 grammes. Dr. Frissart was led to make these experiments by noticing the disappearance of scabies in several patient, affected with it, who had been put under Lister's treatment for some surgical affections.

A CHEMIST at Bridgewater has been fined £10 and costs under the Sale of Food and Drugs Act, for dispensing a quinine mixture ordered by the medical officer of the Union, with only about one-third the due proportion of quinine.

As a result of public subscription, Dr. Evan Pierce, the respected coroner for Denbighshire, is to have a full-length portrait painted for the County Hall, and Mr. Charles Mercier, of London, has been commissioned to execute the same.

THE Treasurer of St. Bartholomew's Hospital, Sir Sidney Waterlow, and the medical and surgical staff, will give a *conversazione* on Friday, the 27th instant, at which the Prince of Wales, the President of the Hospital, will attend, accompanied by the Princess of Wales.

WE learn with much satisfaction that Drs. William Thornley Stoker and Purcell, of Dublin, whose serious illness we reported, are making favourable progress toward recovery. Dr. Purcell's illness which was, at first, apprehended to be typhus has since declared itself as pneumonia, possibly of typhoid origin.

GENERAL PHAYRE in a communication to the adjutant-general in India, brings to the notice of the commander in-chief the good services performed by the medical staff of the Candahar Field Force. The officers whom he specially names are Deputy Surgeon-General Bruce, of the Indian, Surgeons-major Cryan, Jargoe, and Keith, of the Army, Medical Departments.

WE greatly regret to see announced the death at Allahabad of Surgeon-Major Lundy, A.M.D. Dr. Lundy was an officer of long and distinguished service. He served all through the Crimean campaign, including the battles of the Alma, Balaclava, and fall of Sebastopol. He served with the 64th regiment in Persia in 1857; he was subsequently with Havelock's column at the Alumbagh, Cawnpore, &c. He was several times mentioned in General Orders, and had four decorations for his services.

THE presidents of sections at the York meeting of the British Association for the Advancement of Science will be:—For Section A, Sir William Thompson; for B, Professor A. W. Williamson; for C, Professor Ramsay; for D, Professor Owen, who will preside over the department of Zoology and Botany, while over Anthropology Professor W. H. Flower will preside, and in the department of

Anatomy and Physiology Professor Burdon Sanderson ; for E, Sir J. D. Hooker ; for F, Mr. M. E. Grant Duff, M.P. ; and for G, Sir W. G. Armstrong.

In the principal large foreign cities, the mortality, according to the most recent weekly return, was in—Calcutta 36, Bombay 36, Madras 46 ; Paris 29 ; Geneva, 22 ; Brussels 25 ; Amsterdam 23, Rotterdam 21 ; The Hague 25 ; Copenhagen 31, Stockholm 28, Christiana 18 ; St. Petersburg 69 ; Berlin 26, Hamburg 26, Dresden 24, Breslau 29, Munich 31 ; Vienna 35 ; Buda-Pesth 37 ; Rome 25 ; Venice 21 ; Alexandria 34 ; New York 34, Brooklyn, 22, Philadelphia, 25, Baltimore, 20 per 1,000 of the population.

FROM diseases of the zymotic class last week in the large towns measles showed the largest proportional fatality in Bristol and Sheffield ; and scarlet fever in Salford. The 31 deaths from diphtheria included 16 in London, 4 in Portsmouth, and 4 in Glasgow. The highest death-rates from fever (principally enteric) were recorded in Oldham, Liverpool, Glasgow, and Dublin. Small-pox caused 76 more deaths in London and its outer ring of suburban districts, and one in Liverpool, while no fatal case of this disease was registered in any of the other large towns.

## Scotland.

(FROM OUR NORTHERN CORRESPONDENT.)

COMBE LECTURES.—The third lecture of this course was delivered on the 17th inst., by Dr. Andrew Wilson in the hall of the Church of Scotland Training College, Edinburgh. There was again a large attendance. The lecturer gave on this occasion an exposition, illustrated with examples, of the bones forming the human skeleton, and their relation to one another in building up the framework of the body. In speaking of the skull, whose twenty-two distinct bones were described in detail, Dr. Wilson pointed out how, in the higher types, the facial angle indicated a larger cubic capacity for brain, while in the lower the jaws came forward in a manner approaching more nearly to the form seen in apes, or even in lower animals. The skull of the young orang, he said, was remarkably like that of the human infant ; but as it progressed to maturity there came that shooting forward of the facial bones which completed the development of the adult orang, but left its race far behind the human type in respect of brain capacity. So that, whatever causes had brought man up to his present standpoint, among those causes must be regarded and included those which had tended to the forward prolongation of brain lobes and the shortening and compression of the facial bones. Another characteristic of the human skull was that perfect balancing of it upon the neck which enabled man to dispense with such a strong ligament as was found attached to the cervical vertebrae of the horse for the purpose of tying the head to the spine. A ligament of this kind did exist in man, but in a much less developed form. In dealing with the extremities, attention was called to the perfection of the human hand as an instrument of prehension.

LONGEVITY IN SKYE.—From the list of registered poor of the parish of Kilmuir, Isle of Skye, for the past year, we observe that there died recently two persons, one aged 109, and the other 103 years. The former was widow Nicolson, Bailgown, whose total cost to the parish in the year seems to have been 18s. 8d. Of 74 paupers, about 20 are of 70 years and upwards, and nearly as many are aged between 80 and 90 years.

THE GLASGOW DEATH-RATE.—For the week ending with Saturday, the 14th inst, there was an increase of 2 per 1,000 in the death-rate over that of the preceding week, the rate being 26 per 1,000 per annum of the population. The death-rate for the corresponding week in the years 1880, 1879, and 1878, was 30, 23, and 24 respectively.

HEALTH OF EDINBURGH.—The deaths in Edinburgh for the week ending with Saturday, the 14th inst., numbered 93, and the death-rate was 22 per 1,000. Only one death from fever was reported ; there were eight from scarlatina, two of which occurred in the New Town.

NEW HOSPITAL FOR AYR.—A special meeting of the subscribers to the proposed new hospital for Ayr was held on Friday last for the purpose of considering a report regarding the plans and specifications for the buildings, in accordance with the recommendations of Professors Macleod and Gairdner. The lowest tender, including painting, &c., amounted to £7,307, and among the various tenders submitted there were substantial and well-known tradesmen who were willing to accept the contracts at a sum not exceeding £8,000. Mr. Oswald, of Auchincruive, moved that the plans of Mr. Murdoch, architect, be adopted, which was seconded by Colonel Hay Boyd, of Townend. Dr. Dykes moved as an amendment that before the building be begun the specifications be put into the hands of an independent and competent architect to see whether these specifications will give a sound and reliable building, and one suitable for hospital purposes, which was seconded by Mr. John Robertson. On the amendment being put it was lost by a majority of 27 votes.

## Analytical Reports,

AND

REMARKS ON RECENT INTRODUCTIONS IN  
FOOD, DIETETICS, MEDICINES, &c.

### KOPF'S FOOD FOR CHILDREN AND INVALIDS.

By CHAS. R. C. TICHBORNE, LL.D., F.C.S., M.R.I.A.  
Lecturer on Chemistry, Carmichael School of Medicine, &c.

I HAVE carefully examined this food, both chemically and microscopically, and find that it is made from different farinas, and other nutritious ingredients, in such a manner as to give a due proportion of flesh formers (albuminates) and heat producers (carbo-hydrates).

Its chemical analysis gives—

Moisture... ..	1.55
Alkaline salts (containing phosphates 0.17 P <sub>2</sub> O <sub>5</sub> ) ... ..	0.68
Silica, or insoluble in acids ... ..	0.39
Albuminates ... ..	9.10
Carbo-hydrates (including sugar and farinaceous matter) ... ..	82.00
Cellulose and insoluble in water ... ..	3.80
Fats ... ..	2.50
	<hr/>
	100.00

The microscope demonstrates that it contains four distinct farinas, one of which is remarkably rich in flesh forming materials,

From the analysis it is evident that this food is a valuable product for the use of invalids, and is prepared with the greatest care from good materials. The food has been subjected to some roasting or baking process, which not only makes it more easy of assimilation, but, from the great dryness, must add considerably to its keeping properties. It seems particularly sensitive to the action of pepsine, and when digested for an hour at 100 deg., over 90 per cent. seemed to have been rendered soluble.

#### KOPF'S EXQUISITE BISCUITS.

THESE biscuits seem to be something similar in character to the invalids' food. One important point is the absence of butter, generally present in biscuits, which in such a form disagrees with many stomachs. They are equally digestible as the food. It is stated that each ounce of biscuit is equal to four ounces of meat in nutritive value (although not meat biscuits), and this is probably correct, as the albuminates are higher than in any ordinary bread. They are delicious to the taste, novel in appearance, and from their nature would keep well in any climate.

#### KOPF'S SOUPS.

WE know of nothing introduced of late which is so likely to popularise the everyday consumption of soup among the middle and lower classes as Kopf's preparations. With these tins of consolidated soup in the house, an excellent and nutritious soup—Julienne, Scotch broth, hotch-potch, green pea, lentil, or Erbswurst—can be instantly made for three persons for the small outlay of fourpence. In saying this we are not advancing a theory but a practical fact which we have tested in our own household; and, in expressing a hope that they will come into universal use both in hospitals and private houses, we simply echo the opinions of Sir Henry Thompson, Dr. Letheby, Dr. Pavy, and other physiologists that soups of this class are invaluable, because the form of the food is one in which the nutriment is readily accessible and easily digested.

#### HAZELINE.

MESSRS. BURROUGHS, WELLCOME, & Co.'s preparation of "Hazeline" is an elegant and admirable substitute for arnica in all those cases where the latter remedy is usually prescribed. It possesses advantages over arnica, however, that are certain to recommend its use. We have found it especially serviceable employed as an embrocation in muscular rheumatism; and, particularly, when used as a mouth-wash for hardening tender gums, in a patient who had for many years tried numerous remedies in vain. The substance consists of an alcoholic extract of *Hammamelis virginica*, which has long been recognised as a valuable astringent remedy; in the treatment of hæmorrhoids it yields good results also. The preparation is pleasant to use, cleanly, and permanent.

#### FLORIDA WATER.

THE valuable properties of Florida water, as a toilet requisite, have been long recognised by ladies; and Messrs. Murray and Lanman's preparation, as now introduced to this country by Messrs. Burroughs, Wellcome, and Co., is an improved form of the perfume, which we can highly recommend for its exquisite fragrance. It is quite equal to the finest Cologne water as a scent, while being at once considerably less expensive to purchase, and possessed of greater hygienic properties. In the sick room, and the bath, its use is peculiarly grateful, and in every way it will be found to serve the purposes of the best perfumes, without producing any of the unpleasant effects, which often follow the employment of the latter for any great length of time.

#### McKESSON & ROBBINS' CAPSULED PILLS.

THE art of pill-making has reached a perfection that, a few years ago, no one would have anticipated; the beautiful sugar-coated, pearl-coated, and other machine-made pills being an immeasurable improvement on the old rough,

hand-made boluses that were in common use not so very long ago. Even these are, however, behind the latest novelty introduced in this direction by Messrs. McKesson and Robbins, of New York, and supplied by Messrs. Burroughs, Wellcome, and Co., of Snow Hill, London. These new pills are ovoid in shape, and contained in a capsule of pure gelatine, which is almost immediately dissolved on swallowing, thus liberating the contents for solution and absorption in the stomach. Any formula can be manufactured, those kept in stock being the most ordinarily ordered preparations. We have seen nothing recently in the way of new medicines to compare with these elegant articles, either in efficiency or in appearance. They are adapted for lengthened preservation by their protective covering; this also effectually conceals the taste of the enclosed medicine during deglutition, which latter, too, is materially assisted by the special shape of the pills. There can be no doubt that when generally known, their improved shape and method of preparation will cause them to become general favourites.

### Literature.

#### A MANUAL OF OPHTHALMOSCOPY FOR THE USE OF STUDENTS. (a)

MR. JEAFFRESON, of Newcastle, has thought fit to publish a translation of Dr. Dagnenet's "Manual of Ophthalmology," and of which the latter in his preface says is simply "a continued resumé of lectures he attended." With a somewhat extended field of observation and a well established reputation in eye surgery, we should have expected to be called upon to notice an original treatise rather than a translation. We certainly fail to see the gap it is expected to fill in the elementary literature of the ophthalmoscope. The author, however, has nothing to complain of, since in his translator's hands his manual receives many improvements and additions that he will admit enhances its value, its scope, and its usefulness as a text-book for students.

The opening chapter explains the more important facts connected with light, its action on lenses, and from this we naturally pass to the theory of the ophthalmoscope. In this department of ophthalmology the labour bestowed by the late Dr. Rainsay can scarcely be surpassed or excelled. We are told by the author that the ophthalmoscope was invented in 1851 by Helmholtz. Without wishing to detract from the merits of this physicist, we may say that he merely broached the idea for the present form of instrument, for Helmholtz's invention consisted merely of a bundle of thin strips of glass set at an angle of 45°, which was of no practical value in the examination of the internal eye. The first ophthalmoscope made in London, in 1851, consisted of a small rectangular brass box open on the front side, its back being pierced, and a small central hole left before which was placed a slightly concave mirror, this also having a smaller hole scraped off corresponding to that in the box. A small oil lamp occupied one portion of the box, which served for illuminating the patient's eye. This proved a successful and portable ophthalmoscope, and requiring no darkened room for its employment. This form gave way to the present handy concave mirror and bi-convex lens, as first suggested by Brucke. Facts of the kind, although quite unimportant, are very liable apparently to be forgotten.

The author's directions for the use of the instrument are practical and very necessary, whilst those given for the measurement of the visual field might have been rendered more useful. We look in vain for a description of a useful invention of Mr. Jeaffreson's, and which in practice we have found surpass either Foster's or Wecker's. The clinical method of dealing with the complex problems of visual disturbances occupy, as they should, by far the larger portion of the treatise. Considering the care with which the translator has fulfilled his part of the work, the manual may be accepted as a reliable introduction to the study of ophthalmoscopy.

(a) "A Manual of Ophthalmoscopy for the Use of Students." By Dr. Dagnenet. Translated by C. S. Jeaffreson, F.R.C.S. London: Churchill, 1880.

### DEMONSTRATIONS OF PHYSIOLOGICAL AND PATHOLOGICAL CHEMISTRY. (a)

DR. ROLFE'S demonstrations in "Physiological and Pathological Chemistry" fill an undoubted blank amongst text books for students. It has long been felt that a suitable manual of the kind designed for students preparing for their examinations was very much needed. It has, too, been pointed out in introductory lectures that whereas the student acquired only a slight knowledge of chemistry, he should be required to go further, and show that he possesses a sound practical knowledge of physiological chemistry, and the methods of employing chemical tests for himself. The handy volume before us shows how this kind of work can be accomplished. Its pages are replete with useful and practical details. Important chemical and physical characters and reactions of the proximate principles are furnished. Following on are the composition and action of the digestive fluids, and the products of decomposition, together with the chemical characteristics of blood, milk, the solid tissues, &c. The last chapter is devoted to the demonstration of the quantitative analysis of urine, and this is made instructive and highly practical. Dr. Rolfe has also added some of the more elaborated processes for the examination of urine; and numerous microscopical drawings are given to meet the requirements of more advanced students, those preparing for the higher examinations of the universities and the Fellowship of the College of Surgeons. A copious index is added, which will be found to facilitate references. On the whole this handy volume may be pronounced an excellent text-book for students.

## Correspondence.

### THE SCHEME OF EDUCATION AND EXAMINATION, ROYAL COLLEGE OF SURGEONS IN IRELAND.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Please insert some brief comments on the professional examinations of this Scheme, and on the remarks of your eminent correspondent and yourself. The measure, which imperils the existence of the College, has not been, as you state, unanimously adopted, fair minorities opposed it at various stages, nor has it received the Royal assent, which thanks to our good old charter, is requisite.

Two evils are attacked—1. That the student idling the first two, is not tested in professional knowledge till the end of his third session, and that within a month after he has passed his first, he may pass his final, examination. A reasonable remedy would be to insist on at least the interval of a year, during which courses in practical surgery and medicine should be thoroughly pursued. That the amount of scheming and idling is so enormous as depicted by the obstetrician, of whom the whole Irish profession is justly proud, and by yourself, I deny, for the sake of brevity omitting proofs, but pitting my twelve years' experience as a grinder, and fourteen as professor, against Dr. Kidd's acquaintance with school work which was antecedent to 1858, and your information, which must be indirect, as you have never been connected with a medical school.

2. That credit for school fees is largely given. This is scarcely a collegiate grievance; however, under the scheme the needy student or the "apprentice-farmer" could procure the yearly certificates by means of promissory notes. A compulsory annual registration of certificates from all matriculated students would be a sufficient remedy.

The essence of the scheme lies in the *four* professional examinations, one at the end of each year, which must be passed before the student can begin the next year's curriculum.

Such a system is in theory good, and may be adopted when anything like uniformity of education and examination is enforced amongst all or even a majority of the nineteen licensing bodies. On the 29th of last month how was the principle received by the Medical Council? Our representative, and our President (crown member) supported it, while two Crown members, seven elected by corporations, and five by universities opposed it. The opinions of such men as Sir J. Paget,

(a) "Demonstrations of Physiological and Pathological Chemistry." By Charles H. Rolfe, M.A., M.D. Cantab, &c. Bogue, 1880.

Drs. Pitman, Bradford, Humphry, Storrar, Haldane, Spence, Orr, Turner, Pettigrew, Smith, and Banks, speaking for such bodies as the Colleges of Surgeons London, Edinburgh, and Glasgow, the three Colleges of Physicians, the Apothecaries' Society, and the Cambridge, London, Edinburgh, Aberdeen, Glasgow, St. Andrews and Queen's Universities, would have me had I been hitherto an enthusiast for the scheme. Of the converted four remaining licensing bodies not represented in this division, three are surely unimportant, and the fourth is no rival of ours owing to the antecedent Arts degree. In the discussion Mr. Teale proved that provincial students and seniors proceeding under other curricula could not be expected to undergo yearly examinations in the metropolis.

In no other body, nor in the programme of our great rival of the future, the Royal Irish University, are there more than two *professional* examinations for the practice qualification, and such is the number recommended by the Medical Council.

Rejection after any one year will really shut out a student for a year from practical efforts for improvement, as parents will not bear the expense of dissections, hospitals, &c., when no credit for attendance on them could be gained, and on the grinder alone he will have to rely. The student is not relieved from scientific for practical subjects, as anatomy is to be worked at and examined on each of the four years.

The expense of the student will be increased as, at least, three years must be spent in Dublin, or more if any rejection is suffered. No credit is given for attendance at provincial hospitals. There further will be a pharmacy fee and higher charges by private teachers for much greater work.

The examinations will cost the College at least one-third more, for the examiners will have to devote, at least, twice as much time, and examiners in physics and midwifery will have to be appointed. The examiners for the midwifery diploma cannot act for the letters testimonial. To procure a sufficient surplus of examiners it will be necessary to alter the laws which restrict the selection to Fellows and those who do not teach.

The Royal Commission now sitting will enforce some plan for the more frequent examination of candidates on like terms for all bodies, and surely it is expedient for us to wait till then. The interests of surgical colleges are not likely to suffer, seeing that four of the five medical commissioners belong to them.

Omitting reference to details which will be discussed at the annual meeting on June 4th, I conclude by expressing my conviction that such a scheme would quickly reduce our candidates by one third, other bodies keeping open by two professional examinations under less rigid rules, and our doors being closed for final qualification from October to April.

I am, &c.,

May 21, 1881.

E. D. MAPOTHER.

### DISPUTED POINTS IN THE PATHOLOGY OF SYPHILIS—TREATMENT OF TERTIARY SYPHILIS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—There seems to be a very general consensus of medical opinion in Europe and the United States at present that mercury is extremely useful in the treatment of the primary lesion and the secondary or eruptive period of syphilis, a period which may roughly be said to last for some eighteen months. But there is some doubt as to whether mercury should be given in the tertiary period of the disease, and I therefore propose to examine what has been said on both sides of this all important point in therapeutics.

As a general rule it seems to me that nothing can be more injurious than courses of mercury in syphilitic affections of the bone or destructive ulcerations of the soft parts resulting from gummy infiltrations. In sloughing of the throat, which is one of the most common tertiary affections, I hold it to be quite bad practice to give mercury, whilst iodide of potassium will, when given in large doses, prove rapidly curative in the immense majority of cases. Tertiary affections require good diet and other favourable hygienic appliances, and not mercury, which is in such cases greatly opposed, I think, to the cure of the disease.

The remedy *par excellence* of tertiary syphilis is iodide of potassium. Mr. James Lane tells us (Lectures, 1881, p. 85) that it was Dr. R. Williams who, in 1831, first used this inestimable remedy for syphilitic bone disease in St. Thomas's

Hospital. Dr. R. McDonnell, on the other hand, assigns the honour of the discovery of its virtues in tertiary syphilis to Mr. Wallace of Dublin, who wrote about it and its dose in 1836 in the *Lancet*.

Iodide of potassium has, I think, little influence on the early stages of syphilis. It is held by many able writers that it is of use in tertiary syphilis merely to remove existing grave symptoms, but that it does not cure or prevent relapses, which they allege will require the aid of mercury to prevent them. This is not my experience at all. Tertiary syphilis certainly tends to reappear over and over again, but mercury has not seemed to me to prevent these relapses, or render them less severe, whilst it may do much harm if given in large doses. It will not unfrequently do away with the advantages of the iodide of potassium, and cause soft nodes to suppurate.

Iodide of potassium is also most useful in syphilitic cachexia, and should be continued a long time in slowly increasing doses. Iodide of sodium is useful in rare cases, when iodide of potassium causes its peculiar symptoms (coryza, hydroc, &c.).

I am Sir, yours obedient,  
C. R. DRYSDALE, M.D.

May 19, 1881.

#### NEW SCHEME OF EDUCATION AND EXAMINATION OF THE ROYAL COLLEGE OF SURGEONS IN IRELAND.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In my last letter I showed that the institution of sessional examinations is the essential part of the new scheme, and I enumerated some of the more important advantages that would attend its adoption. In a note you very clearly and pointedly drew attention to one of the abuses attendant on the present system, an abuse to which I myself alluded in my letter of the 7th inst., but on which, after your remarks, it is not necessary that I should further dwell. The whole question of sessional examinations as compared with one grand final examination, was so admirably put by Sir Henry Marsh in his "Letter on the Proof Report of the Committee of the Faculty of Medicine of the London University," that, at the risk of trespassing on your space, I must ask leave to quote his remarks.

"My next proposition," he says, "should be to have annual examinations on fixed, definite, and limited subjects, and these necessary ones, and no large final; and as it now is, boundless examinations. I think this *grand* examination most pernicious in its effect on the student's mind, and ill-calculated to effect its intended object—that of being a test of proficiency. The object now before a student's mind is to be well prepared for this great and dreaded examination, and not, as it should be, to know and treat disease. The science of the treatment of disease can only be learned *peu a peu*. The student's proficiency should also be ascertained step by step. This would be best ascertained by yearly or half-yearly examinations. Here with us this great examination, on which a young man thinks his prospects and success for life depend, is most injurious to the mind and the whole course of study. Its wide range gives a hopelessness as to being fully prepared, and the health of many has been permanently impaired. The pupils are at the mercy of the examiners, some of whom, it uniformly happens, are blockheads. Time and health are wasted in useless studies to prepare, not for practice of one's profession, but to answer either book questions, or fanciful and often absurd ones. Those who are most flippant, and least disturbed by *mauvaise honte* are, I have found in many instances, the best answerers, but the really worst informed. Grinding and cramming thrive; no one ventures on this awful examination without bringing grist to the mills of the grinders. In one word, nothing can be worse than the present system of our great and closing examination as now conducted. Indeed, after the fullest consideration, there are, I think, great objections to it however managed. I think the system of *gradual* learning tested by successive examinations at short intervals far preferable."

This "hopelessness of being fully prepared," of which Sir Henry Marsh spoke as arising from the wide range of subjects in which the student is liable to be examined, in

the one great final examination, leads directly to the system of cramming. For though it is not possible to be fully prepared for an examination in such a vast extent of subjects, it is necessary to appear to be so. Hence recourse is had to the grinder, and parrot-like answers to a certain series of questions is learned, which may serve the purpose of an examination, but no other. Such a system of cramming must be carefully distinguished from a proper system of private or tutorial teaching. In this a certain subject is prescribed to the students which they are expected to study, and then to go to their teacher who examines and cross-examines them in reference to it, correcting their misconceptions, or leading the class to correct one another. By this method the amount of study given to the subject is tested, as well as the clearness with which it has been apprehended, and the powers of retention and memory of the student. For teaching the elements of a science there can be no better method. It has the further merit of teaching the student to arrange his ideas, to have his knowledge ready for use when called on, and to express his thoughts in words, and so it relieves him of much of the *mauvaise honte* which afflict many when undergoing an examination, and the training they undergo is of use to them throughout the whole of their subsequent career. The late Professor Whewell, in a valuable essay, called this "Practical Teaching," in contra-distinction to lectures which he called "Speculative."

In the practical mode of teaching the learner has, he says, "not merely to listen, but to do something himself. Not merely to receive, but to produce his knowledge." A well conducted system of sessional examinations partakes in a large measure of this character of practical teaching, and differs in this respect from the one grand examination, which is merely detective and punitive. In another letter I hope to show how the details of the scheme may be expected to work.

I am, Sir, yours, &c.,  
21st May, 1881. GEORGE H. KIDD.

#### THE CASE OF MR. PROSSER, OF BIRMINGHAM.

WE have been requested to publish the following correspondence:—

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—By direction of the President and Fellows of this College, I request you will give publicity to the accompanying correspondence between this College and the General Medical Council.

One of the licentiates of the College having suffered much, professionally and socially, in consequence of the conduct of another registered medical practitioner, the College were anxious to uphold the dignity of their licence and to advance the interests of their licentiates, and accordingly they took steps to bring the facts of the case before the General Medical Council.

It was, therefore, with much regret that the College learned that, by the "Standing Orders" of the Council, the subject was delegated to the English Branch Council, and that it was never considered at all by the General Medical Council.

I have the honour to be, Sir,  
Your obedient servant,  
J. MAGEE FINNY, M.D.,  
Registrar.

King and Queen's College of Physicians  
in Ireland,  
Dublin, May 12th, 1881.

No. 1.

King and Queen's College of Physicians  
in Ireland,  
Dublin, April 8th, 1881.

DEAR SIR,—By direction of the President and Fellows of the King and Queen's College of Physicians in Ireland, I beg to lay before the General Medical Council the following brief statement of what appears to the College to be "infamous conduct in a professional respect," on the part of Richard Albert Shipman Prosser, M.R.C.S. Eng., L.S.A. Lond.

At an inquest held on the body of Ellen Alley, at the

Coroner's Court, Moor Street, Birmingham, on the 10th June, 1880, Mr. R. A. S. Prosser swore to having made a post-mortem examination of the body, and to having examined the kidneys and all the abdominal viscera. He also swore that the kidneys were healthy, and he gave it as his opinion that death was in part caused by the negligence of the medical practitioner who had attended her the day but one before her death. On this evidence, Mr. Edward Hyacinth O'Leary, L.K. & Q.C.P.L., was committed for manslaughter by the coroner.

A subsequent post-mortem examination having been conducted by James MacLachlan, M.D., and Robert Saundby, M.D., it was shown that the kidneys had not been disturbed from their place, and that the examination of the other viscera had been most incomplete. When this fact was disclosed before the stipendiary magistrates' Court, on June 23rd, the prisoner was discharged; and the grand jury threw out the bill at the Warwick Assizes.

I am further directed to convey to the General Medical Council the opinion of this College that should the facts be found on inquiry to be as stated above, the conduct of Mr. Prosser, socially and professionally, deserves to be termed "infamous;" and to request the Council forthwith to make due inquiry into the above-stated case, with a view to exercising the powers conferred by Sect. xxix., Medical Act (1858), as to erasing from the Register the name of Mr. Prosser.

I have the honour to be, dear Sir,  
Your obedient servant,  
J. MAGEE FINNY, M.D.,  
Fellow and Registrar.

The Registrar of the  
General Medical Council.

No. II.

General Medical Council Office,  
315 Oxford Street, London, W.,  
May 2, 1881.

SIR,—I am directed to inform you that, pursuant to Chapter 14 of the Medical Council's "Standing Orders," your letter of the 8th ultimo, in regard to Mr. Prosser, has been considered by the English Branch Council; and that the said Council, at its meeting on the 27th ultimo, passed thereon the following resolution:—

Resolved—"That the Branch Council for England direct the Registrar to acknowledge the receipt of the letter from Dr. Finny, and to state that the case does not seem to the Council to be one in which they could usefully take action."

I am, Sir,  
Your obedient servant,  
W. J. C. MILLER.

J. M. Finny, Esq., M.D., &c., &c.

PREVENTIBLE DISEASES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Recently at the London Institution Professor F. de Chaumont, in treating of sanitary insurance made certain statements of a most serious character. He pointed out that of the 700,000 deaths recorded annually by the Registrar-General, a very considerable proportion thereof was due to causes that might be removed by timely legislation and sanitary control. The diseases of a preventible nature are thus classified:—

	Death-rate.
Consumption ... ..	70,000
Diphtheria ... ..	3,500
Diarrhoea ... ..	33,000
Enteric fever ... ..	11,000
Scarlet fever ... ..	25,000
Respiratory organs ... ..	100,000
Total ... ..	242,500

Now, the several classes of diseases above enumerated, the Professor states to be "propagated by foul air and foul water," while he dilated on "the fearful extent of mortality and sickness caused by defective sanitary arrangements."

While a Sanitary Assurance Association has lately been formed with the object of inspecting the sanitary arrangement of the dwellings of members, and granting certificates,

a movement has likewise been made by notable persons, interested in the public health question, to promote sanitary legislation by the amendment of the Public Health Act, and the appointment of qualified inspectors to guarantee, by frequent inspection, that the sanitary arrangements of every building are constructed and maintained in proper order.

So far, so good. One thing further, however, remains to be done. We can never expect to be free from recurring epidemics of divers kinds so long as our overcrowded suburban cemeteries are suffered to receive more tenants. Greater London is growing daily in extent, so that where once we had the air of the country, and where only pastoral cries were to be heard in the streets, we now find dense populations and a tainted atmosphere. Much sickness obtains in neighbourhoods where public and reeking grave-grounds lie adjacent; while the danger to the health of the community by the pollution of water alone, is sufficiently serious to demand attention.

In his final letter to the *Times* Mr. Seymour Haden urged that our seething suburban cemeteries should be closed, and suggested that "in negotiating with the present cemeteries, account would, of course, be taken of the sales they have already effected 'in perpetuity,' and of the very little land available for any useful purposes whatever, that they have yet to sell." Meanwhile, he recommends the London Necropolis at Woking, with its thousand acres of excellent land as admirably suitable for all the purposes of a cemetery, and capable upon the primary condition I insist upon of insuring the resolution of the body, of effecting 100,000 interments per annum for ever. The Act of incorporation of Woking Cemetery providing also a separate grave for each body. With such a capacious and beautifully-situated "Home for the Dead" not more than three-quarters of an hour's ride by special railway from the private station at Westminster Road, it seems me as singular that something cannot be done to arrest further contamination of the metropolis by its proximity to unhealthy and super-saturated grave-grounds, which ought to have been closed years since. I am, &c.,

MEDICUS.

PATENT MEDICINES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—With the advance of medical science—*sic venia verbo*—the field of operation for quacks has gradually been restricted. While formerly every conceivable disease, or rather every conceivable name of disease was the subject of their solicitude, the fortunate possessors of secret remedies have at present to confine themselves almost entirely to "purifying the blood, and to curing nervousness, constipation, pimples, baldness, consumption, gout, and asthma." With some capital at their disposal, and by its very judicious investment, these individuals soon convince an enlightened public opinion, and succeed beyond expectation in attaining the end desired. Morally, as well as legally, such practice is solely one of obtaining money by false pretences, inasmuch as they profess to remove by means, known to themselves alone, certain conditions, of which they are necessarily profoundly ignorant. If a toothless crone, who had taken to prophesying, were to predict to the kitchen-maid that she would soon be married to a handsome young fellow, which event did not happen, the disappointed maiden could have the satisfaction of seeing the prophets imprisoned as a rogue and vagabond. And yet, who can deny that the tender interviews between the policeman on the beat and the buxom maid may not have suggested the elements of the prophesy to the humble imitator of Zadig. But the beneficent quack does not confine his game to the kitchen, but ascends to the drawing room, alleging that he alone is capable of removing piles, and the three F's (fat, freckles, and forty) so dreaded by females, and he escapes, not only unhurt, but is enabled to accumulate a fortune by merely bribing the Government, who, by the sale of stamps, obtain the trifling sum of over one and a-half millions sterling. It has always appeared to me a most glaring injustice to drag an unfortunate chemist before a police court, and to fine him £5 and costs for prescribing over the counter for slight ailments, that being an accepted and universal pursuit of the trade. I shall not stop to inquire whether chemists are competent judges as to what are or what are not "slight ailments." If they, instead of giving advice to individuals, would express their opinion in more general

terms, and print their labels thus:—Mr. Tom Jones' diarrhoea mixture cures all forms of diseases, blues, &c.—they would save themselves the vexatious interruption of their business by appearance in a police court. It is a great pity that qualified practitioners are not entirely free from blame in this matter. When licensed quackery heralds the discovery of some remedy, and duly invests it with seeming scientific truth, there may be some excuse for regular practitioners employing and recommending these nostrums. Unfortunately there is so much mental inertia abroad, that the public do not readily discover the grain of truth in these seductive statements. Consequently patent medicines of the most absurd character are heralded by the certified reports of the wonderful cures wrought by the consulting surgeon to the Hospital for Grown-in Toe-nails (Chairman his Grace the Duke of Whitechapel), Member of the Faculty of Sorcerers, and late senior physician to the Court of Timbuctoo, author of several learned works published by the Improved Curl Paper Company, and others. Surely, no one who has the slightest regard for himself and for his profession ought to recommend remedies invented by quacks, and though a healthy empiricism may not be altogether dispensed with, there ought not to be any use made of remedies of unknown composition and unknown action. Enough mischief is done by the established preparations contained in the Pharmacop. Britan. and the Pharmacop. Elegans (sic). I am strongly of opinion that a little homoeopathy would be a capital thing for the treatment of this *morbus medicinalis*, yet, in asthma, physicians who would otherwise scorn to stoop so far, constantly and universally employ patent medicines. When some of the daily papers recently reported that the late illustrious Lord Beaconsfield had derived benefit only from a quack remedy called "Nimrod's cure for Asthma," shame and indignation at the insult offered to our profession was diminished on reflection that perhaps the account may have been made by an interested reporter. But the *British Medical Journal*, the following week, has it on authority that such preparation had been used. There were not wanting those who had frequently already raised their voices against such practice. I do not know whether homoeopathy or allopathy suggested the remedy, but let us hope now that the discovery has been made, that even now both illustrious and non-purpled patients will be spared the injury inflicted upon them by the successive application of nostrums contained in the trade lists of wholesale chemists.

Your obedient servant,  
A PHYSICIAN.

Medico-Legal Intelligence.

FEEs FOR RE-VACCINATION.

ON Wednesday last, the Court of Queen's Bench in Ireland delivered judgment upon the case of Dr. Duncan v. the Omagh Guardians; an action taken by Dr. Duncan, the Dispensary Medical Officer of Fintona District, at the instance of the Irish Medical Association, for the purpose of establishing the right of public vaccinators to re-vaccination fees under the Act recently passed.

The plaintiff, claimed from the defendants £3 12s, for 36 cases of successful vaccination; £58 2s. fees for 581 cases of re-vaccination, irrespective if such vaccination were successful or not; £4, fees for 40 cases of successful vaccination; £3 6s. for 33 cases of re-vaccination, irrespective of whether such vaccination were successful or not. The guardians demurred to the claim for re-vaccination, on the ground that the plaintiff was not entitled to be paid unless the re-vaccination was "successful."

The words of the Act which was promoted in 1879 by the Irish Medical Association, and under which Dr. Duncan claimed, were especially framed to take in re-vaccination and are as follows:—

"The Guardians shall pay to every such medical officer for every person successfully vaccinated or every person re-vaccinated by him within his dispensary district the sum of 2s."

Acting on the advice of the Local Government Board the guardians contested the claim.

Mr. Justice O'Brien delivered the judgment of the Court, and said that the question turned on the true construction of the 6th section of the Vaccination Act of 1879. In the argument the

Acts of 1858 and 1863 had been referred to, but in these there was no mention made of re-vaccination. Provision was made in the 5th section of the latter act, that instead of £1 for every twenty cases, the guardians should pay 1s. for every successful case of vaccination reported to the dispensary committee of management. By the Act of 1879 the fees were increased to 2s. "for every person successfully vaccinated, or every person re-vaccinated by him within the dispensary district." The guardians contended that the word "successful" applied to and governed the word "re-vaccinated," and that the medical officer was not entitled to payment for either of such operations, except he was successful. But the rule of construction was that the meaning of the words used should in the first instance be adhered to and effect given to those words, except the doing so should involve inconsistency with what was the declared intent of the Legislature. The learned judge thought it clearly appeared that the Act of '79 dealt with the case of an operation on a party who had been previously vaccinated as different from a case in which the operation was performed for the first time. There was nothing repugnant to the intention of the Legislature in holding that the word "successful" did not refer to re-vaccination, while the contrary construction would be attended with results that could not be supposed to be the intention of the Legislature. Judgment should therefore be for the plaintiff.

Judge Fitzgerald concurred, but said as the case was one of doubt, and as it affected the whole country, probably the guardians would think right to take it further:—To the Court of Appeal where everything was understood (laught.r.)

Mr. Justice Barry also said the question was one of doubt, but he thought the only rational construction was to distinguish between vaccination and re-vaccination in the last Act.

Royal College of Surgeons of England—The following candidates having passed the required examination for the diploma, were admitted Members of the College on May 16th:—

Bassett, W. F. Prichard, M.B. E.I.	Vervey, Louis, M.D. Leipzig
Burton, Wm. Henry, M.B. Toronto	Wells, Charles, M.D., Q.U.I.
Grinling, John Champion	Willett, Georg; Gilmore Drake
McCormick, Alexander, M.B. Ed.	Woodruff, John Winthrop

The following were admitted members on Tuesday, May 17th:—

Batson, Robert Sewall	Newsholme, H. Wilkinson
Branson, G. A., L.R.C.P. Ed.,	Pritchard, Owen, L.S.A.
Green, Harry, L.S.A.	Ramden, Albert
Keys, Elias,	Thane, Philip Thornton
Maitland, Alfred Derwent	Thornton, Bertram
Minchinton, Henry James	Willis, Arthur, L.S.A.,
Mivart, F. St. George, L.R.C.P. Ed.	Willis, Arthur Keith

The following gentlemen were admitted on May 18th:—

Alexander, Frederick William	Coutts, Joseph Alfred
Chard, R. A. Selway	Currie, Oswald James

Royal College of Physicians in Ireland.—At examinations held on the 9th inst., and succeeding days, the under-mentioned obtained the licences in Medicine and Midwifery of the College:—

Browne, Augustus James Arthur	Jacobs, William Wall
Carroll, Louis John Patrick	McDermott, Patrick Andrew
Clarke, Walter John	McGill, Harry Strickland
Flynn, Edmond Francis	Maw, John Henry Cornelius
Garland, James.	Monray, Georg; Cathcart
Gloster, Edward	O'Keefe, William Joseph
Higgins, Thomas	Whitehead, Thomas Kay

The following Licentiates have been admitted members:—

Dane, Arthur Henry Cole, Surg.	Marques, Lourenzo Pereira
Bombay Army	Nugent, Edward Joseph
Lamb, H., Surg-Maj. A.M.D.	Whitty, Patrick J.

Royal College of Surgeons in Ireland.—At the April examinations the following obtained the licence in Surgery:—

Acheson, Howard W.	Murphy, Edmond
Baird, James A.	Nells, George
Barrett, Charles D.	Niokson, Augustus
Brady, John	O'Brien, Francis F.
Bullock, John G. W.	O'Carroll, Joseph F.
Callan, Richard	O'Doherty, Edward H.
Coollan, John P. J.	O'Doherty, Michael J.
Dempsey, Patrick J.	Fenny, John A. C.
Dunlop, John B.	Fowell, John A.
Elderton, Frederick D.	Fower Robert
Gelston, John B.	Quirke, James
Jones, Walter	Redmond, Thomas O'O
Kenna, Michael F.	Ross, Alexander
Lewis, Thomas W.	Smith, Ventry A. J.
MacKullon, James C.	Stowell, Jones C. L.
McGuinness, John H.	Tate, Robert J.
McSwiney, Claude H.	Williamson, Macnamara M.
Maloney, Michael C.	Woodroffe, August

THE week before last Dr. William Stoker and Dr. Warren, of Dublin, were presented by those of their pupils who recently passed the first half of their professional examination with two handsome pieces of plate, accompanied by an address. The students were afterwards entertained by Dr. Stoker and Dr. Warren at dinner.

Cambridge University.—At a congregation held May 21st, the following degrees were conferred: *Third Examination for the Degree of M. B.*—Part II. Examined and Approved. Class I. Coxwell, B.A., Christ's; Lapage, M.A., Magdalene; Mason, B.A., Pembroke; Tooth, M.A., John's. Class II. Birdwood, B.A., Peterhouse; Standirt, M.A., Corpus; Widmore, B.A., John's.

## NOTICES TO CORRESPONDENTS.

**CORRESPONDENTS** requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

**LOCAL REPORTS AND NEWS.**—Correspondents desirous of drawing attention to these, are requested kindly to mark the newspapers when sending them to the Editor.

**READING CASES.**—Cloth board cases, gilt-lettered, containing 26 strings for holding each volume of the *Medical Press and Circular*, can now be had at either office of this Journal, price 2s. 6d. The postal regulations not allowing the Journal to be stitched, these cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

### A STUDY OF THE PERIODS OF INCUBATION OF THE COMMUNICABLE DISEASES.

We are indebted to Dr. B. W. Richardson, F.R.S., for the MS. of his valuable and instructive paper on the above subject, which was read on Friday last before the Association of Medical Officers of Health. This paper we purpose placing before our readers in our next issue.

**DR. PINDER.**—We regret you should have any difficulty in your neighbourhood to procure copies of the *Medical Press*. Of course not one news-vendor in a hundred keep medical journals for casual sale, but any would supply this Journal regularly if ordered. Should you still find any difficulty, Messrs. Smith & Son would be glad to deliver it from their nearest bookstall.

**DR. SUNTER.**—Evidently a postal blunder.

**DR. STRETCH DOWSE'S** lecture "On the Diagnosis and Treatment of Apoplexy" received, and will appear in an early number.

**DR. C. A. OWENS.**—We hope to commence your articles "On Paracentesis Thoracis by Aspiration in Acute Pleurisy" in our next or the following number.

**MR. HAYNES WALTON** is thanked.

**DR. PEIRSON** (Scarborough).—Our opinion exactly coincides with yours; the position assumed is untenable both on scientific and professional grounds; much capital has, moreover, been made out of the circumstance which is to be deplored.

**MR. H. E. T.**—We do not insert advertisements for "Babies" Yours may proceed from a perfectly legitimate desire for adoption, but the presence of an application of the kind in an established medical journal might open up fresh ground for "baby-farming" which we have ever been anxious to suppress.

**LINCOLNENSIS.**—Paper received. Any advertisement of the kind is distinctly out of place, and reacts injuriously on the dignity of the medical profession. In this instance we imagine some over zealous friend has rushed to publish the fact that Mr. Harper has performed a successful ovariectomy. It is, however, to us, and to all medical readers, laughable to see the exaggerated importance attached to the feat by the gushing reporter. We cannot think any practitioner of standing would himself be guilty of such an outrage on propriety and usage; we prefer, therefore, to attribute it to an unprofessional hand.

**EX. COLL. REG.**—We cannot give you any positive information on the point. We have been told, however, that one college did send in six men for the examination, and that every one of them was ploughed. If you are prepared to support and verify your assertion, then we shall be quite willing to print the article. The test system is utterly futile as a proof of knowledge, and we cannot but think recent events have tended to prove it so.

**MR. PARSONS.**—The advice given so frequently is as applicable in your case as in any other. Do not think of proceeding with the technical studies until the way has been thoroughly cleared for their successful prosecution. To you this means, finish the preliminary examination, scientific as well as in arts, and then go ahead.

**THOMAS LAFFAN.**—Your letter will appear in our next.

**W. P. O'L.**—The period at which it would be allowable to occupy an infected bedroom would depend wholly upon the cubic space, freedom of ventilation, and other circumstances special to the particular case. No general rule could be given.

**BOYLE'S AIR-PUMP VENTILATORS**—We are asked to state that Messrs. Robt. Boyle & Son are at present applying their complete System of Ventilation and Air-pump Ventilators (referred to in a recent number of this Journal) to Knowsley Hall, Lord Derby's seat in Lancashire.

**CLINICAL SOCIETY OF LONDON.**—Friday, May 27, at 8.30 p.m., Dr. Wiltshire, "On a Case of Traumatic Rupture of an Ovarian Cyst."—Dr. T. C. Fox, "On Two Cases of Chromidrosis, in which a Blue-black Pigment exuded upon the Skin of the Circum-orbital Regions."—Mr. MacCormac, "On a Case of Reunited Fracture of the Olecranon Process, in which bony union was obtained by Suture of the Bones."—Dr. Sturge and Mr. God ee, "On a Sequel to a Case of Stretching of the Facial Nerve."

## VACANCIES.

Belmullet Union, Knocknolwer Dispensary.—Medical Officer. Salary, £10. Election, June 6.  
Croydon General Hospital.—House Surgeon. Salary commencing at £100, with board. Applications to the Hon. Sec before June 1.  
Drogheda Union, Monasterboice Dispensary.—Medical Officer. Salary, £110, and £20 Medical Officer of Health. Election, May 31.  
Liverpool.—Resident Medical Officer for the Township of Toxteth Park. Salary, £100 with board and residence in the Workhouse Infirmary. Applications, endorsed, to be addressed to the Clerk of the Guardians before June 1.  
Monaghan District Lunatic Asylum.—Assistant to Resident Medical Superintendent. Salary, £150, with furnished apartments, &c. Election, June 9. (See Advt.)  
North Eastern Hospital for Children, Hackney.—House Surgeon. Salary, £70, with board. Applications to the Secretary before June 1.  
Royal Free Hospital.—Ophthalmic Surgeon. Applications to be sent in before June 1. (See Advt.)  
Teignmouth Infirmary.—House Surgeon. Salary, £85, with board. Applications to the Chairman of the Board before June 1.

## APPOINTMENTS.

BALLANCE, C. A., L.R.C.P., M.R.C.S.E., Senior Assistant House Physician to St. Thomas's Hospital.  
BOLTON, E. E. N., L.R.C.P.Ed., M.R.C.S.E., Medical Officer for the Ballickmoyler and Newtown Dispensary Districts of the Carlow Union.  
COLLIER, M. P. M., M.R.C.S.E., Junior Assistant House Physician to St. Thomas's Hospital.  
CUMMING, G. W. H., L.R.C.P.Ed., M.R.C.S.E., Medical Officer for the Fourth District of the Chipping Sodbury Union.  
DODDS, W. J., M.D., D.Sc., Assistant Medical Officer to the Birmingham Borough Asylum.  
FOSTER, H. G., L.R.C.S.Ed., Medical Officer of Health for the Swaffham (Norfolk) Rural Sanitary District.  
HASLAM, W. F., M.R.C.S.E., Resident Accoucheur to St. Thomas's Hospital.  
HUDSON, G., M.D., M.R.C.S.E., Medical Officer for the Sixth District of the Beverley Union.  
JORDAN, F., F.R.C.S., Consulting Surgeon to the Birmingham and Midland Skin and Lock Hospital.  
LEWIS, F. W., M.R.C.S.E., Medical Officer for the First District of the Llandoverly Union.  
LUNN, J. B., L.R.C.P.L., M.R.C.S.E., Senior Resident Medical Officer to the new Marylebone Infirmary.  
MCGEAGH, J. P., M.D., M.Ch., Senior Assistant House Surgeon to the Public Hospital and Dispensary, Sheffield.  
SPICER, R. H. S., B.Sc., Demonstrator of Comparative Anatomy and Botany at St. Mary's Hospital, Paddington.  
BUTTON, S. W., L.R.C.P., M.R.C.S.E., Assistant House Surgeon to St. Thomas's Hospital.  
TREHERNE, F. H., L.R.C.P.Ed., L.R.C.S.Ed., House Surgeon to the West London Hospital, Hammersmith.  
WELFORD, C. H., M.B., C.M., Senior House Surgeon to the Sunderland Infirmary.  
WHITEHOUSE J., M.R.C.S.E., L.R.C.P.L., Junior House Surgeon to the Sunderland Infirmary.

## Births.

FENN.—May 19, at Richmond, Surrey, the wife of Edward L. Fenn, M.D., of a son.  
HILLS.—May 13, at Providence, Carlow, the wife of John D. Hills, J.P., F.R.C.S., M.R.I.A., of a daughter.

## Marriages.

WILSON—POLLOCK.—May 14, at the Parish Church, Baronsclown, Dundalk, John Wilson, L.R.C.S.I., L.R.C.P., to Maria, eldest daughter of the late Lr. Pollock, Cara Ville, Dundalk.

## Deaths.

BLAKE.—April 6, at Queenstown, Walter J. Blake, Surgeon-Major, A.M.D.  
BOND.—May 13, at Stoke Newington, Edward T. Bond, M.R.C.S.E., L.S.A.L., in his 84th year.  
JAMESON.—May 16, at Oakwood Lodge, Upper Norwood, Hugh Jameson, F.R.C.S., Deputy Inspector-General of Hospitals and Fleets (Retired), in his 77th year.  
M'MUNN.—May 12, at Port Royal House, Ballygoran, co. Sligo, Robert M'Munn, M.D., C.M., Glasgow.  
WHITAKER.—May 19, at North Walsham, James Fealey Whitaker, L.S.A., M.R.C.S.E., eldest son of the late James Samms Whitaker, M.R.C.S., F.L.S., aged 29.  
WOODROOFE.—May 17, at his residence, Springmount, Dundrum, of apoplexy, Richard Woodroffe, M.D., aged 47.

## Original Communications.

### A STUDY OF THE PERIODS OF INCUBATION OF THE COMMUNICABLE DISEASES. (a)

By BENJAMIN WARD RICHARDSON, M.D., F.R.C.P., F.R.S.

THE points I propose for discussion are the following:—

1. The precise application of the term incubation, and to what diseases it should be applied?
2. The amount of absolute knowledge of the period of incubation of the more common communicable diseases?
3. The differences of opinion on this subject; do they depend on fault of observation, or on the circumstance that there are, in the same diseases, varying periods of incubation, the variations being under no, as yet, defined rule?
4. If it be seen that there are differences of periods in the same diseases, upon what may such differences depend?
5. The practical lessons which arise from the facts we at present possess, and the extent to which our knowledge may be rendered available in regard to direction in the prevention and treatment of disease?

The period in the course of a disease to which we should apply the term incubation, and the diseases to which we should strictly apply the term, are the two first points deserving our consideration.

At the outset this may seem to be a subject easy enough to settle, but when the mind comes down to it, it is not at all easy. We simplify somewhat by saying that the term is to be limited to those instances in which, after a certain specific poisonous particle has been taken into a living body, certain indications of the action of that specific poisonous matter has been manifested. We say that the period between the introduction of the poisonous particle, and the appearance of manifestation of action, is the period of incubation, but we fail to be unanimous on the

question—What is the accepted first sign of such manifestation? Is that first sign any sign, or one particular sign? Is it a local sign, or is it a general or systemic sign? If, again, it be a systemic sign, is it one systemic sign, or two, or more, or one of many?

Let me give a small illustration of what I mean. The older practitioners, when they inoculated for small-pox, ruled that the orange-coloured eruption round the needle-puncture came on from the fourth to the fifth day, followed by a distinct vesicular rising, with pain in the axilla, on the seventh day, and systemic pain—pain in the back and limbs, and head—with rigor and fever on the ninth or tenth day, and appearance of a general eruption on the eleventh day. What here was the period of incubation? Was it from the time of the insertion to the occurrence of pain in the axilla, or to the rigor with pain in the back and the limbs, or to the appearance of the general eruption? In vaccinia, in these days, we meet with this question—Is the appearance of the local eruption at the point of puncture, and the formation of the vesicle, to be counted as the end of the period of incubation; or is the after fever, or other systemic symptom, to be taken as the close of the period? I have known a case of vaccinia in which there has been no indication of effect at all, except the local manifestation. In such a case am I to say that the local change is sufficient when it is vesicular, when it is pustular, when it is maturative? Or am I, in such a case, to say there has been no period of incubation at all; that the whole process is abortive, and that the vaccinated is therefore either insusceptible or unprotected? I take this illustration because it is so very definite, because we know that the poisonous particle was inserted at a certain time, and can therefore be traced from that time into effect. When we come to the question of reception of the poison by a means less definite, we have more reason than ever for some decided rule. In scarlet fever what shall guide us? Shall it be the actual fact of a change in temperature? If so, shall that be the preliminary depression of temperature? Or, shall it be the first elevation of temperature that follows depression? Or, shall it be pain, or shall it be eruption? Until we can agree on these points, there can never be accuracy in our records.

(a) Read before the Association of Medical Officers of Health, Friday, May 20th, 1881.

I have studied very closely for two years past the various sides which this question presents, and by exclusion I have, for the moment, come to an opinion I am about with submission to offer to you. I would exclude all mere local manifestations, because I see that they may be presented and may not indicate that the disease has been incubated, in the full sense of that term. I exclude pain, local or general, because that might be due to other causes than the action of the poisonous material, or if it were due to that it is too much of a subjective symptom to be reliable. I exclude eruption because it may not be present, although the disease may be incubated, or it may be looked over, or it may be transient and therefore not detected. I exclude mere rise of temperature because that alone might not be detected at its origin, but might have been long present before it was detected. But I accept as the safest of all the phenomena indicating that the period of incubation is declared, that sudden vibration between cold and heat, which we call chill or rigor. This is at once a subjective and an objective phenomenon. The observer sees it in the pallor and coldness and shivering, and reactive fever of the affected. The subject of the attack is easily able to define its precise period of commencement and its course. Moreover, of all the phenomena it is the most certain. In my experience I never knew a case of a communicable disease that was not preceded by chill. In cholera, in which it might perhaps not be expected by those who have not seen the disease, according to my experience in the two epidemics I have witnessed, it was always present. "The chill came on," at such a time was nearly the invariable sentence which fell from the lips of the stricken who were able to describe their own sufferings. There is, moreover, a physiological reason for accepting chill or rigor as the indication that the poisonous particle has taken effect. The phenomenon is the natural indication that the disunion of normal action between the nervous and the vascular systems has taken place. It is like to the convulsive tremor which occurs when at a precise point during loss of blood the break between blood supply and nervous supply is interrupted. It is still more like the tremor which is invariably produced when an alkaloidal poison like nicotine shows its diffusion through the body, and, as we would say, declares that the period of its introduction is finished. If we had an alkaloid like nicotine which would increase in the body and by its increase diffuse up to the pitch of physiological action, we should rule that the incubation was finished when the tremor declared it. Granted then, that a disease runs a definable course, I should take the first rigor or chill as the first sign of the disease, and should accept the intervening period between the introduction of the cause and the development of the chill, as the true period of incubation.

In the next place we may study under the present head the diseases to which the term period of incubation may be properly applied. On this point there is nothing strictly definite amongst the members of the profession. We are probably pretty unanimous in assuming a stage of incubation to the following common affections, 25 in number:—

- |                          |                      |
|--------------------------|----------------------|
| 1. Plague.               | 14. Relapsing fever. |
| 2. Cholera.              |                      |
| 3. Malignant pustule.    | 15. Variola.         |
|                          | 16. Vaccinia.        |
| 4. Scarlet fever.        | 17. Varicella.       |
| 5. Diphtheria and croup. | 18. Measles.         |
| 6. Influenza.            | 19. Rotheln.         |
| 7. Pertussis.            | 20. Typhus.          |
| 8. Glanders.             | 21. Typhoid.         |
| 9. Erysipelas.           | 22. Mumps.           |
| 10. Farcy.               | 23. Malarial fever.  |
| 11. Grease.              |                      |
| 12. Dengue.              | 24. Syphilis.        |
|                          | 25. Hydrophobia.     |
| 13. Gonorrhœa.           |                      |

But there are some others on which we should not be so unanimous, as for instance—

- |                      |                       |
|----------------------|-----------------------|
| Catarrh.             | Remittent fever.      |
| Puerperal fever.     | Intermittent fever.   |
| Pyæmia.              | Choleraic diarrhœa.   |
| Hospital gangrene.   | Cerebro-spinal fever. |
| Sloughing phagedæna. | Carbuncle.            |
| Phagedæna.           |                       |

These last-named diseases all require to be more carefully observed in respect to period of incubation and first indication of defined symptoms before they can be proved to have a stage of incubation at all, and before, therefore, our knowledge can be said to be perfect in respect to them.

I would now venture to indicate what are the nearest approaches to the true periods of incubation in the different diseases which present an undoubted stage of incubation. In preparing the chapters of a work on preventive medicine, I thought it worth the trouble to collate the views of all our best authorities on the subject, old and modern, and to bring them into a condensed form, adding thereto what I had myself observed from natural facts.

Without loss of time I will state the results in brief form, but I must not let the opportunity pass of expressing how deeply we are indebted to Dr. Squire for the insight he has shown in dividing the communicable diseases according to their periods of incubation. Following closely his admirable plan, but somewhat extending it, I divide the diseases attended with stages of incubation into five groups:—

*Shortest.*

a. Shortest Stage of Incubation—1 to 4 days.—Malignant cholera. Malignant pustule. Plague. Catarrh. Dissection wound diseases.

*Short.*

b. Second Short Period—2 to 6 days.—Scarlet fever. Rosalia idiopathica. Diphtheria. Dengue. Erysipelas. Yellow fever. Pyæmia. Influenza. Pertussis. Glanders. Farcy. Grease. Croup. Puerperal fever.

*Medium.*

c. Medium Periods—5 to 8 days.—Relapsing fever. Gonorrhœa. Vaccinia. Inoculated variola.

*Long.*

d. Long Periods—10 to 15 days.—Small-pox. Vari-cella. Measles. Rotheln. Typhus. Typhoid. Mumps. Malarial fever.

*Longest.*

e. Longest Period—40 days or more.—Syphilis. Hydrophobia.

If we may accept these as the common expression of knowledge up to the present time we have still much to learn. We exclude several diseases altogether which probably have some stage of incubation, and we are obliged to grant exceptions in respect to those that admit of being more readily classed together.

The diseases of the first group are fairly steady in respect to incubation, but it may by some be raised as a question whether catarrh, either superficial or cellular, should be classed amongst the communicable diseases at all. On this point I am very interested to hear the opinion of this Society. That catarrh may be excited without communication I know, and it may be that it is always due to a general influence.

Of the diseases of the second or third group, exceptions may be adduced in which the disease may have a shorter incubation, in particular cases, than is assigned in the classification. Such exceptions must be admitted, and my own case of Scarlet fever, quoted by Murchison, shows for this disease, occasionally, a very brief incubation,—six hours at longest.

Others may question whether Rosalia idiopathica has a period of incubation at all, and whether it is not more closely allied to those affections attended with rash, which, like urticaria, are induced by improper food, than to Scarlet fever. I attended once, with Murchison, a case that terminated fatally from occurrence of bullæ in the glottis,—coming on during convalescence,—in which we never determined whether the affection, which commenced like an attack of acute urticaria, was rosolous or not. The eruption became like that of scarlet fever, with large white blotches over the surface, and in all respects yielded the form of disease which Mason Good designated rosalia parithimatica.

I would prefer, for my part, to classify these as doubtful cases, and at the same time leave them open for further study.

The diseases of the third and fourth groups will be accepted as fairly steady. Relapsing fever, as I knew it in 1847, had a longer period than five days of incubation, but by inoculation it is said to have five days.

In the last group syphilis will be accepted as having the long incubation of forty days. But hydrophobia is the most difficult disease to define. It may have a few days of incubation only. It may have months or even years.

These considerations lead up to the third question with which I opened this paper in respect to differences of opinion on periods of incubation. Do these differences depend on fault of observation, or on the circumstance that there are, in the same diseases, varying periods of incubation, the variations being under no defined rule?

My answer to this question is, that the differences of opinion so often professionally expressed, and which strike the general public with such wonder, are due rather to want of uniformity of observation than to variation of natural phenomena.

This I trace to four sets of causes—

1. That we have never yet agreed altogether as to the first sign that indicates the close of incubation.
2. That until quite lately we have not ventured to classify, so that there has been no clear grouping of diseases by the test of incubation.
3. That we have been accustomed to consider exceptional phenomena of incubation as more common and important than they really are.
4. That we have been too much accustomed to connect diseases which are most dissimilar in actual fact too closely because of certain similarities which do not really affect the question when all the facts are known.

Now that we are coming nearer to the truth we may hope to classify the exceptions, the nature of which is included under the next heading of my paper. Upon what circumstances do the exceptional periods of incubation of the communicable diseases occur, and why do they occur?

We may assume that a difference in physical property is the reason of the difference of action of the distinct poison of the defined communicable diseases. But when we are dealing with a single poison,—with the poison of scarlet fever, for instance,—the difficulty commences. We can scarcely conceive that the poison changes in character and operation; and we are, therefore, obliged to trace out its effects through the means by which it comes into operation.

In studying this difficulty we light at once upon one useful fact. We know, of a certainty, that a poison which will affect, both by inoculation and by absorption through the lungs or alimentary surface, acts according to the circumstance of introduction in distinctly different periods. In the case of small-pox, it acts one-fifth more quickly when it is inoculated than when it is absorbed through membrane. There would, therefore, probably in every case of absorption, be a difference in favour of rapidity of action, if the poison should be distributed over an injured or abraded surface, so as to inoculate such a surface in transit.

It is fair again to assume that the poison may be inhaled in a form of diffusion more ready for absorption in some cases than in others. But the great cause of difference is, I suspect, in individual susceptibility to the action of the poison, and it may be to the different influence of the same poison under different times and conditions of life. With this part of our study we have to unravel all the questions connected with the course of the communicable diseases in relation to seasons. That we should be more susceptible to the action of the poisons of the spreading diseases at those seasons of the year when there is excessive waste of bodily structure, and that we should be less susceptible to them in genial seasons when there is a balance in favour of nutrition is not a strange physiological pathological phenomenon. That we are more susceptible at the one period and less so at the other is, I suspect, more than a mere coincidence.

Here, however, I came to a point in theory which must be reserved for experimental development and exposition.

I turn now lastly, and briefly, to the practical sides of the subject in hand, and these are many. I will allude to three.

If we could arrive at definite evidence on which we could all rest, that the incubation of a disease is produced by the occurrence of a certain indication, we could account for much that seems now to be mysterious. For example, in vaccinia can it be that, trusting entirely to the local phenomena, we sometimes have an apparently good vaccination in which the disease never has incubated at all? If that be so, there is a reason why the person who seems to have been thoroughly vaccinated, should still remain susceptible to small-pox. The suggestion, though it stands alone, is all sufficient to indicate the practical importance of delivering incubation before pronouncing as to the protection afforded by some, but not all, the symptoms of a communicable affection.

The division of diseases of the communicable type into different classes or groups, according to the stage of incubation presented is, I think, a practical acquirement of the most important every day value, both in curative and preventive science. Dr. Squire has not in the least degree over estimated this part of modern knowledge. It is quite true, as he shows, that to know when to retain at home a sick person labouring under communicable disease, when to send him from home, and when to separate him from the actual or presumably unaffected, is a direction of practical skill as eminently creditable to the profession of medicine as it is useful to the public. To remove the healthy from the affected is good practice in the case of all the diseases of the first and second of the groups I have given, *i.e.*, of the quick and short incubation series. To remove in the third series may be sound practice. To remove in the fourth, or long incubation class, is less important, and may be a practice that is quite at fault and prejudicial.

Lastly, from the study of the incubation period we learn how to assign the best means of disposing of the affected during convalescence. It seems to be a true reading of natural phenomena that the diseases of short incubation have a prolonged convalescence, and remain long as sources of communication; while the diseases which show a long incubation give a quicker convalescence, and a more rapid freedom from danger as sources of communication. Here, then, is a practical lesson that cannot well be over-estimated. Keep your cases of short incubation at home: they will infect others, and be themselves injured by removal.

THE annual rates of mortality last week in the principal large towns of the United Kingdom per 1,000 of their populations were:—Hull 13, Brighton 14, Leeds 16, Portsmouth 17, Plymouth 17, Leicester 17, Bradford 17, Bristol 18, Edinburgh 18, Glasgow 20, Sheffield 20, Birmingham 20, London 20, Sunderland 21, Norwich 21, Salford 21, Newcastle-on-Tyne 22, Nottingham 22, Wolverhampton 23, Manchester 24, Liverpool 25, Oldham 25, and Dublin 25.

## AMELIE-LES-BAINS—A NEW WINTER HEALTH RESORT.

BY DANIEL H. CULLIMORE M.K.Q.C.P., F.R.C.S.,  
Physician North West London Hospital; Surgeon Indian  
Army (Retired).

AMELIE-LES-BAINS lies in a sheltered and secluded valley in the south of France, and possesses some climatic advantages to which Cannes, Hyères and even the Italian Riviera must, on account of the dreaded "mistral," ever remain strangers.

It is situated in the department of the Pyrenees Orientales, about 18 miles from Perpignan, the nearest railway station, and about the same distance from the Mediterranean in a direct line. At this distance it is possible that the influence of the land and sea breezes may exist, and it is beyond doubt that a strong wind blowing from the sea will deposit salt at a further distance inland. Canigou one of the highest of the Pyrenees rises from the northern side of the valley in which the village nestles, which being equally well surrounded by high mountains on other exposed sides is efficiently well protected from the winds.

The air is pure and bracing, and moderately exciting, as may be expected from its altitude of seven hundred feet above the sea, as well as from the fact of its being built on the rocky spur, or elevated space of the higher mountains.

The "mistral" is unknown, fogs are rare, and air dry, but not exceedingly so. Amongst forest trees pine and oak are common, while the wild lavender and other aromatic shrubs are sufficiently abundant to impart, not only a fragrant perfume to the atmosphere, but to assist, in the opinion of many competent observers, in the cure of consumption. With this opinion I am myself inclined to agree, on account of the preventive and remedial effects which in my own experience follow the inhalation of benzoin, its acids and salts in the prevention and cure of tubercular pulmonary disease. And even when powerless to cure, it is probable, that coniferous and aromatic vegetation is often an effectual preventive, and palliative, in asthma, and bronchial spasmodic disease.

A patient who recently sojourned at Amélie gives the result of her experience in the following words:—"Even in those days of wandering there is still one sheltered spot in Southern France that is not so well known as it deserves to be for a winter station, a spot so guarded from all wintry weather that on last New Year's day when many other health resorts were visited with unusual mist, frost and even snow, the invalids in this favourite nook, spent several hours out of doors, with open sunshades, listening to the singing of birds, and watching the lambs playing in the meadows by the river side. There were but ten days in November and December on which it was not possible to take exercise, and in January and after, when the south wind begins, basking in the sun becomes agreeable and pleasant to the invalid."

But this pretty village, in addition to a genial climate, aromatic, vegetation, and picturesque scenery, possesses what to the consumptive is always to be desired,—viz., sulphurous exhalation from the soil, which as I have shown "is inseparably allied with immunity from tuberculosis, and is the one connecting link that binds the semi Arctic lowlands and plains of the old world, with the torrid mountain plateaux of the new in their resistance to the encroachments of this dreaded disease. But it is especially as a sanatorium for the gouty and rheumatic, on account of its situation at some distance from the sea, and its more equable temperature that French physicians prefer Amélie to Mentone and Nice. The advantage of its hot sulphur springs which, owing to the mildness of the climate, can with safety be used for drinking and bathing is another cause of this preference. And it is in my opinion as a resort for this class of patients, together

with the bronchitic and asthmatic, rather than the consumptive, that this place will eventually become better known to Englishmen. Unless in the pre-incipient stage of phthisis, or that border land between recurrent inflammatory lung attacks, and this disease, it might without further evidence, be dangerous to recommend Amélie as a winter residence to the confirmed consumptive. The climate, though equable, is, I am afraid, too mild and too far removed in character from Quito and other places where tubercular immunity exists.

There is still one other class of sufferers—a small one perhaps, but one of which I can say with Virgil, "Hand ignari mali miseris succurrere disco," viz., the returned tropical, for whom I think at least one winter's stay at this place would prove of the greatest benefit; I refer more particularly to the Anglo-Indian or American semi-acclimatised but drooping exotic, who may have suffered from serious organic hepatic disease, or whose disordered liver dysenteric diathesis or general hyper-susceptibility to catarrhal mucus affections and internal congestions, are uncomfortably, and deleteriously affected by the east winds and damp of an English winter, or by the mistral of Nice and some other Mediterranean stations.

To many such patients the sulphur baths and the semi-inland situation of Amélie is also an advantage. As I know from personal experience that headache, mental cloudiness, furred tongue, and constipation were invariable accompaniments of a seaside sojourn.

It is not the invalid alone that will find Amélie-les-Bains a pleasant retreat. Its situation being lovely in its pastoral quietude, and sublime in its towering mountain surroundings, will inspire the poet with lofty ideas, while its proximity to Catalonia, and its mingled French and Catalan inhabitants cannot fail to be interesting to the ethnologist, and instructive to the lover of philological lore. The botanist, the geologist and the Alpine climber will find abundant occupation. Here also the busy man of the world, or the votary of fashion, leaving his cares, or his follies behind, may address himself to Nature; sitting in the mid winter and pleasant sunshine, on the pedestal of some of her wondrous and grandest operations.

The invalid should leave Amélie about the end of the second week in April, for here, as in "Sweet Auburn,"

"Smiling spring its earliest visit pays  
And parting summer's lingering bloom delays."

In this month the south wind becomes rather oppressive, and the air is close and relaxing. It is always, however, easy to move on to Prades, a small town on the north side of the mountains, where the approach of spring is about a month later than at Amélie, and which is at an earlier date exposed to the "mistral."

The accommodation at both Prades and Amélie is good. Some knowledge of French is, however, at present necessary. There is no English medical men, but as the French government have established a large military sanatorium and hospital here, and, as a railway may be expected in the immediate future, it is possible, that an energetic man who would write the place up, might do worse than take up his abode at Amélie-les-Bains.

A mile and a half from Amélie is the Catalan village Palalda, with a southern aspect, and well protected by a semi-circular mountain background. Here the air is more bracing, and the soil drier. There is, however, no accommodation, but, it only wants developing to become attractive. All who wish for further information should read "Etude Medicale sur la station Hivernale d'Amélie-les-Bains. Par le docteur Achille Bouyer. Paris and London, Baillière and Co."

MR. SENEY, of New York, has given 270,000 dollars for a general hospital to be located in the southern portion of Brooklyn. It will occupy an entire block of ground and be constructed on the cottage plan.

## CASE OF TUMOUR REMOVED BY ELASTIC LIGATURE.

By JAMES MARTIN, F.R.C.S.I.,  
Portlawn.

THE removal of tumours by the elastic ligature has not been heard much of lately, yet in country practice where cutting operations do not meet with much favour from patients who have to work, and who do not, as a rule, like to submit to much pain, it must often prove a great boon; while it performs its duties quietly without giving much cause of anxiety to the overworked doctor,—who has quite enough to harass him, without the fear of being called off nine miles to suppress a secondary hæmorrhage. The following case shows how favourably it will act in suitable cases. I would have used it at an earlier period, but it is only of late that the tumour assumed the virulent form, the outside part expanding very much during the last year.

Early in the month of January (this year 1881,) I was called to see W. N., a large powerfully made man æt 40; seven or eight years ago he showed me a small sarcomatous tumour in the inside of the ankle-joint anterior to the malleolus which I wished to remove, but he went his way and would not submit to any operation.

Again eighteen months ago, meeting him accidentally and finding that the tumour had grown very large, I proposed to remove it, and was the more urgent, that the surface had ulcerated, that there was occasionally a great deal of hæmorrhage from it, and that it was a very great inconvenience, but he refused any surgical treatment.

On the occasion of the present visit, I found that it had grown still larger, that there were several points from which hæmorrhage occurred; that he was blanched terribly in appearance, suffered from palpitation, and that a marked anæmic bruit was heard over the region of the heart. He was thoroughly alarmed, but still shrank from operation.

Seeing that something should be done, and that during the last year the enlargement had proceeded so as to leave a large neck, I took off the elastic of my eyeglass and encircled the pedicle with it very firmly.

Three days afterwards I found that the application of this ligature had stopped hæmorrhage, that the ligature had cut deeply into the structure, and that, under the use of iron and digitalis, he had improved considerably in general health.

Having obtained a piece of india-rubber string from Dublin, I removed the former ligature and again encircled it firmly. I gave him an antiseptic lotion to apply to the wound and some zinc ointment. On the sixth day I tightened the ligature again. He suffered little or no pain, and on the ninth day the pedicle holding on the tumour was so small that I gave it a snip of a scissors, and removed the mass weighing three lbs. The base cut through was  $2\frac{1}{2}$  inches in diameter; about  $\frac{1}{4}$  of an inch all round was cicatrised, and now, three weeks after removal, the sore is nearly healed and he himself, as he expresses it, is a new man relieved from a great incumbrance with very little trouble.

## A CASE OF EXTENSIVE FRACTURE OF THE SKULL FROM A FALL.

By WILLIAM BERRY, M.R.C.S.E.

Hon. Surgeon to the Royal Albert Edward Infirmary, Wigan.

THE following notes of a case of extensive fracture of the skull, from a fall, are interesting medico-legally, as well as showing that severe injury to the cranium, with fatal result, may occur from very slight violence.

I am indebted to Mr. Graham S. Coombs for the permission to publish this case, which I saw with him before death, and also assisted at the post-mortem examination.

A. B., aged about 41 years, a millworker, of temperate habits, and generally of good health, owing to a quarre

with his neighbour, went into the yard of his house, where he was followed and struck over the left eye with the closed fist, this blow caused him to fall heavily on a small iron grid about 6 by 6, which was in the yard. He lay insensible and unable to rise. Mr. Coombs was at once sent for and found symptoms of fracture of the base of the skull. I saw the patient at 11 p.m., about seven hours after the receipt of the injury, he was then lying on his back, his left eye and side of his nose were slightly discoloured, pulse 28; respiration, 12 per minute, and laboured; the pupils were widely dilated and blood and serum oozed from his right ear, he could not be roused, and occasionally he coughed up a little blood. He died next morning at 7 o'clock, fifteen hours after the fall.

*Post-mortem.*—Ten hours after death.

*External appearances.*—Rigor mortis complete, body that of a man of medium stature, fairly nourished, no marks of violence on any part of body, serous fluid trickling from right ear, left eye discoloured.

*Head.*—On removing the scalp a layer of coagulated blood was found covering the vertex. On removing the calvarium, which was very thin (about one-tenth of an inch in thickness) the superior longitudinal sinus was found ruptured, and it is probably through this, that the blood oozed through the fracture underneath the scalp. On opening the dura mater, blood was extravasated over the convolutions of the brain, from the base to the vertex, and over the right lateral half of brain, covering a space of about four by five inches.

On removing the brain, the skull was found fractured, commencing at and through the middle of the petrous portion of temporal bone on right side, and extending through the squamous portion, the parietals over the vertex as far as the edge of squamous portion of temporal on left side. The brain substance was healthy, and the lungs, heart, liver, and kidneys were all healthy.

*Remarks.*—The fracture was out of all proportion to the injury which the man had received, it is likely that it was caused by *contre coup*, the blow giving an impetus to the body in falling, and probably the vertex came against the stone edge, which surrounded the grid. The base of the skull seemed peculiarly brittle, the wing of the sphenoid being easily destroyed.

## Clinical Records.

### METROPOLITAN FREE HOSPITAL.

*Case of Stricture of the Oesophagus.*

Under the care of Dr. CHARLES R. DRYSDALE.

Reported by Mr. ABRAHAM COHEN, B.A., M.B.,  
Senior House-Surgeon.

AGNES BURNS, æt. 42, married, was admitted on the 15th January, 1881, complaining of inability to swallow solids, and great pain on making the attempt. She was not particularly thin, but stated she had been much stouter before the accident which caused the present trouble.

Enjoyed good health up to the time of her present disease. Four months ago she drank a mouthful of very hot tea, inadvertently, out of the spout of a teapot. A week after she had a sore throat, and found difficulty in swallowing solids, which has since much increased, so much so that she is now unable to partake of anything but liquids. Since the accident she complains of pain at the upper part of sternum. Family history good. On examination a stricture of the oesophagus was found on a level with the manubrium.

Jan. 19th.—Was ordered mist. pot. iod. ʒj. tr. Low diet, extra milk, Oj.; egg, j.

23rd.—Unable to swallow milk. Ordered nutrient enema. Passed a No. 14 mm. olivary French bougie through the stricture.

24th.—Able to swallow milk. Ordered extra beef-tea. Eggs, iij.; brandy, 3 ounces.

25th.—Passed No. 16 bougie through stricture.

27th.—Passed No. 23 bougie through stricture.

28th.—Passed No. 23 bougie through stricture. Able to swallow bread.

Feb. 1st.—Going on well. Bougie No. 24 passed through stricture. There appears to be a second stricture at the œsophageal end of stomach, through which No. 24 will not pass. No. 14, however, was successfully passed into stomach.

4th.—Able to partake of bread, and the liquids ordered. Passed No. 14 through lower stricture.

8th.—Passed No. 16 through lower stricture. Partook of fish.

11th.—Passed No. 18 through lower stricture.

15th.—Unable to swallow liquids. Passed No. 16. Ordered brandy, 4 ounces, which she could not swallow after passage of bougie.

18th.—Passed No. 17. Takes her food well.

22nd.—Passed No. 15 } through lower stricture.

26th.—Passed No. 16 }

March 2nd.—Passed No. 22 } through lower stricture.

4th.—Passed No. 22 }

Eats potatoes.

8th.—Passed No. 20 } through lower stricture.

11th.—Passed No. 20 }

15th.—Passed No. 22 stomach-tube through lower stricture.

18th.—Passed No. 18 stomach-tube through lower stricture.

24th.—Patient has picked up a good deal of flesh. Left voluntarily.

### CARLOW WORKHOUSE INFIRMARY.

*Curious Case of Depraved Appetite.*

By EDWARD A. RAWSON, L.R.C.S.I.,  
Medical Officer, Carlow Workhouse.

A. C., female, æt. 18, admitted April 26th, 1881. Long continued constipation, large tumour of abdomen filling entire abdominal cavity, but not connected with womb, menstruated once, three years ago, never since, very anæmic, tongue brown and furred, great prostration, paraplegia, bowels had not acted for ten days.

R. Ol. ricini, ℥ss;

Ol. crotoni, ℥j;

Fiat. haustus.

The nurse gave three drops of croton oil instead of one. Bowels acted four hours afterwards. A large bucket-ful of rags came away; amongst them were ribbons eighteen inches long, pieces of velvet, of handkerchiefs, large pieces of cloth—every kind of rag conceivable, and two portions of intestine, one about two inches in length. Two days afterwards the girl menstruated, recovered her colour, eat large quantities of natural food, and on May 3rd inst. is perfectly well, complaining she will tell her parish priest she has been starved in hospital.

## Transactions of Societies.

CLINICAL SOCIETY OF LONDON.

FRIDAY, MAY 27.

JOSEPH LISTER, F.R.S., President in the Chair.

Mr. MACCORMAC on a

CASE OF UNUNITED FRACTURE OF THE OLECRANON PROCESS, IN WHICH BONY UNION WAS OBTAINED BY SUTURES OF THE BONES.

The patient was exhibited. He was a piano-tuner, æt. 26, who, four months before coming to St. Thomas's Hospital, had fallen upon the right elbow, and sustained a fracture of the olecranon. When admitted the limb was wasted, especially the triceps; there was no power of active extension; the line of fracture ran across the base of the olecranon, the detached portion being separated by two inches, and fixed to the back of the humerus, the condyles of which could be felt in the gap, no uniting medium being perceptible. On Jan. 6th, Mr. MacCormac made a vertical incision, three inches long, exposing the fractured bone and the articulation. There was no trace of uniting material, the fractured surfa

covered with smooth fibrous tissue, and adhesions existed between the detached process and the condyles, and also between the ends of the humerus and ulna. These adhesions were dissected out, and the periosteum being reflected, a thin layer of bone was cut off with a chisel, and by means of two wire sutures through holes drilled in the bone, the surfaces were brought into close apposition. The wires were twisted and cut off, so as to project at the centre of the wound, which was afterwards closed with catgut sutures. The operation was performed antiseptically, the joint being washed out with carbolic solution (1 in 30) before closing the wound. The first dressing was made on the fifth day, when the wound was found to be united, except where the bone sutures emerged; and these were removed in twenty-one days. In forty days he left the hospital with very good active movement at the elbow-joint, and apparently firm bony union at the seat of fracture. From first to last he had no pain or inconvenience. The wound healed without a drop of pus; the temperature occasionally rose to 99·8°, but was otherwise normal throughout. He has now perfect power of active extension; the arm cannot be made absolutely straight, but he is able to follow his trade as well as before.

The PRESIDENT said he believed he had been the first to perform this operation. His patient was an engineer, who was incapacitated from work in consequence of an ununited fracture of the ulna. Having exposed the ends of the bone, and pared away the fibrous coverings of them, they were united by a single silver wire suture, which could be easily removed subsequently, while being, at the same time sufficiently strong. The case progressed without accident, and the recovered limb was as powerful as at any previous period of life. Another case occurred in his charge at King's College Hospital. In neither, however, was the fragment fixed above, nor were the broken ends so widely separated as in Mr. MacCormac's patient. Mr. Lister added that it was very gratifying to him to hear antiseptic surgery described as a matter of course by Mr. MacCormac; and he felt quite certain no one would think of incurring the risk of opening joints without antiseptic precautions.

Dr. T. COLCOTT FOX read a paper on two cases of

### CHROMIDROSIS,

In which a deep blue-black pigment exuded upon the skin of the circum-orbital regions. The paper was illustrated by several beautiful drawings, kindly lent the author by Dr. Foot, the President of the Pathological Society of Dublin. One case occurred in a girl, æt. 18, a partial deaf-mute, but otherwise intelligent and of good physique, who presented herself with Dr. Donkin's out-patients at the Westminster Hospital, for the relief of a conspicuous and symmetrical black pigmentation of the eyelids and considerable portion of the adjoining cheeks, which caused great concern to the girl and her friends. The catamenia appeared first at the age of 15, and had never since been regular in time or quantity, and since that time the girl had suffered from general malaise, severe headaches, and *very marked habitual constipation*. She was not an hysterical subject. The pigmentation was first noticed in September, 1880, on the lower lids, whence it gradually spread itself over the adjoining portions of the cheeks. Through the kindness of Mrs. Sturges and Donkin she was placed under observation in the Westminster Hospital on three occasions, and it was found that the pigmentation varied considerably in amount and intensity, though present in some degree pretty continuously. It was always less at the catamenial periods, but seemed to bear a direct relation to the very obstinate constipation, and was more intense and extended the longer the interval between the relief of the bowels. It was found on many occasions that whenever the latter were got into regular working order the pigmentation disappeared. As a proof of its genuine character Dr. Fox mentioned one night in the hospital the face was thoroughly cleansed, and the girl, who was always much annoyed by the pigmentation, was put unexpectedly and suddenly into a strange bed, in a part of the ward away from her clothes and belongings, and a nurse watched by her bedside for thirty-six hours, yet the pigmentation steadily returned. The urine was examined on several occasions for indican, and it was found that the latter seemed always to increase markedly in amount *pari passu* with the constipation and the exudation of pigment on the face. This fact and the relation of the exudation to habitual constipation are new points in connection with the disease, noticed by Dr. Fox. The examination of the pigment showed that it presented

characters in all respects similar to that hitherto recorded in other cases by Charles Robin and others. The indian-ink-looking amorphous granules were found insoluble in almost all reagents, hot or cold, but displayed a deep-blue colour when moistened with glycerine, and when dissolved in hot sulphuric acid firstly gave a beautiful purple hue and finally a bistre tint. The pigment was evidently indigenously. The second case was a girl, *æt.* 18, sent the author by Dr. Donkin, she was hysterical and phthisical, and suffered from flatulent distension and constipation. The black powdery pigment afforded similar reactions to that in the first case, but the pigmentation was slighter and more fitful in appearance. In both cases any heat, emotion, &c., which determined the blood to the face increased the pigmentation. Dr. Fox then, in consideration of the fact that these were the first cases presented to a London society, with the exception of one shown by Sir Benjamin Brodie in 1845, entered into a short *résumé* of the subject and of other recorded cases, which will be found detailed in interesting and easily accessible monographs by Drs. le Roy de Méricourt, of Brest, and Dr. Arthur Wynne Foot, of Dublin, and insisted on the reality of the affection, which he challenged anyone to disprove. To the thirty-nine cases collected by Dr. Foot he added five others, making forty-four in all, six of them being in males and thirty-eight in females, at ages ranging between fifteen and fifty-seven years, with a mean age of twenty-two. The chief points discussed in this *résumé* were the causation and the relation of the exudation to uterine troubles, general debility, and especially *constipation*; the influence of emetic, heat, &c., in increasing the pigmentation, and the sites it usually occupies; the probability of the substance being exuded in a soluble form in the *sweat* rather than sebum and its subsequent oxidation into a coloured pigment by contact with the air; the varying shades of the colour (azure, deep blue, ochreous, black) of the pigment in different patients and at different times in the same patient; the constant chemical and physical characters of the pigment which prove it to be indigenously and allied to similar products occurring occasionally in urine, pus, eczematous vesicles, milk, dropsical fluids, *fæces*, and vomit; and the arguments for and against malingering showing undoubtedly that it is a real diseased condition. Lastly, Dr. Colcott Fox gave the results of the latest researches into the production of indican in the economy, and its connection with chromidrosis.

Dr. BERNARD O'CONNOR asked if the patient had complained of continued tingling or smarting of the skin. Also whether the exuded material underwent change in colour, or was dark from the first. The advanced age (57) of one patient was a peculiar fact in connection with the affection. Was pain caused by the removal of the coloured material, as occurred in a case recorded in the "Med. Chir. Transactions," 1845? Were any constitutional effects produced by the removal? He did not question the reality of the phenomena, but regarded them as due to stearrhœa, of which there were three distinct forms, chromidrosis being of the third or non-congenital kind. Did Dr. Fox think the sebaceous glands were involved. In an early vol. of the "Guy's Hospital Reports," Drs. Addison and Gull had described five cases of a somewhat similar kind. The affection generally attacked young and pretty women, was not dangerous, but annoyed the patient by the disfigurement it produced.

Dr. CAVAFY thought the *bona fides* of the disease could not be doubted. It was attested to by the results afforded by examination of the urine, and abdominal distention favoured the view that the source of indican was, indeed, absorbed from the intestinal tract. Moreover, in chronic wasting disease, *e.g.*, phthisis and morbus Brightii, the same substance is found in the urine. It would be interesting to know if any of the patients described as secreting coloured sweat were phthisical. Variations in the lines observed could be explained in accordance with physiological and chemical principles, but he wished to be told whether the microscopic examination of the exuded material had yielded any evidence of bacteria. The corroboration afforded to the theory of a sweat centre by the emotional exacerbations was an interesting feature in the case.

Mr. JAS. STARTIN inquired if any other parts of the body than those named were seen to be stained in these cases. He had seen colouration of both axillæ in a similar case, *æt.* 40. He suggested the oxidation of the colouring matter might be due to the action of a ferment produced during the secretion of the sebaceous and sudoriparous glands.

The PRESIDENT thanked Mr. Fox for his valuable pap

er, which he said recalled to mind the *blue milk* caused by chromo-bacteria in many of his own experiments. In this, colourless cells gave rise to alterations in the surrounding fluid; a bacterial origin, however, of the appearance in Dr. Fox's cases was negatived by the facts pointing to an evidently nervous producing cause.

Dr. Fox replied that in his own case there had been very little hyperæsthesia present; it had, in some cases recorded by other observers, been nevertheless very marked. His examination of the pigment had been imperfect by reason of the minute quantity available for the purpose. No constitutional effects followed the removal of the matter, nor, in the majority of cases cited, was there any evidence of stearrhœa. In one case, however, phthisis was suspected. No bacteria were discovered in the solutions of the pigment submitted to examination. Dr. Fox did not agree with Dr. O'Connor that any connection existed between these cases and those of xanthoplasma.

Dr. W. A. STURGE and Mr. RICKMAN J. GODLEE  
ON A CASE OF STRETCHING OF THE FACIAL NERVE FOR  
TIC SPASMODIQUE.

The following is a postscript to a case recently laid before the Society:—

The patient on whom the operation was performed remained perfectly well till a month ago; then slight twitching of the orbicularis palpebrarum occurred, in connection with great mental worry; it was accompanied by some supra-orbital neuralgia. A blister was applied above the eye, and quinine was administered. The twitching has recurred twice since that time, again in connection with a mental shock, but it has now disappeared again; the patient only having some stiffness about the eye, and difficulty in opening it when exposed to a cold wind. Another patient, mentioned in the paper, on whom Mr. Godlee had stretched first one and then the other facial nerve, was also referred to; but as his case was not yet complete, it was decided to postpone a detailed account of it till next session.

Dr. DOWSE considered the report confirmed ordinary experience to the effect that cutting and stretching operations performed on nerves were never more than temporarily successful. The success which attended persistent treatment, peripherally, was such as to render unjustifiable the more serious proceedings in cases of this kind.

The PRESIDENT suggested that there was no propriety in grouping under one head operations for cutting and stretching nerves. The rapidity with which the facial nerve reproduced itself after excision was truly marvellous. It was not correct to say there had been no permanent recoveries after stretching, since Nussbaum's records of the operation contained proof to the contrary. It would, he thought, be premature to describe Mr. Godlee's case as one of failure.

Mr. GODLEE said his patient had been under the best medical treatment for five years without avail. He would defend nerve stretching on the ground that it produced no disfigurement, incurred no serious risk, and was, at any rate, partly attended with success.

Mr. GEO. LAWSON exhibited a breast which he had removed on account of long standing

#### ECZEMA OF THE NIPPLE.

In the reports of the Society for last year, after recording a case in which cancer had followed an intractable eczema of the nipple, he suggested that in cases of eczema of the nipple which have resisted for a length of time all treatment, "that the breast should be removed, in anticipation of a disease which does not then exist." The case which he had now to relate was that of a lady who suffered from eczema of the nipple which had resisted all treatment for over twelve months, and was extending. Feeling that the usual termination of such cases was diffused cancer, Mr. Lawson advised, and accordingly removed the breast. The eczema presented the usual appearances of such cases. It was a red, scaly patch, raised slightly above the level of the skin, and extending for about two inches around the nipple. The breast was afterwards examined by Dr. Thin, and he discovered cancer elements diffused throughout the breast. The preparation is now in the College of Surgeons.

The PRESIDENT referred to the serious difficulty surrounding such cases, it would be dangerous to assume cancer

in every case of eczema of the nipple, and yet the latter often preceded the grave affection. Some time ago he had been called to examine a patient with eczema of the nipple, and contented himself with ordering the application of ointments only. He had learned, at a later period, that this patient was suffering from cancer of the breast.

## Department of Lunacy.

### LUNACY LAW AMENDMENT BILL.

In the House of Commons on Thursday last Mr. Dillwyn, in moving the second reading of this Bill, said he hoped to receive from Her Majesty's Government a promise to deal with the whole subject of the Lunacy Law, but in the meantime he had brought in a short Bill to remedy some of the most striking evils in connection with them. The whole of our present system had proceeded upon wrong lines, inasmuch as it treated lunatics as a criminal class rather than as an imbecile class. It treated them with reference to their care rather than their cure, and it was to the cure that the law should be directed. The number of lunatics was rapidly increasing. By the report of the Commissioners, the number in 1859 was 36,762, in 1866 it was 53,177, and in 1880, it was 71,191. This showed the seriousness of the question. He hoped that future legislation would see the propriety of separating the curable from the incurable class. The alterations which he proposed by his Bill were directed first of all to providing a better system of supervision in the present asylums for the reception of lunatics; and secondly, to providing for the better security of the liberty of the subject than at present. He also proposed means of providing accommodation for the better class of lunatics who could afford to pay for it. This class had no resource but to go into pauper asylums which were utterly unfitted for their reception, or into private asylums. With reference to better supervision, he proposed the appointment of a paid Chairman to the Board of Commissioners, who would be accountable for the proceedings of the Board. He would allow the number of Commissioners to remain as it was, but he would give the Lord Chancellor power to appoint two additional Commissioners if he saw fit. The law regulating the reception and discharge of lunatics in private asylums was in a most unsatisfactory condition, in illustration of which he mentioned a number of cases of sane men being kept in confinement. One of these was the case of a member who sat in the last Parliament, and who, after his release was procured, sat and voted in the House for two sessions as sanely as any other member. For this class of evils his Bill proposed that it would not be lawful for any person to be received into an asylum, except by order of a Justice of the Peace, or some public authority, he did not care which, resident in the district where the lunatic lived. As a further security, it provided that the petition on which a man was to be confined should be signed by relatives within one or two degrees of relationship, or by some duly authorised solicitor. The order of the Justice of the Peace or other authority should also proceed on the certificates of two medical practitioners, one of whom should be the public officer of health of the district. He provided, in reference to the discharge of a lunatic, that the discharge should proceed upon the order of a Judge in Chambers, a Stipendiary Magistrate, or a County Court Judge, who should order two medical men to visit the lunatic and report on the case, and such judge, after communicating with the Lunacy Commissioners, might order the lunatic to be liberated within ten days. In order to provide accommodation for the paying class of lunatics, his Bill authorised the justices to raise money for that purpose by way of terminable annuities, and he had no doubt that the outlay would soon be recouped. His object was to break down the system under which it was the interest—he should not say it was often done—of the keepers of those institutions to keep high-paying patients instead of curing them. Paupers were better off. They were sent to asylums where it was the interest of the authorities to get them cured as soon as possible. He had received a letter that morning from a gentleman stating that his wife was confined in a county asylum—that he paid 9s. 8d. per week for her, but that she was treated in the matter of food and dress as a pauper. After referring to several cases of the unwillingness of medical men to release well-paying patients, he expressed his opinion

that this Bill would materially improve the law; that it would render the condition of these unfortunate people more hopeful, and that it would make more difficult the illegal and improper incarceration in asylums which had been too often practised.

Mr. Floyer said that the subject of providing asylums for all classes of lunatics was one of great importance, and it was quite distinct from the question of the management of pauper patients. To provide accommodation for all lunatics above the pauper class would require a large extension of accommodation. The hon. member said that from the profit now made in these private asylums, those who provided these establishments would be recouped for their outlay; but he (Mr. Floyer) feared that in the first instance resort would be had to the county rates. In the great majority of cases the managers of private asylums were men of high character and position, and were not capable of being influenced by the inducement of high-paying patients to keep them longer than was necessary. Such cases might occur here and there. It was for the class just above the class of paupers that he felt that some provision was most desirable. In the county asylum with which he was connected special provision was made for this class, and they were admitted on payment of 10s. a week. They were treated as regards food and dress much in the same way as actual paupers; and if this were not so they would have persons of superior class applying for admittance at the low rate of payment. He thought they were indebted to the hon. member for bringing forward this bill, and if it went into Committee he would endeavour to make it a more perfect measure.

Dr. Cameron said that the principle on which this Bill was framed had worked thoroughly well in Scotland.

Mr. Courtney in reply, observed that every person sympathised with the objects the hon. member had in view in proposing this Bill. The Bill was, however, badly drafted throughout, and it was evident its provisions would fail to carry out the intentions of the promoters. He hoped private lunatic asylums would gradually die out. With respect to the enlargement of public asylums, there was nothing at present to prevent this being done in the counties. If the hon. member was satisfied with the reception his Bill had met and would withdraw it, the Government, on the earliest opportunity, would submit a Bill, not only for the amendment of the Lunacy Laws, but for the consolidation of the whole law on the subject, an improvement which was very much required. The hon. member could hardly fail to recognise the difficulty which the Government had in transacting even important public business, and, therefore the fault did not lie with them if this matter had been so long neglected. Any Bill which the Government introduced would embrace some of the amendments proposed by the Select Committee, and some of the amendments in the hon. member's Bill would be also worthy of consideration.

Sir R. Cross said this subject was one with which he and the late Government had been most anxious to deal, and therefore, when the hon. member speaking for the Government, said he approved of all the principles contained in the Bill, he thought one of two courses would have been adopted—either to allow the Bill to be read a second time and then to refer it to a Select Committee, or to bring in a short Bill with the points upon which there was mutual agreement. He quite agreed with the hon. member that to consolidate the whole law on the subject would be an admirable thing to do. In fact, it was so admirable, he was afraid it would not be done because such an undertaking, while not of the first importance, would be one of magnitude, as they would find that any measure with this object would eventually be thrust out and indefinitely postponed in the pressure of other legislation.

Mr. Dillwyn said he must go to a division to ascertain the opinion of the House on the principles of his Bill. If the Bill was badly drafted, which he denied, the Solicitor-General had acted conjointly with himself in drafting it.

Sir W. Harcourt said that after the appeal made by the right hon. gentleman, the Government would not go to a division. As to the proposal that the Government should introduce a short bill on the subject, he was sorry to say the Home Office was full of short Bills and it was absolutely impossible to find five minutes to introduce one. He could not consent to the Bill going to a Select Committee, because the House was already overburdened with Committees, nor could he give any promise that the Bill would pass this Session; but if his hon. friend liked to take the second reading of the

Bill, and his chance of passing it when amended, the Government would offer no objection.

The Bill was then read a second time.

ANALYTICAL REPORTS ON THE PRINCIPAL BOTTLED WATERS.

By CHARLES C. R. TICHBORNE, LL.D., F.C.S., F.I.C.  
President of the Pharmaceutical Society of Ireland, Lecturer  
on Chemistry, Carmichael School of Medicine, &c.

WITH

NOTES ON THEIR THERAPEUTICAL USES.

By PROSSER JAMES, M.D., M.R.C.P.Lond.,  
Lecturer on Materia Medica and Therapeutics at the London  
Hospital, Physician to the Hospital for Diseases of the  
Throat, &c.

(Continued from page 446.)

### THERAPEUTICS OF THE ALKALINE WATERS.

FEW remedies are more interesting than the alkalies, and they have always been the subject of speculation; for simple, as at first sight, some of their effects appear, there are secondary actions about which there is grave doubt. At times they have been so generally lauded as to be constantly prescribed, and then there has come a reaction in which it has been maintained that they are apt to prove injurious. This being the case with regard to the pharmaceutical preparations of the alkalies, we need not be surprised that the popularity of alkaline spas sometimes seems to wax and wane. Still, these springs have from early times maintained a high position, and increase of our therapeutical knowledge seems to extend rather than restrict the indications for their use. It is obvious that alkalies have a great role to play in practical therapeutics, but this need not blind us to the possibility of their abuse.

Alkaline waters, and for that matter all the potent mineral waters, like other important remedial agents, should be prescribed with care, and patients should not take them except under professional advice. For a like reason medical men should make themselves familiar with the qualities and value of these waters, as well as with those articles of our materia medica which enter into their composition. In any form alkaline remedies are useful and effectual whenever they are judiciously prescribed, and certainly many mineral waters offer us an agreeable method of employing them.

M. Mialhe, whose researches on this subject extend over many years, has arrived at the conclusion that the alkaline bicarbonates really belong to the class of aliments quite as much as iron, phosphate of lime, chloride of sodium, and other inorganic bodies. As like other salts, the alkaline bicarbonates form a necessary part of the animal economy, as their presence is necessary in a sufficient quantity to maintain certain chemical reactions, he thinks the proportion present in the body cannot vary without giving rise to grave disorder, but that an increase

would be much less deleterious than a decrease in their quantity, because an excess is easily removed by the secretions, while there is no way of compensating for an unnatural diminution. This, however, does not satisfy M. Mialhe, who maintains that, in proper doses, the alkaline bicarbonates cannot be injurious, and even in doses far exceeding the usage of our therapeutists, he holds that they are quite inoffensive, and may even be beneficial. He holds, too, and physiological chemistry—of which he is an acknowledged leader—seems scarcely able to dispute the doctrine, that the physical nature of our tissues and vessels presents an insurmountable obstacle to any increase or decrease of the proportion of salts in the blood. Whenever a liquid is introduced into the system containing more of any salt than the blood requires, the excess of that salt escapes by the bowels. Such is the general statement which, although accepted in so many instances, is frequently not admitted in reference to the alkalies, or at least not present to the prescriber's mind, and which M. Mialhe apparently holds as universally true. According to him we cannot alkaline ourselves to any extent we may propose, though we may do so within certain limits, and this degree of alkalisation is, of course, all that is required in therapeutics if this be so.

But how about the alkaline cachexia of which so much has been written? If these views be founded on fact, such a condition could never arise as a consequence of the ingestion of alkaline remedies. Accordingly, we are not surprised to find that the author of these views joins MM. Durand-Fardel, Willemin, Boucomont, Petit, and other observers in scepticism as to these ill effects. At Vichy Durand-Fardel has never seen the so-called alkaline cachexia; yet there, if anywhere, unless, indeed, the explanation lie in the kind of alkali, which we shall discuss further on, we might expect it to be occasionally met with. Willemin, so far from admitting the waters of Vichy to be debilitating, claims for them tonic properties under certain conditions. Boucomont, Pupier, and Petit, hold a similar doctrine. In support of this view it has been recorded that as much as 50, 100, 120 grammes of alkaline bicarbonates have been taken per day without doing any injury. We suppose, however, that our readers will regard such experiments as on a par with those made as to the number of tumblers of water that can be swallowed in twenty-four hours. It is well known that the enthusiastic hydropathists have drunk excessive quantities, and they are to be congratulated on the activity of their skin and kidneys at the time they made such a strain on their secretory apparatus.

Although the existence of this alkaline cachexia is denied it is admitted that improperly administered, alkalies may give rise to serious disorders, especially in cases of anæmia, of great debility, or where there is any excess of alkalinity in the system. May this admission serve to convey the differences of opinion that have obtained? All acknow-

ledge that properly administered in suitable cases, alkalies would at least be very unlikely to do mischief, while improperly given in unsuitable cases, they may cause serious disease. At the same time it should be observed, that many of the cases of so-called cachexia have appeared after the administration of large quantities of alkalies for a considerable period during an acute attack of rheumatism. It is difficult to maintain that the case was not suitable, as others exactly similar did so well under the same treatment. It may be thought that in the system of one patient there was an inability to get rid of excess, or that another had some unknown condition affecting the issue, or that the disease had varied; but these are only conjectures, and it is not easy to understand why the same doses, of the same drug, at the like intervals, apparently under like circumstances, should often prove so beneficial and occasionally so disastrous. Here the differences in the effects of the several alkalies ought not to be overlooked. Foreign writers, in speaking of the alkaline treatment, are apt to forget this point. They never omit to cite the mineral waters of Vichy, and the opinions of the residents at that celebrated spa. But now we would add, that soda being the alkali of Vichy water, it may be that the conclusions are drawn from observations, not necessarily applicable to the alkaline treatment of acute rheumatism, which is carried out in most places with potash, and, as we have said, it is after this disease that injury has been most frequently noticed. There can be no doubt that potash, as a rule, is less easily tolerated than soda. Potash lowers the blood-pressure and the temperature. It seems to possess a direct action on the heart, causing it to beat with less power. The potash salts are some of them very potent cardiac depressors; indeed, they may be called cardiac poisons. They notably depress all the powers of life, but this may be partially due to some influence on the spinal centre. At any rate, it will be seen that potash and soda differ much in their effects on the system, and although it is to be preferred in certain cases, it is always more likely to do mischief. It is, however, only right to remember the case of the illustrious chemist Therand, who fell into a state of grave cachexia after dosing himself with bicarbonate of soda to the extent of thirty grammes per diem. Few of our readers will be likely to recommend the pushing of the drug to this extent, and we suppose those who deny the danger of alkaline cachexia, will say that such an abuse of the remedy was not rational.

*(To be continued.)*

FROM diseases of the zymotic class in the large towns last week, measles showed the largest proportional fatality in Bristol and Sheffield; and scarlet fever in Wolverhampton, Sunderland, London, and Oldham. The 26 deaths from diphtheria included 9 in London, 7 in Portsmouth, 6 in Glasgow, and 2 in Bristol. Small-pox caused 114 more deaths in London and its outer ring of suburban districts, and one in Salford, while no fatal case of this disease was registered in any of the other large towns.

“SALUS POPULI SUPREMA LEX.

WEDNESDAY, JUNE 1, 1881.

### INCUBATION OF THE COMMUNICABLE DISEASES.

THE theory of incubation is a natural outcome of that of specific poisons. If without a desire for exactitude either expression be used, it furnishes us with a convenient explanation of phenomena presented by a large class of diseases; but if we desire to assign to each a distinct and definite significance, then it is that difficulties insuperable present themselves. Referring to the paper by Dr. Richardson in another column it is evident that from this point of view the talented author addressed himself to the task in hand; hence, at its very outset, the queries as to the precise application of the term “incubation,” and as to the amount of absolute knowledge regarding the thing, the application of the correct term for which is as yet uncertain. Surely this is dealing with the indefinite and abstract. It is perfectly true that “the period between the introduction of the poisonous particle and the period of manifestation of action is the period of incubation”—in so far as popular language is concerned. But in such a case the term incubation is inapplicable in its ordinary sense, inasmuch as the particle itself is not known to produce from within itself other particles or organisms; but rather, its own pernicious qualities to

extend throughout the system and affect the several functions of its recipient. Then again, the term is hardly applicable in reference to diseases which arise from particular combination of circumstances, but without the intervention of any specific poison, and yet which having occurred are capable of transmission from person to person. Of such diseases typhus and dysentery of camps and transports of former days, erysipelas and pyæmia in hospitals, and cholera in times of epidemics are instances, and others could be mentioned. With regard to cholera the author observes that the disease first attacks its subject by way of a chill, also that there is "a physiological reason for accepting chill or rigor as the indication that the poisonous particle has taken effect." But in times of epidemics in India cholera often attacks with violent purging or vomiting, or both, chill, and decreased temperature occurring, not before, but after the violence of the attack has induced collapse. How, also, with regard to these cases, and they are by no means of unfrequent occurrence in some parts of India, where *chill*, occurring in the ordinary course of intermittent fever, is at one time succeeded by the hot stage of that disease, at another by cholera, and on yet another occasion by phenomena so precisely simulating the one and the other, that the result alone really furnishes the diagnosis. In such cases difficulty would be considerable if, as laid down by the author, we "should take the first rigor as the first sign of the disease, and should accept the intervening period between the introduction of the cause and the development of the rigor as the true period of incubation." As already indicated, there occur diseases in regard to which the origin is due to the general conditions in which their subject is placed rather than to "the introduction" from without of a specific poison, and yet which became communicable. The author very correctly observes that these are diseases regarding which a question may arise whether there be a period of incubation at all; if such affections are due to certain kinds of food, as urticaria and some others. Like everything else that the author writes, the paper here referred to is most valuable, as are the practical lessons with which he closes it, namely, that to remove the healthy from the affected, is good practice in the case of communicable disease, the *incubating* period of which is quick and short; to remove those in which incubation is five to eight days in duration may be sound practice, but that in cases of long incubation, removal is less important, and may be prejudicial.

#### THE PROGRESS OF THE IRISH INFECTIOUS DISEASES BILL.

SINCE we congratulated ourselves last week on the defeat of the Notification of Infectious Diseases (Ireland) Bill affairs have taken a turn which calls for the immediate and energetic action of the profession in Ireland to prevent the Bill being made law. The following is the report of what took place on the 23rd ult., when the measure was counted out:—

On the order of the day for going into Committee on this Bill, Dr. Lyons appealed to the hon. member who had charge of the measure to postpone its consideration. It was opposed to the wishes of certain of the most impor-

tant of the learned corporations of Ireland. He had been requested by these authorities to offer opposition to the measure.—Mr. M. Brookes hoped the bill would be allowed to go on. The opportunity which private members had of making progress with their measures was very small; and this, though a private member's Bill, was a very important one. It had been received with unanimity by the public bodies and the private citizens of Dublin.—Mr. Meldon objected to proceeding with the Bill at the hour of 1.30 A.M. The hon. member for Dublin (Mr. M. Brookes) had said that the public bodies and the private citizens of Dublin were in favour of the Bill, but there was anything but unanimity on this subject in Dublin. The medical profession of the city were divided upon it, also the private citizens.—Mr. R. Fowler would suggest that the House should go into Committee, and that progress should at once be reported.—Mr. Callan said the Bill had been a long time on the paper, and there were several amendments. The Solicitor-General for Ireland appeared to be quite ready to proceed with his amendments, and the hon. member for Dublin (Mr. Brookes) was present. The hon. member opposite (Dr. Lyons) had not placed any amendments on the paper so far. If he wished to amend the Bill, he should propose his amendments, and not throw the measure over beyond the Whitsuntide recess.—The Solicitor-General for Ireland said the Bill had been under the consideration of the Chief Secretary, and he (the Solicitor-General for Ireland), with the right hon. gentleman's concurrence, had placed certain amendments on the paper. These amendments he had submitted to those who had charge of the Bill, so that any desirable modification might be suggested. He was perfectly ready to proceed with his amendments, but, of course, he had not charge of the Bill. He thought the hon. member for Carlow would do well to take only a formal stage now. The bill was one of great importance, its object being not a private, but a public one. There were several portions of Ireland where the measure was badly wanted.—The House was counted out at 1.35 A.M.

Since these proceedings took place the Bill has been again placed on the notice paper, and its committee stage will be taken on the first opportunity. The amendments entrusted by the Irish Medical Association to Dr. Lyons, M.P., have not been placed by him on the notice paper, and consequently the proposition of that association that the householder shall be the person to notify infective disease will not, under present circumstances, be moved, but instead a motion will be made by Dr. Lyons to refer the Bill to a select committee; and, if this motion fail, the measure will be debated in committee of the whole house, and a variety of amendments discussed, none of which fully meet the views of the medical profession.

It will be seen that there is imminent danger of this unnecessary, unremunerative, and irksome duty being forced upon the profession throughout the whole of Ireland unless an immediate and energetic protest against the Bill be made without a moment's delay, and we earnestly advise each one of our readers to guard himself and his brethren against this monstrous imposition by writing letters, without the delay of a post, to the county and borough members who represent him, and to all other M.P.s whom he can influence, begging of them to oppose the further progress of the Bill, and, if it goes into committee, to vote against any or every proposal which compels the attendant physician to notify the case of infectious disease in writing. To exercise such influence upon his representative is the legitimate right of every constituent. It will take only a few minutes to do so, and both public and personal reasons require that it shall be done at once, and universally.

Dr. Lyons' proposal that the Bill should be sent to a select committee we deprecate in the strongest terms, except as a means of delaying and defeating the measure. To send a Bill which deals with Irish doctors before a committee of English legislators, who will be well plied with the argument that the notification of infective disease is effectively performed by the doctors in seventeen English and Scotch towns is to doom the profession in Ireland to inevitable defeat. What can a dozen English and Scotch members be expected to know or care about the differences between sanitary law, dispensary practice, and the customs of our profession in Ireland and in England; and what evidence will it be possible for Irish doctors to place before such a committee which may convince them that the law suitable for the one country is unfit for the other. The clearest proof that our anticipations of the verdict of a select committee would probably be realised is the fact that those who desire to force the duty of notification upon the Irish physician are the persons who have induced Dr. Lyons to send the Bill before the committee, and from the further fact that the notification party, while they soothed the hostility of the profession by promising full inquiry and full justice, took no means to obtain that inquiry so long as it appeared possible to pass the Bill, in the teeth of the profession without it. We therefore advise our readers to inform the members to whom they write that they greatly distrust the reference of the matter to a select committee, but, nevertheless, prefer that this course should be adopted rather than that the Bill should be permitted to go into committee of the whole house, where there would be still less chance of the voice of the profession being heard.

#### THE LUNACY BILL.

THE persistency with which Mr. Dillwyn has clung to his Lunacy Bill, was recognised on Wednesday last by the House of Commons consenting to hear it read a second time. Even the energetic author of the measure, however, will hardly be likely to regard his triumph as any reasonable indication of a general acceptance of his views. Every earnest advocate of reform will welcome the opportunity afforded by the occurrence, of exposing the evils attaching to the administration of the law as it stands at present, but for a reason that will hardly commend itself to the shallow critics who accept reports in place of prosecuting inquiry concerning that they so readily condemn. These, like the open-mouthed rustic at a country fair, absorb all, and understand nothing. They take for representations of actual facts the distorted pictures presented by sensational dramatists and novelists; and, brimming over with righteous, but ridiculous, indignation, they demand the immediate redress of their imaginary grievances. We do not pretend that Mr. Dillwyn is one of these deluded persons; we feel sure that the proposer of a Parliamentary measure has carefully and conscientiously investigated the whole of the facts connected with the subject of his Bill. We do not doubt that he is convinced of the desirability of introducing changes into the lunacy law of the present; but we do venture to think that he would not so precipitately demand the changes he has embodied in words, had he an

intimate personal experience of the working of these laws—to be obtained only by careful watching of their effects for a lengthened period. Reform is called for, and urgently needed; but not in the way Mr. Dillwyn and his followers explain. If, in place of dealing hidden—but none the less certain—blows against the existence of private asylums, these advocates of change would for a time direct their energies to the real weakness of the lunacy administration of this country, they might quickly find subject matter for much instructive reflection. In place of private asylums, let them consider the defects and shortcomings of public institutions in which the insane poor of this country are incarcerated. Let them do only a little towards removing the depressing prison-like surroundings of these "homes of the mad," and the blessings of a thousand recovered patients will be the reward for their well-doing. When the highest authority on lunacy in all America can say of our private asylums that they are incomparably superior to any in the world, as places of recovery; and when he pays the highest possible tribute to their excellence by a determination to model American institutions after them, surely Mr. Dillwyn and the whole band of reformers may take heart of grace awhile, and bend themselves to the task of making the State prisons of mental disease more like the centres of private treatment and cure. Then will they be performing a great work—a work of imperative necessity, and that will yield illimitable returns in the way of good results.

As it stands at present, the Lunacy Bill is a useless and purposeless measure. It can tend to do little more than make yet more complicated existing regulations, and the fresh provisions it contains, when examined and carefully considered, are remarkable chiefly for their utter inutility. What point, for instance, is there in the requirement that a certificate of committal shall bear the signature of a medical officer of health, and that, too, of the district in which the chosen asylum is situated? The special characters which testify to superior qualifications in mental medicine possessed by health officers, are not yet apparent to uneducated eyes, and this will possibly account for our utter inability to follow the reason for Mr. Dillwyn's suggestion. Of course Mr. Dillwyn's inquiries may have led to the discovery of an occult connection between sanitation and madness, but it is one which has, up to the present, successfully escaped the notice of all other observers. Similarly, too, we do not see the strength of Mr. Dillwyn's suggestion that discharge shall follow the order of a judge in chambers, a stipendiary magistrate, or a county court judge, a report on the case being first presented by two medical men. It is not stated whether either of these latter is to be possessed of the qualification in sanitary science, so that we may assume, though it requires a sanitarian to diagnose insanity, mental soundness may be apparent to a mere physician. Also the addition of the judicial functionary's signature is to be looked on, we presume, as a sort of set off and ornamental recompense for the publicity the proposed alteration will bring upon afflicted persons who have the misfortune to recover their reason. No other ground can be assigned for the signature, since the patient is not to be interviewed by the signatory, who apparently will act

throughout the proceedings like those upright stakes placed by the South Sea Islanders as spectators and approvers of their performances on great occasions. There can be no objection to the introduction of such changes in the law as would ensure the impossibility of committal by partial or improper persons; not because this is done to any serious extent, or even with frequency, but because it would tend to disabuse the uninformed of their chief impression respecting asylums. It is pitiable to read, even in generally well-informed lay papers, the nonsense written in connection with this subject; and any discussion or other means taken to enlighten the ignorance abounding on all hands concerning it, must be productive of advantage.

Mr. Dillwyn's Bill stands no chance of passing into law this session. He will be acting wisely if he follows the suggestions made to him, to remodel and readjust the clauses of his measure. As it is, no body of sensible men could accept it; as it might be made, we could see our way to giving it a certain amount of support. But ere this can be, the alterations must be many and considerable. Mr. Dillwyn should bear in mind that the weakness of popular declamation against the lunacy laws lies in the utter ignorance of those who so freely condemn them, and that true reform is based on accurate knowledge. With these thoughts before him, he may be able to draft a trustworthy and valuable measure.

#### THE MONT DORE CURE.

THE treatment of those diseases associated with inflammation of the respiratory passages has always been a subject of interest, and very often of deep concern, to the physician. The success which has attended the treatment of "winter cough" in the establishments devoted to its cure on the Continent, has also, from time to time, been the subject of consideration; and in the recent few months an attempt to introduce the plan followed at these institutions into our own country, has been energetically followed and carried to, at any rate, a successful commencement. The "Mont Dore" system of treatment, as followed in the sanatorium of that town in Auvergne, and consisting of a combination of baths, mineral waters, and special exercises, has been particularly introduced to the notice of English practitioners by Dr. Horace Dobell, who conceived the idea of establishing an institution after the same model at Bournemouth, having selected that place, as he tells us, "as the most suitable—if not the only completely suitable—place for establishing the Mont Dore arrangements in this country." His idea was favourably received by the resident medical men, and a company was subsequently formed to carry it out. On Wednesday last the King of Sweden laid the foundation stone of the new building, and we may expect that ere very long a fair trial of the advantages and powers of "Mont Dore" will be made.

It is undoubtedly a fact that a vast number of cases of winter cough, and the slightly grave naso-pulmonary affections are greatly susceptible of rapid cure if submitted to sufficiently early and appropriate treatment. Likewise we must admit that there is at present no place in this country which combines the advantages for which

"Mont Dore" is famous, and which serve to render it so especially valuable as a resort for patients affected in this way. Consequently there is ample ground for supposing that as a mere mercantile scheme the new institution should command success. There seems a danger, however, lest in the desire to extract the utmost good possible from the natural advantages possessed by Bournemouth, these may be altogether destroyed, an event which would at once and for ever ruin the prospects of the Mont Dore as a curative establishment, and reduce Bournemouth itself to a third or fourth rate, and by no means attractive, seaside resort. This danger will appeal to every resident in Bournemouth; but it struck us with the greater force, perhaps, from our regarding the spot with the eyes of one unaccustomed to its features. We refer, of course, to the woods surrounding the town behind. That Bournemouth owes its best characteristics to their presence is an undeniable fact; and equally true is it that if they are destroyed during the next few years with the same rapidity the growth of buildings shows them to be undergoing demolition at the present, then Bournemouth will degenerate to a disagreeable and uninhabitable, bleak, coast side town. As it is, however, it is a delightful spot; and if it is permitted to retain its present attractions, the Mont Dore institution can hardly fail to be a source of benefit to innumerable invalids. As we have said, there is ample need of such a place, and it will be readily appreciated. The prospectus of the scheme details its chief features, but the best account of the Mont Dore treatment, and of the effects it produces, is to be found in a work just published on the subject by Dr. Horace Dobell, to whom is primarily due the merit of introducing it into this country.

It is highly gratifying to note the interest taken in the undertaking by the distinguished visitors who have found Bournemouth so health-restorative. The Queen of Sweden has received a great amount of benefit from her stay there; and both by consenting to perform the ceremony of laying the first stone of the Mont Dore, and by his expressions of grateful appreciation, the King of Sweden testified his recognition of the advantages his family has received from the place. In every way the directors of the Mont Dore are to be congratulated on the success already attending their efforts. We cannot do other than heartily wish them a continuance of it.

#### Notes on Current Topics.

##### Royal Medical Benevolent College.

THE annual general meeting of the Royal Medical Benevolent College was held at the London offices on Thursday last. The chief business of the meeting was that of receiving the report of the scrutineers, and the result of the balloting for pensioners and foundation scholars. This being the second election that has taken place since the alteration of the rules with regard to the mode of election was brought about, the issue, on the whole, may be looked upon as satisfactory. Both pensioners, and nine out of twelve candidates for foundation

scholarships, recommended by the Committee of Selection, were elected by the governors and subscribers, so that the house list was nearly carried in its entirety, in the face of considerable efforts that were made by the friends of candidates, put up for the first time. Only one of the latter, however, was elected, and this was certainly a strong case. The boy was one of a family of nine, and the father had, for several years, been a subscriber to the College. It has been made a subject of discussion, that so very few of the friends of candidates seem to contribute towards its support. On running over the present list we find that of the fourteen candidates for pensionerships, four only subscribed, and of the forty candidates for scholarships, five only of the parents had ever subscribed to the College. In most other class charities it is made an absolute rule that the parents of applicants shall have been regular subscribers for a time, otherwise candidates are ineligible. We are much inclined to think that the Royal Medical Benevolent College should adopt a rule of the kind. This would have the effect of reducing the list of candidates. We are of opinion that the Committee of Selection acted wisely on this occasion in their attempt to clear off candidates whose claims had been urged year after year upon the governors, for the fourth, fifth and sixth time; "the relative claims" of all of whom, under the present rule, certainly rendered them not only eligible, but in most instances, the claims were "most urgent." It is a matter for regret that the boy who stood No. 9 on the list, was again unsuccessful. He is one of a family of six, left in a state of destitution, and having, at some expense, stood three elections, his name is now finally removed, he becomes *ineligible from age*. The claims of No. 32 might well have been postponed a year to make way for the poor boy Albury. The Report deals with other matters of interest to the governors. The educational qualities of the College are modestly alluded to, but it is agreeable to notice that the boys are fairly up to the mark, and able to pass, without additional help, the Cambridge, and other University matriculation examinations, and that a full share of honours and scholarships were secured by them, a proof that the standard of proficiency is well maintained by the pupils of the College. The health of the boys, and that of the pensioners, has received a considerable amount of attention. The requirements of modern sanitary science seemed to render it absolutely necessary to overhaul and re-arrange the drainage, and secure a better supply of water than that obtained from the town. At some cost a well was sunk, and a spring struck, which has turned out to be all that can be desired. It is somewhat disappointing to find that the balance by some few hundreds of pounds is on the wrong side, and that, although exercising every care and economy in management, the treasurer is unable to pay his way, and keep the College out of debt.

#### Metropolitan Hospital Sunday Fund.

THE Council of the Hospital Sunday Fund met at the Mansion House on Monday, under the presidency of the Right Hon. W. McArthur, M.P., Lord Mayor. The first business on the agenda paper was that of sanctioning the

general arrangements, as printing, advertising, &c., prior to the ensuing Metropolitan Hospital Sunday. A report likewise was received and came up for adoption from the General Purposes Committee, on the question of admitting Surgical Aid and kindred societies for supplying the poor with surgical appliances to participate in the fund. It will be in the recollection of our readers that at the last annual meeting a resolution was passed to the effect that the Council should be asked to draw up a scheme whereby these societies might be permitted to share in the Hospital Sunday Fund. Steps were thereupon taken to request a conference, and deputations asked to attend at the Mansion House to discuss the question at issue between the Council and the Surgical Aid Societies. Two only of the six societies thought proper to respond to the Lord Mayor's invitation. After a long and careful consideration the following resolution was unanimously come to by the Council of the Hospital Sunday Fund:—"That having heard the statements of the deputations, and finding the societies represented still consider themselves compelled to encourage the system of obtaining letters (or money equivalent to letters) of the value of the surgical appliance from patients, the Council are more than ever confirmed in opinion that the system adopted by the Hospital Sunday Fund for providing surgical appliances, as at present in operation, is the right one, and in every way preferable, and sufficient to meet the wants of necessitous cases. The Council is therefore not prepared to recommend any scheme which would interfere with what is at present working with so much advantage to the poor and necessitous." We may conclude from the absence of the Surgical Aid Society that its managing committee are quite unable to justify its cruel mode of compelling poor cripples to beg over London for letters or money; and, therefore, the more prudent course would be to abstain from attempting to justify its mode of action before the Council of the Hospital Sunday Fund. The Lord Mayor and Sheriffs will, as heretofore, attend in state at the St. Paul's Cathedral and Westminster Abbey services.

#### The Royal Commission.

THE Royal Commission appointed to receive evidence on the working of the Medical Acts, has unfortunately commenced its business in a way that will seriously interfere with the success it could be expected to obtain. It has decided to hold its sittings in secret, thereby incurring that which it should be the first object to avert—viz, suspicion and distrust. By refusing to admit the representatives of the press to the *séances* of the Commission, those responsible for the order have been guilty of a grave error, and one that will not improbably go far to rob the decisions of the Commission of its chief weight, not only with the medical profession, but also with the public, whose interest is intimately associated with the proceedings of the Committee. There is something eminently distasteful to the present mind of the nation, in the pretence of mystery; there is absolutely nothing in the nature of the labours before the Commission to justify its assuming the cloak of mystery; there is, moreover, every reason for demanding that the world shall be kept *au courant* with what is done as it is done,

that there may be no danger of important subjects being inadequately or improperly discussed. If the report of the Committee is to have any value, or any considerable influence in determining the direction of future reforms, it must be one in accord with the opinion of a majority; and this can be assured only by the majority's being cognisant of the steps by which it is reached. Thus only can the Commission hope for assistance and support. Even it, is not too strong to be without the need of it; and even it, cannot afford to have its judgments unfavourably criticised, as it assuredly will if it arrive at them in opposition to the growing and irresistible demand for great and radical improvement. We have the highest respect for the members of the Committee, and on this account as well we warn them, ere it is too late, to avert the storm. The public, professional and non-professional alike, is too deeply interested in the question at issue, to submit without a protest to the compelled anxiety of a lengthened expectation.

#### Transplantation of Bone.

THE reproduction of bone from grafts has been again and again tried, but until lately no one has been able to record a successful attempt in this direction. As was the case with skin grafts, difficulties arose, and had to be vanquished one by one; but at length a veritable case of new growth from grafts has been recorded, the successful operator being Dr. McEwen, of Glasgow. The subject of the experiment was a child, four years old, admitted into the Glasgow Infirmary in 1878 for necrosis of the right humerus, the shaft of the bone having separated, at that time, from the epiphysis. Operation was resorted to, and the affected bone removed, with the result that fifteen months later there was no bony connection between the condyles and head of the femur. The absence of the shaft and periosteum made it a matter for conjecture as to the proper situation for a new shaft; but guiding his operation by anatomical principles, Dr. McEwen made a sulcus where he considered the bone should be, and in this groove deposited grafts of fresh bone chipped from pieces removed for curing curved tibiae in other patients. The fragments united together, and adhered above and below to the head and condyles of the humerus remaining in situ; and, ultimately, a solid shaft of bone was formed, no more than half-an-inch shorter than that on the opposite side of the body. It is necessary to remark that anti-septic precautions were adopted, and are declared by Dr. McEwen to be essential to the success of the operation. As in the case of skin grafts, the pieces of bone require to be very small, thus admitting of more perfect nutrition than would otherwise follow; but the history of this first case tends to prove that there is nothing to prevent this method of repair from being extensively resorted to in the future. That it opens up a prospect of far reaching benefits is at once plain; and, probably, each one will at once suggest the renewal of bone destroyed by syphilitic ulceration by this means.

#### The Late Dr. Barnard Davis.

THE well-known collector of the incomparable series of crania, known as the "Davis's" collection, and now the property of the Royal College of Surgeons, died recently

at Hanley in Staffordshire. J. Barnard Davis, the most indefatigable English anthropologist of the present age, was eighty years old, and had spent nearly his whole life in the town where he passed his last moments. In 1823 he took out the licence of the Apothecaries' Society, and twenty years later became M.R.C.S. Eng., graduating as M.D., St. Andrew's, in 1862. His studies were directed during his later life to the question of craniology, and in conjunction with Dr. Thurnam, he published in 1856 the "Crania Britannica," with which his name will be always associated. Throughout his business life as a country practitioner Dr. Davis was always alert to secure any chance specimens of skulls that were to be obtained, and thus it was he gradually accumulated a collection of which the Hunterian Museum can now boast the possession. "A long life and a useful one" is the worthy record of the deceased *savant's* existence. Without any startling events to work its calm progress, he yet achieved a great and valuable work, and leaves behind him memorials that will perpetuate his recollection so long as science is the study of man.

#### Memorial of Harvey.

MR. ALBERT BRUCE JOY'S statue for the Harvey Tercentenary Memorial is, says *Nature*, now cast in bronze, and will probably be soon sent to Folkestone, the native place of the discoverer of the circulation of the blood, where a suitable site has been provided for it on that well-known promenade the Læes. In modelling his successful statue, Mr. Joy has closely followed the portrait of Harvey by Janssen, preserved in the Royal College of Physicians. Mr. Joy has also produced a reduction of the bust of Harvey.

#### The International Medical and Sanitary Exhibition.

IN consequence of the excessive number of applicants for space at the forthcoming exhibition her Majesty's Commissioners have placed the western Picture Gallery at South Kensington at the disposal of the committee, and the Royal Horticultural Society have given up the whole of their arcades for the purposes of the exhibition. These extra facilities will assure to all exhibitors good positions, and the committee will also be able to receive further applications for space up to the end of the present week. The number of exhibitors who have already paid for space far exceeds in importance those of any previous exhibition of a similar kind. The exhibits not only include the leading industries connected with medicine and architecture in this country, but they include important contributions from France, Germany, Austria, Italy, Switzerland, Russia, Belgium, Holland, Norway, India, and the United States. The number of exhibitors has been so great that the final allotment of space has been delayed in consequence. The plan of the exhibition buildings has now been completed, and the exhibitors will know the positions they are to occupy by the 1st of June. The exhibition opens on the 16th of July. Mr. Mark Judge, the secretary, will supply all information at the Parkes' Museum, University College.

### Society for Relief of Widows and Orphans of Medical Men.

THE annual general meeting of this valuable charity was held a few days since in the rooms of the Royal Medical and Chirurgical Society, the President, Sir Geo. Burrows, Bart., in the chair. The report for 1880 was read by the secretary, from which it appeared that a sum of £2,942 had been distributed during the past year among 60 widows, 15 orphans, and 3 recipients of the Copeland Fund. The expenses of the year were £177 11s. 3d. The total receipts available for payments of grants and expenses had been £3,132 17s. 5d.; the grants and expenses had been £2,119 12s. 3d., leaving only a balance of £13 5s. 2d. at the end of the year. The funded property of the Society had not been increased. During the year one widow had died, and two had become entitled to grants, two orphans had become ineligible for further grants, and three had been elected. Eight members had died, and six had resigned, and only three new members had been elected—leaving a total of 375 members on the books at the close of the year. The following office-bearers were elected for the ensuing year: Drs. Semple, Self, Augustus Brown, and Cumberbatch, Mr. Spencer Watson and Mr. Vasey to be members of the council *vice* the six senior members who retire. A vote of thanks was unanimously passed to the editors of the medical journals; and it was resolved that the court of directors should be requested to consider the desirability of sending a circular to all medical men residing within the area of the society's operations.

### Otology at the British Medical Association Meeting.

THE ensuing meeting of the British Medical Association at Ryde will doubtless be somewhat overshadowed by the glories of the International Medical Congress, which immediately precedes it. The number of sections is therefore limited. Besides the four sections of medicine, surgery, obstetric medicine, and public medicine, there is, however, to be one sub-section, *viz.*, of otology. Dr. Urban Pritchard, of King's College, is to be chairman, and Messrs. Douglas Hemming, of Bournemouth, and Cresswell Baber, of Brighton, hon. secretaries. It is intended to devote the two first days of the meeting to discussions on the two following subjects:—1. The relation of diseases of the nasal passages and naso-pharynx to aural affections. 2. The treatment of acute suppurative inflammation of the middle ear, with especial reference to the perforation of the mastoid. Each of these subjects is to be reported on by a gentleman who has given special attention to it, and it is intended, if possible, to circulate the conclusions of these reports, which will form the basis of discussion, among those who have signified their intention of being present, some time before the meeting takes place.

In consequence of the continued increase in the number of cases of small-pox, and the want of hospital accommodation for isolating cases of this disease, the Asylums Board has received the authority of the Admiralty to select a suitable ship from among those laid up at Chatham, for conversion into a temporary hospital ship.

### Cocculus Indicus in Epilepsy.

IN the *Mich. Med. News*, Dr. H. M. Hurd states that he has tried *cocculus indicus* in cases of confirmed epilepsy with good results, the number and severity of the attacks being almost invariably reduced and the intellectual activity improved, rather than diminished as it so often is by the use of bromides. It appears to answer best where the patient is otherwise in good health and the convulsive attacks are attended with mania. In the *Virginia Med. Monthly*, Drs. A. U. Wiseman and W. S. Crump record cases of epilepsy treated with *gelsemium*, in which the fits ceased soon after the treatment, and did not recur again for several months.

### Burglary in a Registrar's Office.

ON Monday week the office of Dr. Boyd, registrar of births, deaths, and marriages for New Ross, co. Wexford, was broken open, and an iron safe containing the registration books stolen away. In the morning the safe was found in a marsh by the river side outside the town, broken open, and the books and papers scattered about, the burglars being sadly disappointed at not finding any money or valuables.

### Incision in Purulent Pericarditis.

AN extraordinary and interesting case is recorded in the *Berliner Klin. Wochenschrift*, No. 5, 1881: A boy, ten years of age, suffered from empyema and purulent pericarditis. The pleura was accordingly tapped, and thirty-eight ounces of serous effusion were withdrawn. The pericardium was tapped, and about four ounces of pus taken out. The patient's condition did not much improve; there was very considerable and increasing dyspnoea, with lividity, and some œdema of the feet and legs; sleep was much broken, and the general condition very low. Under the circumstances, it was determined to incise the pericardium, as the physical signs pointed pretty conclusively to a further accumulation of fluid within it. The operation was carried out under the strictest antiseptic precautions. An incision, about three centimetres long, was made between the fourth and fifth ribs, close to the left margin of the sternum, and each layer separately divided until the pericardium was reached. An opening was then made into it, through which a considerable quantity of pus escaped; two drainage tubes were put in, and the wound dressed after Lister's method. The patient was, very shortly after the operation, able to lie on his back, and felt much relieved by it. It was not however, until at least two hours later that the pulse became appreciable. On the day following, the temperature stood at 101° Fahr., but it then came down to normal and remained so. At the end of eight weeks the pericardial wound, which had been gradually closing, was cicatrised. There were no further pericardial troubles. But the signs of the pleuritic effusion pointed to a fresh collection in this cavity, while there was still fever after removing thirty-five ounces of fluid; as the general condition, therefore, was not relieved, a free incision was made into the chest, and another fifty ounces were removed. Improvement now set in, and at the end of six weeks the wound had closed, and the patient was sent out of the hospital cured.

The author draws the following conclusions from his case:

1. The case teaches that purulent pericarditis, just as empyema, may at times run its course without giving rise to fever or œdema of the tissue, so that the nature of the exudation can only be decided after an exploratory puncture. 2. We must not abstain from removing the exudation on account of any supposed myocarditic changes. 3. In cases of considerable pericardial effusions, change of position may not influence the line of dulness; but this fact must not always be interpreted in favour of dilatation of the heart.

### The Relation of Brain Structure to Intelligence.

THERE is plainly to be noticed a growing doubt among the most competent biologists as to there being any fixed relation between brain structure and mental function. That pet theory of a few years back is not now tenable. There is a *tertium quid* in the evolution and action of intelligence which we cannot yet put our finger on. One example in point may be mentioned, from a recent lecture of Prof. Calderwood, of Glasgow. Speaking of insects, he quoted Sir John Lubbock with reference to their position in the order of development. Sir John said that, though the anthropoid apes ranked next to man in bodily structure, ants claimed that place in the scale of intelligence. Once he had watched an ant working, and it worked from six in the morning to ten at night without intermission, carrying one hundred and eighty-seven larvæ to its nest. Professor Calderwood said that it became apparent that anatomical structure was not in itself an adequate guide in determining comparative importance in the scale of organic existence, and that even comparative brain structure could not be taken as a sole test of the measure of intelligence. The whole order of ants presented quite exceptional difficulties for the theory of evolution, and also for the theory of intelligence, which seeks to account for it by complexity of brain structure.

### Rights of Public Teachers to the Material of their Lectures.

A CASE of much general interest has just been decided by the Supreme Court of the State of New York. The facts briefly are as follows:—Dr. Darling, professor of anatomy in the University of New York, has for years been accustomed to have an assistant, before the hour of his lecture, place upon the blackboard certain tables and diagrams, which he had found useful in the teaching of anatomy. This work was done for some time by Leo T. Meyer, a medical student, now a graduate. Dr. A. L. Ranney is Prof. Darling's assistant in teaching anatomy. In 1879, Dr. Darling and Dr. Ranney sold to the Putnams, medical publishers, the right to publish the substance of Dr. Darling's lectures, under the name of "The Essentials of Anatomy." About the same time that this was issued, Meyer published a work called "Meyer's Guide to the Study of Anatomy." This was avowedly taken from Dr. Darling's lectures, and its claim for patronage rested solely on Dr. Darling's reputation as a teacher of anatomy. The Putnams applied for an injunction to prevent Meyer from selling his work. Recently, the Courts have granted this injunction, so that hereafter Meyer can only sell his book to the medical students of the University, and on the

grounds of said college building. This permission was given on the ground that Dr. Darling had given to Meyer permission to print and sell to Darling's classes the synopsis of his lectures.

The Court held that "mere permission to print, without permission to publish, does not divest the author of his property rights."

"Lectures and plays are not, by their public delivery or performance in the presence of all who chose to attend, so dedicated to the public that they can be printed and published without the author's permission. It does not give to the hearer any title to the manuscript or a copy of it, or the right to use a copy. In the case of Abernethy, it was held by the Courts that while students might take full notes of the lectures, yet they could only use them for their own information, and not publish them in a medical journal without the author's permission. In short, they could not sell a lecture which they had not bought for selling.

The decisions thus given in this case are of much importance, in that they establish: 1st, the right of lecturers to retain full property in material which has been publicly delivered in the form of lectures; and 2nd, the value of a verbal permission "to print" as affecting a formal contract "to publish."

### The Policy of the Irish College of Physicians in Reference to Medical Coroners.

FROM the following letter it will be observed that Dr. Lyons, M.D., has felt himself obliged to refuse to present to Parliament the petition adopted by his own college praying *inter alia*, that medical practitioners should be no longer permitted to hold coronerships.

SIR,—I have felt it my duty to the profession of which I have the honour to be a member, to decline to present to Parliament a petition which prays that any "reform of coroners' law which may receive the support of Her Majesty's Government should contain the following essential provision:" "2. That every coroner should be either a barrister-at-law or on the roll of solicitors." To this prayer of the petition of the King and Queens College of Physicians in Ireland, I beg leave very respectfully but firmly to demur; and I believe it to involve such a vital principle, as affecting the public rights of the profession, that I have begged the college to relieve me from the embarrassment of presenting to the House of Commons a petition from the prayer of which I so fundamentally differ. It has been all through my life my aim to secure for the profession of medicine that full recognition of right and equality with all other callings in the State, to which I believe it to be so justly entitled by its learning, its services to humanity, and the high character of its individual members. I am convinced that the well-educated physician is as fully competent and as well entitled to fill any office in the State to which he may be called, as any other member of the community; and I shall never consent, directly or indirectly, to the imposition of a disability or disqualification on a member of the profession, such as that now sought to be entailed upon him.

I will venture to affirm, after careful search, that no such condition as that referred to has ever been sought to be placed on the office of coroner, from the earliest statute which I can find on the subject—that of 3rd Edward I, of the year 1275, entitled "What Sort of Men shall be Coroners," and the 11th and 12th Edward I, (1283-1284)—statutes drawn with all the wisdom and care which marked the legislation of that great sovereign

and which, as has been very properly observed, in regard to all public questions, and, I would add, inclusive of land-legislation, would do credit to the times and reign of Victoria.

That the College to which I have the honour to belong, and which has so justly earned a high place in the history of medical corporations, should seek to impose this disability on its own alumni, whom it has ever sought to raise to the highest standard of medical and general culture, is a circumstance of astonishment and regret. Amongst its own Fellows will be reckoned the founders of peerages; and it has recently delighted to honour the war-services of Dr. Reynolds, V.C., at Rorke's Drift, to speak of no other instances. Of the many distinguished medical men who have filled administrative posts with singular ability and high credit to the State, I will only mention Dr. Sandwith, Sir Samuel Rowe, etc.

It is because I feel that to close even one door of the great avenues to public service would be to give evil example and to yield a vital principle, that I contest the action of the College on this occasion. I purposely avoid discussing the nature or functions of the office, on which much may be said to support the opposite view—that taken by the College; and I desire to enter my protest on the broadest ground, and to record my opinion that the well-educated physician is fitted for any position in life to which his fortune calls him. I have the fullest confidence that the profession will sustain me in this view with no uncertain voice.—Yours faithfully,

R. D. LYONS, M.P., F.K. & Q.C.P.I.

17 St. James' Place, London, May 25th, 1881.

WE understand that drugs and chemicals were the first subjects taken up by the French Treaty Commissioners at their meeting yesterday.

In the principal large foreign cities, the mortality, according to the most recent weekly return, was in—Calcutta 46, Bombay 33, Madras 37; Paris 28; Geneva, 24; Brussels 24; Amsterdam 26, Rotterdam 19; The Hague 24; Copenhagen 19, Stockholm 30, Christiana 16; St. Petersburg 64; Berlin 27, Hamburg 27, Dresden 22, Breslau 31, Munich 35; Vienna 32; Buda-Pesth 35; Rome 24; Venice 26; Alexandria 33; New York 35, Brooklyn, 22, Philadelphia, 23, Baltimore, 21 per 1,000 of the various population.

## Scotland.

(FROM OUR NORTHERN CORRESPONDENT.)

**THE COMBE LECTURES.**—On May 24 the fourth of a series of Combe lectures were delivered by Dr. Andrew Wilson, F.R.S.E., in the Training College, Edinburgh. There was a large attendance. Dr. Wilson began his lecture by describing the haunch bones, along with a lower limb, and in referring to the heel of man remarked that while humanity owed much to its hands, it likewise depended largely on its heels, which were a most efficient fulcrum, and assisted greatly in the easy maintenance of an erect position. Proceeding to describe the functions which the muscular tissue, or flesh of animals performed, he said that muscle enabled us to execute ordinary movements, and assisted in food digestion through movements of the alimentary system. It was also a means for the expression of the emotions, for speech, and for the circulation of the blood, the heart being a hollow muscle. The structure of muscle, and its division into voluntary and involuntary

muscle, was next described, and Dr. Wilson concluded by referring to peculiar forms of movement occurring in living beings, and known as ciliary and amoeboid movements. The latter form of motion, he said, was seen in the white corpuscles of the blood, the lecturer remarking that it was curious to find in the human organism myriads of particles of protoplasm, which to all intents and purposes had as free and independent powers of movement as the animalcules of a pool.

**SMALL-POX IN SCOTLAND.**—The Board of Supervision have issued to local authorities a circular calling attention to the great danger at present existing of the disease of small-pox being widely spread or becoming epidemic in Scotland. It states that in London small-pox is widely prevalent, and one instance is known to the Board in which the disease has been very recently imported thence to Scotland. The stream of foreign emigrants (mostly unvaccinated) passing through Scotland on their way to America presents another source of danger, and cases of small-pox have actually occurred among these emigrants in the course of their journey through Scotland. The Board therefore think it expedient to direct the special and immediate attention of local authorities to the powers and duties entrusted to them by the Public Health Act, by means of which the disease may be mitigated and checked when it occurs in Scotland. The circular then proceeds in detail to point out the four precautionary and preventive measures to which every local authority should at once direct their attention, viz., vaccination and re-vaccination, removal of nuisances, notice of cases, hospitals and isolation of the sick, machinery for the carrying out of which the Board provides.

**SMALL-POX AT GLASGOW.**—Of late several deaths from small-pox have been registered in Glasgow. Two of the cases were Swedish emigrants on their way to America. Precautions have been adopted with a view to detection, isolation, and treatment of infectious diseases among emigrants.

**DEATH-RATE OF GLASGOW.**—The deaths in Glasgow for the week ending with Saturday, the 21st ult., were at the rate of 24 per 1,000 per annum, as compared with 26 in the previous week, and 25, 23, and 24 in the corresponding weeks of 1880, 1879, and 1878.

**HEALTH OF EDINBURGH.**—The death-rate of Edinburgh for the week ending with Saturday, the 21st ult., was 19 per 1,000, the total deaths being 78. No deaths from fever, diphtheria, measles, or small-pox was reported, and only six from scarlatina and whooping-cough.

**ANTI-VIVISECTION CONFERENCE.**—A conference of ladies and gentlemen opposed to the practice of vivisection was held on the 21st ult., in one of the rooms of the Bible Society, Edinburgh, under the chairmanship of General Grant. There was a small attendance, the majority of those present being ladies. The customary motions were proposed and adopted. Dr. Doig, Bathgate, took part in the proceedings.

**THE LATE PROFESSOR SANDERS.**—A meeting of the medical profession was held last week, in the hall of the Royal College of Physicians, to take into consideration the propriety of erecting a monument to the memory of the late Professor Sanders. It was proposed by Professor MacLagan, and seconded by Professor Balfour—"That this meeting, having regard to the affectionate esteem in which the memory of the late Dr. Sanders is held by his numerous friends, is of opinion that expression should be given to it by the erection of a permanent memorial." It was also proposed by Dr. Joseph Bell, and seconded by Dr. Underhill—"That a committee be appointed to consider in what manner this object may be carried out, and to raise the necessary funds for doing so."

Dr. Batty Tuke and Dr. Blair Cunninghame were appointed joint and honorary treasurers and secretaries.

**THE COUNTESS OF ABERDEEN AND THE MATERNITY HOSPITAL, EDINBURGH.**—On Friday last, the Countess of Aberdeen visited the Royal Maternity and Simpson Memorial Hospital, and was received and conducted through the hospital by Dr. Keller, acting physician on duty; Professor Simpson, Dr. Angus Macdonald, Mr. Turnbull Smith, C.A., the secretary; and Mrs. Mather, the matron. Her ladyship minutely inspected the hospital, and expressed her great satisfaction with the arrangements and with the general appearance of the house. Before leaving, Lady Aberdeen gave each of the patients a little book, accompanied with a kindly word, and expressed to the secretary her willingness to become the patroness of the institution.

**THE ROYAL COLLEGE OF SURGEONS, EDINBURGH.**—At the last meeting of the College Professor Spence and Dr. P. H. Watson were elected to attend the meetings of the Royal Commission on Medical Education. Dr. Joseph Bell, the secretary of the College, will accompany the deputation as prompter, in case his services may be required.

**THE MEDICAL OFFICER OF HEALTH FOR ABERDEEN.**—The appointment to this office will not be made till the third Monday in June.

**THE ABERDEEN MILK EPIDEMIC.**—The report of the Board of Supervision inspectors is not yet published, but it is believed that it will award great praise to the skill and energy displayed by Dr. Beveridge, the chairman of the Health Committee, in suppressing the further spread of the epidemic, which at one time threatened most serious results.

#### THE ANNUAL REPORT OF THE IRISH COLLEGE OF SURGEONS.

THE annual meeting of the College to receive the Report of Council will take place on Saturday next. The Report states that the Council have held during the year forty-five meetings, which indicates constancy in active work since the date of their election, this number of meetings being greatly in excess of the number usually held.

During the year 14 candidates were admitted to the fellowship, 103 received the letters testimonial, and 10 the diploma in midwifery; 94 candidates for the junior examinations, and 40 for the final, were rejected. Three hundred and thirty-five candidates presented themselves for the preliminary examination, of whom 88 were rejected; 111 gentlemen received the diploma in dental surgery. The entire number on the lists of the College amounts to 350 fellows, 3,156 licentiates in surgery, and 270 licentiates in dental surgery.

The College began its year with a balance of £358 in hand, and ended with £267 in bank, the total outlay being £6,158. This, however, included £742 paid to the builder of the museums on completion of his work, and £488 to the same builder for miscellaneous building work for some years past. The dental examinations brought in an income of nearly £1,500, out of which the College had to pay for expenses and for refunds to rejected candidates £611. Passing by the section with reference to the library and museum, the Report gives the proceedings of the Council with reference to a variety of matters of interest which space does not permit us to recapitulate, the chief of which is the new scheme of education and examination. The document is, in our opinion, a very insufficient and unsatisfactory account of the stewardship of the Council. Presented at a date when most of the matters contained in it have ceased to have much interest, and when all action upon these matters by the Fellows is too late, the Report would be of little use to the constituency even if it gave them full information. But this it does not do, for it offers to the Fellows nothing but bare resolutions, the circumstances under which these resolutions were adopted being omitted, and the amendments and votes thereon being left out. Amongst the other remarkable omissions in this Report is the absence of any allusion whatever to the reso-

lution adopted by the College at its meeting this time last year, requesting the Council to send to the Fellows at least once each quarter a *précis* of its proceedings. By a unanimous vote the Fellows preferred the request that they should be kept informed as to the doings of the Council, and not only has that request not been complied with, but the recommendation has been entirely ignored in the annual report. We have reason to know that the resolution of the College was acted upon, and that a *précis* of the first half-year's work of the Council was prepared, but it was not sent to the Fellows for reasons which, no doubt, the President will be prepared to state. We, however, think that the Fellows who appoint the Council have an indisputable right to know how the persons so appointed discharge their duty, and ought to be afforded the opportunity to judge how far such persons are worthy of their votes; and we rather think that if divisions in Council were taken *coram publico*, the constituency might receive unexpected enlightenment as to the opinions and acts of their representatives. At any rate, the complete disregard of the recommendation of the College on this subject needs explanation, and we shall be interested to hear what excuse can be offered for treating it with silent indifference.

#### THE ANNUAL MEETING OF THE IRISH MEDICAL ASSOCIATION AND THE MEDICAL BENEVOLENT FUND SOCIETY OF IRELAND.

THESE meetings will be held on Monday next, June 6th, at the Royal College of Surgeons in Ireland. The business of the day will be inaugurated by a breakfast, given at the Shelburne Hotel by the President of the College, Dr. McClintock, to the members of the Association. The meetings will be especially interesting this year. The Report of the Council of the Association not only gives a most creditable *résumé* of work done for the interest of the profession in the past year, but deals with subjects of extreme interest to Poor-law medical officers, and gives to the members information of the projects which the Council has in hand for the coming year. The important and difficult problem of Poor-law medical superannuation is at length within the scope of practical politics—a matured scheme for a Widows and Orphans Fund will be submitted—the acts of the Council in reference to the notification of infectious disease will probably be discussed, and the probable legislation on coroners and on Irish Lunacy Law will be considered.

This is a programme worthy of consideration, and we hope to see a full meeting present to express the opinions of the members on these points, and to encourage the Executive of the Association by showing an interest in their work. The dinner in the evening is always a professional gala, and it will, we understand, be this year more numerous attended than usual. Invitations have been issued to several Peers, Members of Parliament, and heads of departments.

#### THE IRISH COLLEGE OF PHYSICIANS AND THE NOTIFICATION OF DISEASES BILL.

THE Registrar of the College of Physicians in Ireland has officially addressed to the Dublin papers a note that "Dr. Lyons's statement that, in opposing the commitment of the Infectious Diseases Bill, he represented the medical profession in Dublin is incorrect," and that the "College of Physicians are in favour of the principle of the Bill." We have already pointed out the perfect truth of Dr. Lyons's statement for which he had the warrant of a vote of two to one of the medical practitioners in Dublin, and we need not go beyond this to justify the City member in his statement.

But we are curious to know how the Registrar can justify the assertion that his College is "in favour of the principle

of the Bill." The only impression which any one can derive from the letter is, that the College endorses the proposal of Mr. Gray that the physician should be compelled, under penalty, to give a written certificate of each case of infective disease. This proposal, and nothing less, is "the principle" of the Bill, and it is not straightforward to represent the College as approving of "the principle of the Bill," because it holds (as every one does) that notification by some one is desirable, when, in fact, the College has declared itself directly hostile to the proposal of Mr. Gray to which we have referred. That the Irish College of Physicians joins heartily in the general condemnation of this Bill is beyond doubt, for we have before us their official "observations" and their amended copy of the Bill itself. We quote from the former document the following passage: "In July, 1880, the President and Fellows adopted a resolution expressing their readiness to advance legislation for that purpose, *provided that the onus of notifying be placed solely upon the owner or occupier of the house* (or other responsible person) in which infectious disease may occur. The College still hold the same view, as they believe it would be injudicious to impose the responsibility of notifying upon the medical attendant."

The College goes on to express the hope that the Bill "to which there are strong objections" may not become law until a Select Committee shall "have reported" thereon, and it proceeds as follows:—

"The College believing that to impose upon the medical attendant the duty of notifying directly to the sanitary authority as to the infective nature of the illness of his patient might tend to a breach of confidential relations which should exist between the physician and his patient. They consider that the legal responsibility of notifying to the sanitary authority should entirely devolve upon the head of the family, or owner or occupier of the house in which infectious disease occurs, and that the duty of the physician shall cease when he shall hand to the head of the house a certificate as to the nature of the illness."

If this be what the Registrar describes as approval of the principle of the Bill, we think that Mr. Gray will not thank the College much for its very limited approbation, and we further think that the profession will agree that the statement made in the official letter of the Registrar is inexplicably at variance with the real fact.

Finally, we venture to inquire why these "observations," dated April, 1881, have not seen the light until Monday, the 23rd of May. Every one knew that the Bill was going to a second reading, yet the opinion of the College was withheld, and it was not until after the date at which the Bill was to have gone through Committee that the Fellows were presented with the text of this condemnatory manifesto of the College.

## Correspondence.

### THE NOTIFICATION OF INFECTIOUS DISEASES AND THE IRISH MEDICAL ASSOCIATION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The attention of the Committee of Council of the Irish Medical Association having been directed to an article in the *Medical Press and Circular* of the 25th May, in which the action of the Irish Medical Association with regard to the Notification of Infectious Diseases Bill is referred to, the Committee of Council desire it to be distinctly understood that the article in question was not written or published with their knowledge or authority.

By order of the Council

of the Irish Medical Association.

8 Dawson Street, Dublin,  
May 30, 1881.

[If the article referred to in the foregoing note were susceptible of being interpreted as an authoritative or even a distant semi-official utterance of the Irish Medical Association we should, in the interest of that body, approve of the foregoing repudiation, for it would be obviously inexpedient and dangerous that such an organisation should be held liable for editorial writings over which it has no

control. After careful perusal of the article in question we cannot find that anything which it contains justifies the Executive of the Association in disclaiming words which were never in the remotest degree attributed to them, but which, on the contrary, bear the obvious impress of being unofficial and journalistic. As, however, those who desire to victimise the profession in hope of a visionary gain to sanitation, might seek to make capital against the Irish Medical Association by connecting it with the editorial which seems to be so objectionable to them, we will deprive them of the chance of doing so by publishing the above letter, and declaring, editorially, that no person unconnected with the *Medical Press* is responsible directly or indirectly for any part of the article. While we recognize the propriety of a medico-political association preserving carefully the independence and self-responsibility of its own acts, we must be as cautious with reference to our own freedom of speech, and we, therefore, avail ourselves of this opportunity to say that our editorial policy has not been, and will not be, shaped in any way on the pattern of the policy of the Irish Medical Association. It has been a pleasure to us to find ourselves almost always in accord with the purposes aimed at by that body, and the means adopted to attain its objects, but we may to-morrow find ourselves "in the opposition lobby," and if so we certainly shall not ask leave of the Association (as the Association is not expected to ask ours) to advocate what we think best for the profession. As, by the foregoing letter and these observations it has been made quite clear that the Association and ourselves are totally irresponsible the one for the other, we hope we shall not again be favoured with unnecessary disclaimers on the subject. We can, perhaps, better than the Association, afford to disregard the ire of Mr. Gray and the numerically insignificant section of the profession who seek to burthen medical men with the obnoxious duty of notifying infectious disease, and we, therefore, need not hesitate to speak much more emphatically and decisively on the subject than any association can wisely do, and we shall certainly continue to use our own language and policy, even at the risk of being "repudiated."—Ed. M. P. & C.]

### CLINICAL RECOGNITION OF IRISH UNION HOSPITALS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I will thank you to publish the enclosed list of Irish union hospital physicians, who have authorised me to append their signatures to a memorial to the Senate of the Royal University, praying for the recognition of one year's clinical attendance at such hospitals.

The General Medical Council, and some of the more enlightened colleges, have indeed recommended students to spend one year at such hospitals, but this permissive legislation has notoriously broken down, and with its breakdown vanished the chance of that practical training which the scattered students who, under other circumstances, would have attended them, would have obtained at them, and which certainly can now only be obtained by the mass of those attending regular clinical hospitals, who have too often to struggle to peer over one another's heads in order to obtain even a dim vista of the distant patients. This list is merely the first batch of names received. I urge the rest of my hospital brethren to send in their names as soon as possible. Two deputations will also be organised, one to wait on the Senate, and the other to interview the medical members of it. The justice of our claims, and the earnestness with which my proposal has been taken up, leave no doubt as to the ultimate result. The Senate has already, by the recognition of midwifery attendance at our hospitals, so committed itself that if other grounds were wanting it would be logically obliged to fully acknowledge our just claims. I am rejoiced that my hospital brethren have taken the matter up so warmly, and are so fully alive to the great advantages which they, students, the public, patients, medical science, and all parties concerned, would derive from turning to clinical account the 111,000 patients that are annually treated in the great network of the union hospitals of this kingdom.

There will be a private conference of union hospital physicians at the Hibernian Hotel, Dublin, on Monday, June 6th. The conference will be held within an hour after the early trains arrive, say about half-past twelve o'clock. I would urge as many as possible to attend, and request those who

intend doing so, to communicate with me beforehand. Those who may desire it can afterwards attend the Medical Association.

I am, Sir, yours, &c.

THOMAS LAFFAN.

Cashel, May 25th.

Drs. Thomas Woods (Parsonstown), R. Macanley (Ballina), Michael Macnamara (Corofin), R. Bradshaw (Carrick-on-Shannon), E. Rawson (Carlow), John Adrien (Drogheda), R. Barry (Limerick), R. W. Ronayne (Youghal), Abraham Kidd (Ballymena), George Peirce (Newcastle), Wm. Carleton (Delvin), Andrew Nolan (Gort), Hans Fleming (Omagh), J. W. Killen (Larne), Andrew Spearing (Antrim), Richard Murphy (Carrick), E. Fitzgerald (Mallow), R. O'Ryan (Ballieborough), John Roche (Fermoy), H. O'Farrell (Boyle), G. O'Farrell (Boyle), P. J. Nicolls (Navan), C. J. Payne (Clifden), J. M. Nichols (Dublin), J. G. Adamson (Lurgan), N. Mahon (Ballinrobe), R. O'Reilly (Lismore), P. J. Cremen (Cork), T. Fleming (Croom), A. McConnell (Belfast), C. Coote (Kilrush), Brice Smyth (Belfast), John J. Dnigenan (Edenderry), G. M. Hearn (Bawnboy), Edward Maguire (Cork), G. W. Adrien (Balrothery), Luke Shanley (Athlone), A. B. Veey (Magherafelt), Wm. O'Neil (Mitchelstown), G. K. Given (Gortin), T. Scully (Clonmel), David J. Browne (Londonderry), T. H. Moorhead (Coothead), Charles McDonnell (Glin), M. Spotswood (Cahirveen), P. W. Cullinan (Ennis), Robert Thompson (Uringford), Michael Shanley (Strokestown), G. M. O'Connor (Ballycastle), R. E. Parke (Newtownards), J. Miles (Dingle), D. O'Brien (Ennistymon), Thomas Hayes (Rathkeale), Henry Webb (Dingle), E. Hadden (Clonakilty), J. Dowling (Tipperary), G. W. Daly (Dunshauglin), Thomas Laffan, (Cashel), M. D. O'Connell (Kilmallock), M. O'Connor (Limerick), Fitzjohn Irwin (Kilkeel), Joseph G. Burne (Dublin, South), James Kelly (Ballinrobe), P. L. O'Neil (Athy), James C. Holland (Dunbarvan), J. R. Minnitt (Nenagh), R. D. Kenny (Dublin, North), J. Hartigan (Croom), and B. Madigan (Kilrush).

London Hospital Medical School.—The following is a list of the prizes awarded at the recent scholarship examinations:—*Clinical Medicine*: Mr. J. A. Williams; Mr. Harris and Mr. Adkins (honorary certificates). *Clinical Surgery*—Mr. J. A. Williams; Mr. Russell (honorary certificate). *Anatomy Scholarship*—Mr. Alden; Mr. J. Thomas and Mr. Langton (honorary certificates). *Anatomy, Physiology, and Chemistry Scholarship*—Mr. F. H. Taylor; Mr. Gordon (honorary certificate). *Out-Patient Dressers' Prizes*.—Mr. Nicholson, £15; Mr. F. H. Taylor, £15; Mr. Blaxland, £10. *Duckworth Nelson Prizes*.—Mr. J. A. Williams; Mr. Russell (honorary certificate).

## NOTICES TO CORRESPONDENTS.

DR. H. (Edinburgh).—Yes, we noticed the "crib" unacknowledged from our column; but it has occurred so frequently that we have given up directing attention to the practice.

DR. PIRSON.—We intend devoting a series of articles to the subject referred to in your letter in the course of a week or two; evidence is being collected in order to treat the subject exhaustively.

MR. RIVINGTON is thanked; his request shall receive due attention.

C. J. H.—We have not had a suitable case under our notice lately in which to test the remedy; it has not escaped our notice.

DR. J. MURRAY LINDSAY.—It has been passed on to the proper channel, and will doubtless receive early attention.

MR. G. T. A. F.—We are at all times glad to receive local medical news of interest, and friendly hints from our readers; but dictatorial advice as to the views we should adopt, in the style of our correspondent's letter, amounts to impertinence. When he has provided himself with "A Few Rules of Medical Etiquette," and learned some of those elementary lessons which usually guide gentlemen in their conduct towards each other, we shall be glad to hear from him again.

MR. W. JOHNSTON (Bathgate) will receive a private note.

MR. STEPHEN ALFORD'S paper "On the Practical Treatment of Dipomania" is marked for insertion in our next. The slips for private distribution shall be sent him as desired.

### THE EVILS OF TIGHT LACING.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

I WAS glad to read your article on this subject last week. It is one which I have always taken great interest; and upon my opinion being recently asked by a mother with several daughters as to the best of stays, corsets, tight lacing, &c., from 14 to 20 years of age, my reply was, that all such practices were most injurious, tending to the utter destruction of the muscles of the spine, with its distortion and curvature of the ribs, and oft-times destruction of the self-supporting character of the spinal column. It has at all times been my

practice, when consulted about the health of young females, to severely censure the previous medical advisers of vain and ignorant mothers, for not warning them of the mischief they were so thoughtlessly inflicting upon their daughters—the mothers of the rising generation. The only remedy I can suggest would be to instruct not mothers, but young men in search of wives, in the nature and degree of this horrible deformity—a *wasp waist* produced by tight lacing, and to give them some idea of the natural figure of a well-formed young female; and if it were once discovered that such physical deformity was really diminishing the chances of matrimony, tight lacing would soon go out of fashion.

Yours respectfully,  
M.D.

ROYAL MEDICAL BENEVOLENT FUND OF IRELAND.—Notice is given in our advertising columns of the thirty-ninth annual meeting of this Society to be held on Monday next, to which all interested are cordially invited.

MR. GRIFFITH.—You cannot do better than read up for the fellowship from the books you mention.

### THE BATTLE OF THE HOFFS.

HITHERTO it has been customary that editors should be held responsible for what ever appears in the columns under their especial charge; but our burdens were made to appear heavier when a day or two since we received a solicitor's letter requesting us "to insert in your next issue a suitable apology, the wording of which we feel sure we may leave to your good feeling." This demand was made in consequence of the appearance in our last issue on page xiii. of an advertisement headed "Hoff's Malt Extract." This well-known extract of malt has been for years advertised in this and other leading medical journals; but there is a split among the Hoff's, and the lawyers are to be treated to a share of the prey in consequence. It seems to our non-legal minds that this request for an apology should have been addressed to Mr. Coleman of Glasgow, or Mr. Leopold Hoff of London, they alone being responsible for the advertisement. However, that is other's business than ours, and no apology is needed from us.

We may, however, give the following particulars which is the limit of our knowledge of the matter: Some ten years since a Mr. Newman inserted an advertisement in this Journal of "Hoff's Extract of Malt" for the first time, and has continued to insert and to pay for similar announcements as Mr. Johann Hoff's Sole Agent for the United Kingdom, to the present time. During the past few months a Mr. Leopold Hoff opened an office in London, advertising himself as the only person entitled to use the name of Hoff, and that no other extract of malt but that bearing his signature was genuine. Thereupon Mr. Newman, the original and sole agent of Mr. Johann Hoff, the manufacturer of the original article, issued "caution" advertisements, and at the same time placed the matter in legal hands. It now appears that Mr. Leopold Hoff is a son of the brother of Mr. Johann Hoff. No one can dispute his right to the name of Hoff, but whether he is justified in cautioning the profession and the public against an unauthorised use of Hoff's name by Mr. Newman, who is still the recognised agent of Mr. Johann Hoff, is another matter—one, in fact, upon which we must not pronounce pending the decision of a legal tribunal. Meanwhile, that portion of the profession which has been accustomed to prescribe the original Hoff's Malt Extract will form their own judgment of the rival claims.

EPIDEMIOLOGICAL SOCIETY.—This evening (Wednesday), at 8, Annual General Meeting.—Election of Office Bearers. Annual Report of the Council.—Mr. George Fleming, "On the transmissibility of Diphtheria from Animals to Mankind."

OBSTETRICAL SOCIETY OF LONDON.—This evening, at 8, Specimens will be shown by Dr. Wiltshire, Dr. Brunton, Dr. Godson, and others.—Dr. J. Hickinbotham, "On Notes on a Case of Placenta Prævia complicated by a large Myoma."—Dr. Mansell Moullin, "On a Case of General Edema without Anasarca."—Dr. Barnes, "On a Note on the so-called Lithopedion."

### VACANCIES.

Belmullet Union, Knockalower Dispensary.—Medical Officer. Salary, £100. Election, June 6.

City Provident Dispensary.—Assistant Surgeon. Salary, £120, with midwifery fees extra. Applications to the Secretary, 164 Aldersgate Street, London, E.C.

Monaghan District Lunatic Asylum.—Assistant to Resident Medical Superintendent. Salary, £150, with furnished apartments, &c. Election, June 9. (See Advt.)

Sheffield Union.—Resident Assistant Medical Officer. Salary, £100, with board. Applications to the Clerk to the Guardians before June 8.

St. Mary's Hospital, Paddington.—Curator and Pathologist. Particulars on application to the Dean of the School.

Sussex County Lunatic Asylum.—Apothecary. Salary, £100, with board and residence. Applications to the Resident Medical Superintendent at Hayward's Heath, before June 15.

Worcester County Asylum.—Resident Medical Superintendent. Salary, £250 per annum. Applications to the Clerk to the Visitors, Sansome Place, Worcester.

### Births.

BOYD.—May 26, at Portland Terrace, Regent's Park, N.W. the wife of Surgeon H. Boyd, M.D., 14th Sikhs, of a son.

POIGNAND.—May 23, at 214 Upper Street, Islington, London, the wife of Malcolm Poignand, M.D., of a son.

### Deaths.

BARRETT.—May 25, at 12 High Street, Welshpool, Charlotte, the beloved wife of T. B. Barrett, M.B.C.S.

LYLE.—May 24, at 102 Eys Hill, Newcastle-on-Tyne, Robert Lyle, M.D.

FELLS.—May 7, on board the s.s. *Agamemnon*, in the Suez Canal, Bransby Cooper Fells, M.B.C.S.E., in his 56th year.

ROPER.—May 23, at Exeter, Charles H. Roper, M.B.C.S.E., L.S.A.L., aged 53.

The Subscription List will close on or before **THURSDAY** next, **JUNE 9th.**

# LAND MORTGAGE AND AGENCY OF FIJI, LIMITED.

**CAPITAL £500,000,**

**IN £50,000 SHARES OF £10 EACH. FIRST ISSUE £250,000.**

*Payable 2s. 6d. per Share on Application, 2s. 6d. on Allotment, and 15s. per Share in Three Months from date of Allotment.*

Further calls, if any, at intervals of not less than Three Months. It probably will not be necessary to call up more than Thirty Shillings or Two Pounds per Share, the intention being to issue Debentures, secured upon the uncalled Capital, and the properties mortgaged to the Company. Shareholders will, however, be allowed to pay up the balance uncalled on their Shares, and will receive 5 per cent. interest on such uncalled payments, such interest not to commence till three months after the date of allotment.

*Home Directors*—ROBERT FARQUHARSON, Esq, M.D., M.P., Finzean, Aboyne, Scotland, and Reform Club, S.W.

SIGMOND HOFFNUNG, Esq., Messrs. S. Hoffnung & Co., Merchants, Basinghall Street, London and Sydney and Brisbane.

NATHAN ALFRED NATHAN, Esq, Messrs. L. D. Nathan & Co., Merchants, Coleman Street, London, and Auckland, N.Z.

JAMES PELLATT RICKMAN, Esq., Messrs. Pellatt & Co., Falcon Glass Works, St. Bride Street, London.

WILLIAM ROBERTSON, Esq. (late D. & W. Robertson, Dundee), Holland Park, London.

NORMAN TRONSON, Esq., Hope Park, Bromley, Kent.

*Proposed Colonial Directors*—The Hon. J. C. SMITH, Member of the Legislative Council of Fiji, Managing Director.

WILLIAM HENNINGS, Esq., Imperial German Vice-Consul, Levuka, Fiji.

I. M. BROWER, Esq., late United States Consul, Levuka, Fiji.

*Bankers*—THE ALLIANCE BANK, LIMITED, Bartholomew Lane, London.

THE BRITISH LINEN COMPANY BANK, London, Edinburgh, and Branches.

THE UNION BANK OF AUSTRALIA, LIMITED, Levuka Branch, Fiji.

*Solicitors*—MESSRS. FOWLER & CO., 3 Victoria Street, Westminster, S.W.

*Brokers*—IN LONDON—MESSRS. G. H. & A. M. JAY, 17 Old Broad Street, E.C.

IN DUNDEE—MESSRS. WATSON & LOWSON.

IN ABERDEEN—MESSRS. JAS. BLACK & CO.

*Auditor*—JAMES B. LAURIE, Esq., Chartered Accountant, 62 Gresham Street, E.C.

*Manager and Secretary in London*—H. STONEHEWER COOPER, Esq.

*Offices*—3 VICTORIA STREET, WESTMINSTER ABBEY, S.W.

The objects of the Company are to make advances on real and other property in the Crown Colony of Fiji, and (subject to the sanction of a General Meeting of Shareholders) in the Islands adjacent thereto; also to transact Agency business connected with the Colony.

Fiji has made wonderful progress since 1874, when it became a British Colony. It offers an ample field to a Company, formed as the present one is after the plan of those Companies which in other Colonies have been so successful.

The Islands of Fiji are remarkably fertile. They present large attractions to enterprising men who desire to rapidly accumulate wealth. Considerable attention is being directed towards them from the neighbouring continent of Australia. They will in all probability become the commercial centre of the numerous islands known under the designation of Polynesia. As the Panama Canal progresses, increased attention will be directed to these islands, and its completion will bring them within little more than 30 days from London.

Sugar, coffee, tobacco, tea, copra, and other tropical products can be raised in Fiji under most favourable conditions of soil and climate, whilst there is abundance of land to be obtained with a Crown title.

The Company has been formed at the instance of very influential residents in Fiji, and most able local management will be secured.

The Company will lend money on the security of real or other property with a margin of about 50 per cent., and will carry on also a genuine Agency business, but will not enter into speculations on its own account.

The profits derivable from the land enable borrowers to offer very remunerative rates of interest for advances, for which there is a considerable demand.

It is proposed to obtain money on the Company's debentures at rates which will leave large profits on the lending of the money.

The Directors believe the Shareholders may confidently

rely on highly remunerative dividends, whilst the sound character of the business and its freedom from speculation may save them from risk.

The following table shows the result of similar undertakings:—

	Last Dividend, with Bonus
Trust and Agency Company of Australasia, Limited	20 per Cent.
Agricultural Company of Mauritius, Limited	20 "
Australian Mortgage Land and Finance Company, Limited	17½ "
New Zealand Trust and Loan Company, Limited	16 "
Mauritius Land Credit and Agency Company, Limited	15 "
New Zealand Loan and Mercantile Agency Company, Limited	15 "
Australian Agricultural Company	14 "
Scottish Australian Investment Company, Limited	13½ "
Otago and Southland Investment Company, Limited	12½ "
Scottish American Investment Company, Limited	12½ "
Scottish American Mortgage Company, Limited	10 "
North of Scotland Canadian Mortgage Company, Limited	10 "
No promotion money will be paid.	

The Directors have agreed to accept no remuneration for their services till five per cent. dividend is paid to the Shareholders.

The Directors have already received applications for £65,000 Capital.

### THE PRACTICAL TREATMENT OF DIPSOMANIA. (a)

By STEPHEN S. ALFORD, F.R.C.S.,  
Hon. Sec. Society for Promoting Legislation for the Cure of Habitual Drunkards.

BEFORE considering the practical treatment of dipsomania I will make a few remarks upon its predisposing and exciting causes, since no disease can be intelligently treated unless these are ascertained.

True dipsomania is undoubtedly a disordered condition of the nervous system, manifesting itself at first by functional derangements.

Dipsomania must not be confused with mere drunkenness for it soon becomes irresistible, and beyond the control of the ordinary will; often quite unconnected with temptation, and arising from a special individual condition; whereas drunkenness depends to a great extent on accidental outside allurements. Dipsomania may be hereditary or the result of an inherited nervous temperament, and transmitted like other family diseases. It is allied to such nervous complaints as insanity, hay fever, or sick headache, and like them is periodic in its attacks, and often accompanied by hallucinations, delusions, sleeplessness, tremors and nervous exhaustion.

Civilisation tends to produce this condition by causing nerve power to be prematurely used up. Among savage and half-civilised communities, though excessive drinking is often prevalent, the disease of Inebriety has scarcely been manifested. The exciting causes may be purely accidental, as from brain exhaustion following loss of property, or bereavement, or from physical injury, as in the case of sunstroke, or railway accident. The attack may be suddenly induced by certain climatic conditions, such as, sea air, east wind, dryness of the atmosphere, extremes of heat or cold, or in fact by anything disturb-

ing the harmony of the organisation, and thus arousing a hereditary tendency hitherto dormant. It may also be inadvertently lapsed into by a frequent resort to alcohol to sustain exhausted energy, and restore used-up nerve power. All diseases, whether of a local or constitutional character, which affect the system by perverting or lowering healthy nerve power, are liable to react in Inebriety. The effort to relieve exhaustion and remove a miserable, desponding condition, leads to a craving for alcohol which at the time cannot be restrained.

The successful treatment of dipsomania depends on a clear estimation of all circumstances and conditions connected with the case, as family antecedents, temperament, and personal history. Hereditary Inebriety is difficult to control, since the paroxysmal craving which can only be kept under by constant watchfulness and rigid abstinence from all alcoholic drinks is never completely lost. Voluntary effort on the part of the individual is necessary for the successful treatment of this class of inebriates, and they are generally anxious to conquer their inherited infatuation for alcohol, and will readily co-operate in any plan likely to ensure their emancipation.

Those who unwittingly lapse into Inebriety, and whose susceptible nervous temperament has an intolerance of alcoholic drinks, if they really wish to conquer this habit, can easily be treated successfully; especially if taken in an early stage. This class is not, however, so eager for recovery as the class in which Inebriety is hereditary, since the nerve exhaustion is greater, and the will power in abeyance, as if paralysed. But even these, when, after a few weeks of kind and judicious treatment, the immediate effect of the alcohol has passed off, gratefully consent to assist the efforts made to restore them, and willingly submit to all necessary restrictions. It is for this class particularly, that compulsory powers are required, to place them under control from the first, for while still suffering from the miseries of alcoholic depression, they are unwilling to entirely abandon its use.

When Inebriety arises from external causes, such as accidents, sunstroke, shocks, &c., the maniacal condition is most marked. Patients (thus attacked are incapable of acting and judging for themselves, and need early

(a) Read before the British Medical Temperance Association, May 27th, 1881.

restraint, not only for their own safety, but also for that of those associated with them. This unfortunate class of inebriates, as well as those whose disposition, when under the influence of alcohol is naturally fierce, are not responsible for their actions; their natural uncontrollable ferocity making them dangerous to themselves and others. Much of the quarrelling and violence in this country arises from persons highly susceptible and easily made incapable by alcohol, and really in an irresponsible state. Instead of punishing such for so-called crimes, a paternal government should take care of them, and protect the community from the disastrous effects of their wild actions.

Those who have become inebriates from companionship, and the habits and allurements of society, are allied to the mere drunkard, and are seldom willing to stop their drunken career unless compelled; disease, the result of their own intemperance, may arrest their course, but often too late for restoring what might have been a useful life. In all cases there must be the power of restraining the inebriate from alcohol; otherwise all efforts are futile.

The want of this power has baulked medical men in their efforts to treat inebriates. The infatuation is so intense, and the cunning efforts to obtain alcohol so persistent, that, without positive power of control, it is impossible to keep them from it. Hence, to secure success, individual liberty of action must for the time be sacrificed.

The imperfect Habitual Drunkards' Act of 1879 permits this power to be exercised, provided the inebriate consents voluntarily before two justices to submit himself to be placed under control in a licensed house, subject to Government inspection. Most hereditary inebriates will do this, as will also some from all classes of inebriates, but many are left uncared for, and allowed to ruin their families and destroy themselves; and, in their mad paroxysm, commit unconsciously all kinds of so-called crimes, including murder, for which, in this country, they receive capital punishment. What is needed is to obtain sufficient legislative power for the detention of all such incapable Dipsomaniacs in a well-managed home.

As soon as an inebriate is received into such a home, and until the alcoholic effects have passed off, he should be kept in bed, under medical treatment. All alcoholic drinks should be at once withheld; no harm will result from this total and sudden suspension of stimulants, not even in delirium tremens. The letting-down system, by gradually discontinuing alcohol, is unwise, as it feeds the craving, and hinders the recovery. The morbid craving will soon abate, but to relieve the intolerable sinking and nervous prostration acidulated drinks, barley water, buttermilk, and such-like diluents should be freely given for a few days; even if sickness occurs these drinks should be persevered with, for the sickness helps to cleanse the stomach. These drinks also act freely on the skin and kidneys, and thus have a beneficial effect on the secretions. Russian vapour baths, if they can be obtained, will promote this, and tend to soothe and allay the distressing restlessness, and to divert and occupy the attention. After a few days a little light food can be given, such as toast with beef tea, or some farinaceous preparation, but butcher's meat should for a time be avoided.

It would, perhaps, be better for confirmed inebriates at all times to take butchers' meat moderately, since it taxes the stomach, and creates a sinking feeling. Liebig considers that vegetarians, from chemical and physiological causes, would necessarily dislike and avoid alcohol.

During the early stage of treatment, if accompanied by wakefulness and delusions, bromide of potassium in large doses, with capsicum, frequently repeated, has a beneficial effect. The bromide soothes the agitated nervous system, and the capsicum allays the gastric craving. The ordinary anodynes, especially chloral hydrate, should be avoided. As soon as the alcoholic contamination has passed off, which it will require fully three or four weeks to effect, exercise and light occupation will be beneficial, and then the general moral treatment must be brought to

bear. Harshness will cause sullenness and obstinacy, and therefore, kindness and sympathy must be shown, and an effort made to arouse the better feelings, create a desire for recovery, and inspire a confidence that they can be restored if they will exert themselves, and second the efforts made on their behalf. The better part of the man being thus aroused, the alcoholic contamination eradicated, and the nervous system rallied, the influence of restored inmates, with whom they should now be allowed to associate, will be useful, helping to confirm a determination to throw off the old habits. Under judicious management and religious influence this improved condition may become permanent; in most cases nine or twelve months—in confirmed cases even some years—may be required to strengthen and confirm these habits. By degrees full liberty can be allowed the patients to go about as they like, at first only in company with a tried inmate, but on parole as regards alcoholic drinks. The habit of self-denial under temptation is thus practised, and becomes confirmed; and so valuable lives may be restored to their families and to society. Such I believe to be the most successful plan for the treatment of the inebriate.

To carry this out, it is absolutely necessary to have sufficient power of restraint during a paroxysm, as well as from the first, so as to put the inebriate under control, voluntarily or otherwise. No one will be more thankful afterwards for this suspension of their mad career.

During convalescence red cinchona bark strengthens and sustains nerve power; but when attacks of exhaustion and sinking arise, caffeine or coca will afford temporary relief; various nerve tonics, as quinine, arsenic, and strychnine, may also be given with benefit. The preparations of iron are not adapted for these cases except where there is anæmia. To prevent relapses, a lifelong abstinence from alcohol is absolutely necessary.

In America it is estimated that one-third of the inebriates under judicious treatment recover; a third are restored for a time, and the remaining third are unaffected. My experience convinces me that if the care of inebriates were more generally recognised, and effectual opportunities existed for their treatment in the early stages, a much larger proportion might be recovered. As it is, the percentage of recoveries will bear comparison with those from other diseases. In this country, for instance, it is estimated that only ten per cent. of those under treatment for insanity are restored to health. We must not so much depend upon purely medical treatment as on judicious management and kindness.

Religious influence is important in the second and subsequent stages of treatment, and to sustain the constant watchfulness necessary to maintain the total abstinence that must be religiously observed under all circumstances throughout life. This conquest of self, and keeping the morbid craving in subjection, few men can accomplish. At times, even after years of abstinence, the desire will be most distressing and overpowering. It is refreshing, under such circumstances, to recognise and experience the existence of a higher power, who will give the necessary help to all who really believe and earnestly ask for it. Permanent recoveries are uncertain without this divine help. Recognising the fact that craving for alcohol will arise from time to time, it is important to remove every opportunity of temptation; therefore, no inmate of an inebriate home should be allowed to possess money, or any valuables, without the express permission of the superintendent. As soon as they are able the patients should join in systematic occupations and amusements, for which purpose every inebriate home should have workshops and opportunities for games and sports, and these, as far as possible should be systematically arranged. Much of the benefit of hydropathic establishments depends on the systematic bathings and exercises. Inebriate homes would do well to adopt some of their plans. It is important that the treatment of inebriety should be commenced before the habit becomes too confirmed, and the physical and moral natures

thoroughly contaminated. If compulsory powers of control existed it would lead many voluntarily to place themselves early under restraint. These, knowing their inability to overcome their habit of inebriety, and that sooner or later they must submit to restraints, would adopt the more private plan of voluntary submission rather than run the risk of public exposure, particularly when they know that at the most the restraint could not exist for more than twelve months.

In America 94 per cent. of the inmates of inebriate homes have thus voluntarily given up their liberty; no doubt, in many cases, the knowledge of the compulsory power possessed by the State has conduced to this. But even in this country many have voluntarily submitted to control, recognising their inability to manage themselves. Well-managed homes find no difficulty in obtaining inmates, although they have no legal powers of detention. Yet thousands, not having the means to pay high terms, are left uncared-for. Many clergymen, and other professional men have applied to me for the opportunity of being admitted into a licensed inebriate home at a moderate charge. There is still the lower class, the source of most of the misery we find amongst us, who fill our work-houses and prisons, and to recover whom such persevering efforts are being made by temperance advocates. Are they to be left to destroy our country, and spread around them misery and distress, which a kind, firm control might prevent?

The people of this country, as a body, do not believe in inebriety as a disease. Even a medical man said to me the other day, "I would hang these drunken fellows up on every lamp-post."

Efforts are being made to establish in this country a Model Inebriate Home at a moderate charge to the inmates, so that, while restoring many of this neglected class, the public may be convinced that inebriety is a diseased condition, from which recovery can be obtained under proper treatment.

## ON TWO CASES OF CONSUMPTION.

By WILLIAM H. PEARSE, M.D., Edin.;

Senior Physician to the Plymouth Public Dispensary.

A. H., male, *æt* 20, came to the Dispensary on October 7th, 1880. He is a sailmaker's apprentice, living in the country, on the banks of the Tamar. His father, *æt* 39, is now in the second stage of phthisis; his father's sister died of phthisis at 30; his mother and her sister died of phthisis. He has spat blood, and has been ill since July last.

*Physical Type.*—Fair complexion, eyebrows heavy, upper lateral incisors small, nails large, hands and feet cold, scant whisker.

*Physical Signs.*—October 9th, 1880.—The left infra-clavicular region is dull on percussion, and has moist râles; the left infra-axillary region is dull on percussion, but has no moist râles. The right side is natural.

I ordered an out-of-door life, all and any food to which his fancies inclined him, and which included onions and pickles; also cod-liver oil, and the following mixture three times a day after meals, and which he has continued from October 9th, 1880, to the end of April, 1881:—

R. Cinchonid. sulph., gr. xx;  
Acid muriat. dil., ℥v;  
Liq. arsen. hydro., ℞c;  
Aq. maris., ℞lxxx;  
Mangan. sulph., gr. xx;  
Infus. quassia, ad., ℥x.

Twenty doses.

Nov. 20th.—Left infra-clavicular region is dull on percussion, and has moist râles.

Dec. 11th.—Appetite and general health much improved.

Jan. 27th.—No moist râles heard on the left side.

April 20th.—The left clavicular region has now fair resonance on percussion; the left infra-clavicular region has fair resonance on percussion; soft inspiratory sound and prolonged expiratory sound; no increased vocal resonance; no moist râles. The left infra-axillary region gave a little click-like sound once at the end of a deep breath; all else was natural. The right infra-clavicular region has fair resonance on percussion, and prolonged expiratory sound.

This patient is now bright and energetic. He says that he is well, and has resumed his labour as a sailmaker. There has been not only a lessening of the physical signs of phthisis, but a fair return of strength and energy has taken the place of the former lassitude.

E. G., female, *æt* 24, applied for treatment on January 14th, 1881; a fine woman; has had two children; no family history of phthisis; upper incisors regular, not decayed. Has had cough and much expectoration for some months. Has spat blood.

*Physical Signs.*—The right clavicular region is a little less resonant on percussion than the left; the right infra-clavicular region has not quite equal resonance on percussion to the left, but the resonance is fair; in the same region the inspiratory sound is rough, and the expiratory sound prolonged; also there is small crepitation; no increased vocal resonance. The left infra-clavicular region is not dull on percussion, has no prolonged expiratory sound, or increased vocal resonance.

I prescribed—

R. Quinæ sulph., gr. xxij;  
Acid muriat. dil. ℥iiss;  
Liq. arsen. hydro. ℞lxxx.  
Aq. ad. ℥x.

One twentieth part to be taken three times a day after meals. Also to take cod-liver oil.

The patient has continued the treatment about four months. The moist râles have diminished; no new physical signs have developed.

May 9th, 1881.—The left infra-clavicular has no moist râles, no prolonged expiratory sound, no increased vocal resonance. The right infra-clavicular region has fair resonance on percussion, about, or nearly equal to, that of the left; soft inspiratory sound, and soft prolonged expiratory sound; there are some small moist râles with the inspiratory sound. In January she complained of weakness, much hot flushing, and night sweats; also she had been wasting. She says that she is now stronger, better, and has gained much in flesh; she has, in fact, become very stout.

The improvement in these two cases may have been due to natural causes, irrespective of treatment—to those periodic tendencies to recovery which sometimes show; not the less the improvement has been very marked, and has been coincident with the treatment.

I am continually prescribing the combined muriatic acid, quinine, and arsenic treatment to a large number of those who are of the phthisical type, but whose cases have not advanced beyond the indigestion or bodily debility stages, and, with rare exceptions, with marked benefit. In the midst of other failures, it is a relief to find some more advanced cases benefited.

Until the spectrum or other analysis, shows us, on what deficiency in composition of the body, and thus of vital correlated energy, the early failure of healthy growth of the lung segments depends, we can only work by analogy; and it is on the ground, that phthisis, though generally a chronic disease in England, is an acute fever in some other countries, that it has co-relations with ague, and that anatomically, it is co-related with the skin system, that I have persistently, during some years, given a combination of arsenic, quinine, and muriatic acid, and especially to those numerous cases which have not yet advanced beyond the stages of indigestion, general weakness, or wasting.

## THE PRACTICAL EDUCATION OF THE PROFESSION.

By THOMAS LAFFAN, M.K.Q.C.P.I., M.R.C.S. Eng.,  
Physician to Greane Fever Hospital.

In former times it was the universal custom to put a youth, when taken from school, as an apprentice to a practitioner. Every general practitioner in the province had his two or three pupils. Those who aspired to become metropolitan practitioners, paid handsome fees to a London or Dublin hospital surgeon. This system produced men who were eminently practical. They obtained a thorough familiarity with drugs. It was not that kind of familiarity that students now obtain by the mere sight of drugs, from a distant bench in a *materia medica* theatre. They learned to become thoroughly conversant with their appearances, their uses, and their doses. A profound knowledge of their chemical reactions they had not, but they acquired enough of both for all practical purposes. Students thus brought up, learned faith in the medicines they used. Their faith may have been too large a one; but, at least, large faith is better than no faith. With us moderns, it is too much the custom to find in our text books a description of anything and everything but that which relates to fulness and variety of treatment. The lecturing system, with its scant contact with drugs, is largely responsible for this. No doubt we should be glad to see, in Scriptural phrase, everything proved with reference to the supposed virtues of drugs. We are asked to believe that medicines possess therapeutic virtues, which, with all respect to tradition, we would like to have some more complete proof of than we have at present. It is one thing, however, to desiderate a rational system of therapeutics, and another to disbelieve in them as much as we do. The youth, who was thus bound, was not sent, as we now send our youths, straight from the restraints of school into the furnace of city life. On the contrary he was placed under circumstances peculiarly suited to his years and inexperience. He had over him a master's eye, and a master's orders; and he was bred up in habits of discipline and subjection which were most useful to the shaping of his character. In large towns, under the present system, the youth is subjected to no restraint or discipline, and, as a result, only too many bitterly pay for the want of a restraining hand. On this point we cannot do better than quote some eminent authorities.

The first shall be that of an unfortunate man, but of a man who, more than any other in England, had opportunities for knowing the drawbacks occasioned by the present theoretical system of training. We refer to Mr. Baxter Langley. He says in his *Via Medica*:—"It appears to me a grave error to take a young man from school and plunge him at once into the theoretical studies of medical science; for it is absurd to expect that, during the short space of four years he shall learn the laws of physics, chemistry, botany, zoology, human and comparative anatomy, pathology, practice of medicine, surgery, midwifery, and medical jurisprudence. My experience leads me to the conviction that the most successful men are those who have some practical and general knowledge, and are able to observe and manipulate well before they enter upon their attendance at lectures. Hence, I am strongly convinced that a year or two well spent with a provincial surgeon is not time thrown away by the tyro in medicine. Students are apt to think that the whole object of their studies is to pass certain examinations, but thousands of men find out the burden and calamity of this mistake when they are called on to prove their practical acquaintance with their profession under some sudden and terrible emergency." Elsewhere, the same authority declares that men have been found unfit to undertake the duties of active practice, because of their want of such a training. We will quote one more gentleman. It is one who, though not so well known as Dr. Langley, speaks so much to the point as to imperatively require a place here. Dr. Roberts, of Port Maddock, President of the North Wales Branch of the British Medical Association, in the course of his address

on taking the chair, delivered the following observations:—

"I wish to draw the attention of the members to (in my opinion) the grave mistakes involved in the practical abolition of apprenticeship. I cannot believe that the five years indentured pupillage required by the regulations of the Society of Apothecaries, is a day too long, particularly if served with a general practitioner in a mixed practice. During that time, in his young years, the pupil not only learns practical pharmacy and the uses and doses of drugs, but becomes familiar with the routine of general practice in the surgery and consulting room, and has the great advantage of visiting patients and attending medical and obstetrical cases, not on his own responsibility, but with the feeling that he has always his principal to fall back upon in case of need, and his master to censure him in case of unskillfulness or neglect. He has ample opportunities of learning practical surgical duties, such as cupping, bleeding, dressing wounds, introducing catheters, &c., and also of treating fractures and dislocations. All this instruction he undergoes with the full knowledge that he is bound by his indentures to do his work, and that the law invests his master with large powers of coercion and correction in case of neglect or wilful default. A habit of discipline and self-control is thus early acquired, which, together with the practical experience already acquired, is most valuable to him in after-life. I might contrast the old system of apprenticeship, which I have imperfectly described, with the curriculum now too much in vogue. The student goes straight from school to a metropolitan or other large town to attend lectures and observe the practice of hospitals. He is thus thrown, at a tender age, among all the temptations of a big town. He attends the lectures, which he is for a long time unable to follow. He daily walks through the wards of the hospital in a crowd of other students at the heels of one of the physicians or surgeons, and hears the patients interrogated, sees their tongues examined, their pulses felt, and his attention may be occasionally drawn to cases of rare or special kind, but seldom or ever to the common disorders of suffering humanity, which he will mostly have to treat in ordinary practice. He hears prescriptions dictated which to him are all double Dutch, as he has no practical acquaintance with any of the drugs or the compounding of them. He witnesses operations performed in the theatre, but is not allowed to try his prentice hand upon anything except the subjects in the dissecting-room. He perhaps reads hard, and goes up for his examinations—inflated and crammed with theoretical knowledge, it might be—

'A bookful blockhead, ignorantly read,  
With loads of learned lumber in his head.'

After spending, in this manner, portions of his four short years in acquiring knowledge, he receives his diploma, and is launched upon his unfortunate countrymen and countrywomen as a fully-qualified practitioner. Of course, in nine cases out of ten, medical men, so educated, have the sense to perceive that they must learn the practical part of their duties, and they forthwith advertise for assistantships, condescending to accept salaries of from £100 to £120 a year, and their board and lodging, for being taught the real, or, at any rate, the most important part of their profession. But that is not all—and I hear the same complaint from many of my professional friends. The qualified assistant, so educated, is generally too conceited and self-sufficient to acknowledge his ignorance, or to consult his employer as an apprentice would. The employer, therefore, not only pays for a light which does not shine, but is constantly kept anxious, and on the *qui vive*, lest his qualified assistant, through some maltreatment of a case, may bring him into trouble. I think, therefore, that those gentlemen ought, in justice, to pay handsome premiums rather than receive salaries for the opportunity afforded them of becoming practical practitioners, ere establishing themselves in practice on their own responsibility. I must apologise for dwelling so much upon the subject, but I cannot help feeling strongly that something ought to be done, either to return to the

old and well-tryed system of apprenticeship, which, as you know, still obtains in the profession of the law, and most trades and callings of the higher sort, or to adopt some other plan by which the same advantages of real, practical medical education in early life shall be secured."

We have reproduced the above extracts because they entirely agree with our own views, and have the additional weight of the great experience of those who have uttered them. Years ago we published similar views, and we rejoice to think that the medical authorities are now coming round to them. At the last meeting of the Medical Council it was resolved that one year out of the four might be spent as the apprentice to a country practitioner. The metropolitan interest vigorously opposed this, as it always does everything opposed to its own special interest. They sought to oblige the student to spend the entire four years at some medical school, but, happily, the good sense and public spirit of the majority defeated them. Sir James Paget declared, on that occasion, that had he a son commencing the profession, the first thing he would be to send him, for at least a twelvemonth, to a country practitioner. The Council also recommended that the licensing bodies should require from each candidate for final examination a certificate of his having been, for six months, an hospital dresser or an assistant, with care of patients, to some general practitioner. The choice left opened up a field to country practitioners which, in Ireland, has been entirely closed to them since the apprenticeship system was done away with.

Sir Dominic Corrigan opposed this on the grounds that it was not desirable to entrust the care of patients to unqualified persons. We agree with him on this point, and therefore regret that another amendment, introducing the "part care," was not carried. This, after all, is an objection of a purely theoretical kind, so far as this country is concerned, for, with us, no apprentice will be entrusted with the exclusive care of patients. The late Professor Parkes objected to this system on the ground that theory should precede practice. An objection coming from such an authority is entitled to consideration. This, however, is one which does not hold water. Great part of the knowledge which apprentices acquire, either requires no antecedent knowledge of theory for its acquisition, or such a knowledge of theory as most certainly may be acquired in the country. Take, for instance, the knowledge of pharmacy and of drugs. What theoretic information, not at the pupil's disposal, is required to learn compounding, and to learn also the appearances and doses of drugs? We grant that a complete knowledge of the chemical and botanical parts of materia medica cannot be obtained outside the lecture-room and laboratory. Two sixpenny primers will supply pupils with easily-mastered information, in both botany and chemistry, sufficient to enable them to understand a goodly part of these subjects. Such students, when they subsequently find their way to a materia medica lecture, will not be in the unknown land that students differently brought up will find themselves in. On the contrary, they will be merely adding to, and methodising an existing stock of knowledge, not laying in a new, and but half-understood load altogether. Talking of sixpenny primers, when we, ourselves, commenced materia medica—and we did so, to our grief, not in the way we are here recommending—it was a sixpenny primer that enabled us to follow those portions of the subject that we have before alluded to. Other students, who did not take to the primers, found themselves unable to follow one-half of the subject. Dr. Parkes' views are based on the supposition that botany and chemistry should be learned before materia medica; but how many students do really know them, either before or after that subject? Enough, for our point, that the heart may be broken in an important subject during the days of a country apprenticeship; that the knowledge so acquired will be much more substantial, indeed, than that picked up in a lecture-theatre, and that the balance will be acquired in the theatre in half the proportion of time

required by the entirely uninitiated student. Then look at the compounding. What kind of compounding is, or can be, taught at a Dublin or London hospital? It is a poorly-attended hospital that has not sixty students. What may the sixtieth part of the compounding of such an hospital be deemed worth? Ought we to consider it worth anything? We think not? and we are more positive in our opinion, inasmuch as that, to aggravate matters, a few months during the summer is the only time that these students have, at their disposal, for the acquisition of the knowledge.

Then let us look at hospital practice. What theory is required in order to pass a catheter? What theory, without practice, is sufficient to pass one? We have known the picked men, under the system which now prevails, obtain their diplomas without being able to pass a catheter, or being able to do, with anything like ordinary skill, twenty other small things, which no practical examination can provide for, and which, taken together, form the bigger part of daily practice. An apprentice can read both medicine and surgery under his master, not with the same advantage as if he knew the antecedent subjects, but with this advantage, that he will master a goodly portion of both, and that he will subsequently visit the lecture-theatre, only to clear up some portions, and add to, and systematise the whole. How different the position of the student who has not had such training. The lecture is, for a long time, as strange to him as if it were delivered in an unknown tongue; and when he does begin to understand it, it makes a very much less solid and permanent impression on his mind than it would if he had been differently brought up. An apprentice also obtains a familiarity with the appearance, the diagnosis, the prognosis, and the treatment of disease, which places him quite at home in the wards of the metropolitan hospital, and enables him to profit more in one month than the mere green youth in twelve by the methodical teaching, and special instruction of his new teachers. We know that we shall scandalise some learned theorist by talking about a student learning the treatment of disease before he has been able to learn Virchow's latest novelties; but, we ask, how much of our treatment is founded on such a rational basis as to be beyond the ken of the tyro? The practical knowledge of hospital minutiae, which can be acquired by the pupil of a country practitioner, can never be acquired by three out of four of your be-lectured students. An amusing attempt is being made by the authorities of two great London hospitals to meet this practical difficulty by appointing the preposterous number of 150 medical and surgical dressers to attend the patients of a single hospital. Comment is unnecessary. The difficulty can be met in one way only, and that is, by taking provincial hospitals into partnership in the work of education. This need in nowise interfere with metropolitan interests, or add to the expense of education. One-half the money would suffice that is now wasted by the loafer, who takes four years to scramble through his diplomas. The industrious man who, despite the regulations of the Medical Council, gets through in two years, or rather in twenty-seven months, and who spends the balance of the four years roaming about town, would also find it more to his advantage to pay a little in money at the commencement of his studies for a provincial training than to incur a larger loss, not in money alone, but, it may be in shame and self-reproach in after years. There is one subject which, of all others, might be supposed to be wholly learned at a medical school, and that is anatomy. Now, no opinion is more erroneous than this. We have had some experience in anatomical teaching, and were always satisfied if the pick of our class knew the entire bones after three months' hard work. Now, we have also known apprentices come to town bringing with them a thorough knowledge of all the osseous parts of anatomy. Here was a good three months saved, and something more, for such students at once were able to take in a larger amount of knowledge in the dissecting room than their utterly ignorant fellow students. Nay, more, while the latter

were wading through the bones, the former were mastering a more advanced part of their subject, and at the end of the session it becomes a difference, not of three months, but almost of an entire year. Nor is this all. Nothing is more easy than for a country student to obtain, through the medium of a stray post-mortem, a few anatomical preparations, and contributions from the lower animals, enough knowledge of the viscera, &c., to enable him fully to profit by the hospital opportunities at his disposal for the study of internal diseases. Let us, in conclusion, hope that the Medical Council will insist on the licensing bodies giving effect to its recommendation in this matter. By all means let some condition be annexed that will oblige the master to intelligently instruct his pupils, and the pupils to profit by the instruction of the master. Let us have no shams; no farcical attempts to stretch the practical resources of metropolitan hospitals far beyond the point to which they are capable of extension.

Finally, let us have no certificates certifying to apprenticeships which have never been served. If this new change be loyally carried out we shall rear a race of students very different from the rowdy element so largely entering into our present numbers, and a race of practical men who will combine a knowledge of their business with a knowledge of the theories upon which it is based.

## Clinical Records.

### ST. MARY'S HOSPITAL.

Under the care of MR. A. T. NORTON.

*Necrosis of Ungual Phalanx of Thumb—Excision of Diseased Bone—Sarcomatous Growth from Wound—Amputation at Carpo-metacarpal Joint.*

Notes by MR. HANDFIELD JONES.

PATIENT, a thin, sallow-looking woman, æt. 55, was admitted into St. Mary's Hospital on February 15th, 1881, suffering with necrosis of the unguinal phalanx of the right thumb. Five years ago, without any assignable cause, the nail commenced to split down its centre, and the patient was soon able to pass a needle down between the nail and the matrix without causing herself any pain, though on so doing a small amount of fluid escaped. No further bad result followed; the nail grew naturally again; and patient thought no more of the occurrence until two years ago, when, according to the woman's account, the thumb began to grow bad again and fester, at the same time becoming intolerably offensive. She seems to have allowed matters to go on without seeking aid, until at last the pain became so excessive that she was forced to apply for relief.

On admission, the top of the thumb presented all the appearances of underlying dead bone, and a probe lightly introduced at once touched the necrosed surface. In the right axilla a lump, consisting apparently of enlarged glands, was felt but the patient stated that this had existed for some years, and, though at one time it had been tender and painful, yet now it did not cause the least trouble.

On February 17th the dead bone was removed, and the surrounding tissues being found healthy the operation wound was dressed in the usual way. Nothing noteworthy occurred until the first week in March, except that the wound did not heal well. There was an undue quantity of suppuration, as well as an unnatural amount of pain and tenderness in the thumb. Early in March, however, exuberant granulations began to sprout up, thereby separating the lips of the wound; at the same time pain became very intense, and the end of the thumb became covered before long with a large fungous, sloughy mass which bled freely on the slightest pressure. Red oxide of mercury was applied and constant poulticing ordered, but without effecting any good.

On March 31st Mr. Norton removed the whole of the thumb, under Listerian precautions; and by the middle of April the patient was able to leave the hospital, the wound having healed up without any complication.

On examining the diseased thumb after the operation, a large sarcomatous growth was seen sprouting from the head

of the second phalanx outside the periosteum; extending also down the sides of the bone for a short distance past its centre. The bone itself seemed to be undergoing a process of degeneration. When the patient left the hospital, and, indeed, during the whole of her stay in the ward, there had not been the slightest symptom of pain or tenderness in the axilla, though the lump in that region had been carefully watched; but on the patient's returning on May 28th to show her hand, marked changes were noticeable. The mass which had been about the size of a pigeon's egg, circumscribed and movable, was now occupying the whole of the axilla, firm and fixed, and had apparently made its way under the pectoral muscles. There could be no doubt, but that the growth was of a sarcomatous nature and from its extent and connections any idea of removal was manifestly out of the question. The cicatrix of the operation wound was still perfectly sound and healthy.

## Special.

### REPORTS ON THE SANITARY CONDITION AND ADMINISTRATION OF THE ISLE OF WIGHT.

*East Cowes.*—The town sewerred in 1862; the sewers not yet flushed or ventilated; engineering mistakes, bad workmanship, and bad management connected with these works. A great part of the new town still unsewered, the houses drained into cesspits, and these overflowing cause nuisances. The water supply scanty, interrupted; one source "little liable to pollution except at seasons of very high tides." Scavenging fairly performed. The houses occupied by the poorer classes for the most part in a decent condition. In an estimated population of 2,058 there were recorded, in five years, 11 cases of fever, viz.—in 1875, 1; in 1876, 4; in 1877, 2; in 1878, 2; in 1879, 2. In 1876 there occurred 11 cases of scarlatina. No diarrhoea during the five years. Among paupers in the same period only one case of fever, and it enteric, occurring in 1879. No scarlatina recorded during the five years among this class. It is added, however, "there is no doubt that enteric fever has prevailed at East Cowes to a considerable extent," also that its prevalence has been justly attributed to defects described in the drainage and water supply.

*West Cowes.*—The chief escape for sewer air is at the inlets of drains in and about the houses. Water supply "must be regarded as suspicious in quality." Yet the medical officer of health does not appear to have reported against it. It is obtained chiefly from works of the local board. Scavenging generally well performed. Some houses occupied by the poor dirty, dilapidated, setting cleanliness at defiance. In five years seventeen fatal cases of fever occurred among the ordinary population (5,730) namely, 1 in 1875, 4 in 1876, 4 in 1877, 2 in 1878, and 6 in 1879. Scarlatina prevailed in 1876 and 1877, v. z., 39 cases in the former year, and 8 in the latter. Diarrhoea gave only 3 cases, namely, 2 in 1877, and in 1878. Among the pauper class no case of fever was noted in either of the three years first named. In 1878 there were 20 (8 enteric); in 1879 19 (8 enteric). Scarlatina produced 6 cases in 1879. None in the previous four years. Of the pauper cases in 1878 it is stated that 8 were of unquestionable enteric fever, and 12 doubtful—probably mild cases of the same disease; in 1879 8 cases of enteric fever, and 11 of other or doubtful character. The full number of cases in all classes in the town may be believed, therefore, to have been very considerable.

*Newport.*—Banks of filthy mud exposed at low tide in the estuary. In some parts of the town the courts narrow and confined. The town generally well built and open; partly sewerred, but sewer ventilation in abeyance; street gullies stopped, the only escape for sewer air at the inlets of drains in and about houses. Water-closets in general use, in some places cesspit privies. Parts occupied by the poor ill drained, ill paved, and dirty. Pigs kept in dirty places by the poorer classes. In an estimated population of 6,947 there were 9 deaths by scarlatina. Except in 1875, deaths by diarrhoea occurred in every year of the period, namely—1 in 1876, 4 in 1877, 7 in 1878, and 4 in 1879. Among paupers the cases of fever were: in 1875, none; in 1876, 6 (of which one was enteric); 1877, 4 (3 enteric); 1877, 10 (8 enteric); 1879, 19 (10 enteric). In this class no scarlatina was recorded in 1875; in 1876 there were 24 cases; in

1877, 2; in 1878, 2; and in 1879, 2. The reports state that "with the absolute certainty of the inhabitants being exposed to the influence of drain and sewer air, the occurrence of enteric fever can be no matter of astonishment;" also, that were it not for the constant supply of good water, this disease *would probably* have been more prevalent than it has been.

*Ryde*.—Up to five years ago sewers unventilated. Since then they have been extended, improved, and ventilated; now complaints made regarding offensiveness from the ventilators. Generally speaking, the house drainage is efficient, yet no ventilation of the house drains. There *must be* access of sewer and drain air into the dwelling houses. Houses of the poorer classes generally clean; their privies outside, themselves in dirty, ill-paved, ill-drained positions. Water supply generally good, a few houses supplied by wells, the water of them "necessarily suspicious" in quality. Pigs and other animals in some parts kept in a filthy state. In an estimated population of 11,260, there were recorded 24 fatal cases of fever in five years, namely—7 in 1875, 4 in 1876, 8 in 1877, 1 in 1878, and 4 in 1879. Scarletina prevailed in two of the five years, causing 11 deaths in 1876, and 5 in 1877. Diarrhoea caused 15 deaths in 1875, 3 in 1876, 4 in 1877, 2 in 1878, and 3 in 1879. Among pauper classes no case of fever was recorded either in 1875 or 1876. In 1877 there occurred 27 (all enteric); in 1878, 26 (20 enteric); and in 1879, 25 (all enteric). Among the same class scarlatina, unrecorded in 1875 and 1876, produced 22 cases in 1877, 12 in 1878, and 1 in 1879. With reference to the prevalence of fever, the remark occurs that "*perhaps* the fact of due precaution to prevent the access of sewer and drain air to the interior and about houses *may have been one cause* of its prevalence."

*St. Helen's*.—Generally well sewered. Sewers at Oakfield originally provided with ventilators, but as offensive odours from ventilators arose, they have been closed. At Oakfield, accumulations of filth in yards of many dwellings, evidently of old standing, "*calculated to endanger health*." During the last few years pure water from Ryde Water Works instead of the previous faulty supply. Several houses in Oakfield dirty, their surroundings; insanitary, yards unpaved and undrained. Population unstated. The fatal cases of fever recorded in five years 10, namely—4 in 1875, 5 in 1876, 1 in 1877, none in 1878 or in 1879. In 1876, 6 deaths by scarlatina, 2 in 1877, none in other years of the period. Diarrhoea deaths: 7 in 1875, 2 in 1876, 1 in 1877, 2 in 1878, and 2 in 1879. Pauper cases, however, were: in 1875, 11 (all enteric); 1876, 30 (29 enteric); 1877, 16 (all enteric); in 1878, 12 (all enteric); in 1879, "several cases." Among the pauper classes the cases of scarlatina were 2 in 1875, 52 in 1876, a few in 1877, 3 in 1878, and 9 in 1879. In the reports no record occurs of diarrhoea in the latter class, yet in the second quarter of 1878 there was a sharp outbreak (about 20 cases) of choleraic diarrhoea in the village of St. Helen's. The medical officer of health inquired into it, but failed to discover its cause. According to the report, it appears *probable* that the works of sewerage (in part), the improvement of the water supply, especially at Oakfield, have made an impression upon the sickness and mortality by fever.

*Sandown*.—Several wells closed on account of their pollution, complaints against the public water supply as to its dirty condition and *apparent* unfitness for use, "of a muddy greenish colour," the sediment presenting under the microscope "cellular structures of a vegetable nature with floating bodies of animal origin." It is *believed* to be filtered before use. The Yar, from Niton and Wroxall, polluted with sewage and excrement; sand filtration would improve its quality, but it would still be a dangerous water. Scavenging of the district imperfectly performed. Estimated population 2,320. Of fever among persons belonging to the district 3 fatal cases in 5 years, namely—2 in 1877, and 1 in 1878; none in either of the other years since, 1875 to 1879 inclusive. Of scarlatina, 5 deaths in 1875, 1 in 1876, none in either of the other places. Of diarrhoea, 2 in 1875, 2 in 1876, 3 in each of the three following. Pauper cases of this disease in 1875 none recorded, in 1876, 34 (other or doubtful sorts); in 1877, 2 (ditto); in 1878, 8 (ditto); in 1879, 7 (ditto). Of scarlatina, 11 cases in 1876, 1 in 1877, 2 in 1879. None in either of the other years. "It is an unhappy custom of some practitioners to keep the word 'enteric' or 'typhoid' to signify strongly marked and typical cases of the disease." "Either the so-called fevers

most abundant when scarlatina was passing away were themselves examples of that disease, or the cases were real instances of *enteric* fever, but not recorded as such."

*Shanklin*.—Thoroughly sewered when built upon; sewers insufficiently ventilated. Prior to four years ago house drains badly laid, and imperfectly connected. A fourth of water closets in the town unsupplied with water, such closets outside the houses. In some houses the same cistern supplies the closet and drinking water, in a few a connection exists between them. Houses of the poorer classes generally well looked after; but the state of Ribstone Court very unsatisfactory. Water supply for the most part very defective, the supply intermittent; about one-third of all houses supplied from shallow wells liable to contamination through porous soil from imperfect drains. In estimated population of 2,035, fatal cases of fever recorded in 5 years 2, namely—1 in 1875, and 1 in 1876; in the other years either no returns or no cases. In each of these two years one death by diarrhoea. No death by scarlatina is recorded, but returns wanting for 1877 and 1878. Among pauper classes there were recorded 10 cases of fever in 1875, 9 in 1876, 4 in 1877, 7 in 1878, and 9 in 1879. Scarletina: 1 case in 1876, and 3 in 1878. Of diarrhoea, none during the period. The information regarding fever described as "most indefinite." "There *would seem* no room for doubt that whether severe or mild, enteric fever is of only too common occurrence in Shanklin." The reports by the medical officer of health "characterised by a too roseate tinge."

*Ventnor*.—Sewers in various parts broken or choked; offensive odours from outfall nearest the pier and esplanade. Within the last six years charcoal ventilators introduced, but this method a failure, and sewer air enters the houses. Sewers never flushed. Water closets in general use, their pipes unventilated. Most of the houses supplied with water by the company, others from private shallow wells, which "*cannot be free from considerable suspicion* of dangerous pollution." The general reservoirs "exposed to absorb sewer air conducted to it through the waste pipe." Population 4,841. Sixteen deaths by fever in 5 years, namely—2 in 1875, 2 in 1876, 4 in 1877, 2 in 1878, and 4 in 1879. Only one fatal case of *scarlatina* during the period, namely, 1879; 4 of *diarrhoea*, namely, 1 in 1876, 2 in 1878, and 1 in 1879. No similar statistics regarding paupers. The prevalence of enteric fever in Ventnor is stated to be "a matter of notoriety." In most instances the disease has been contracted in the place. The cases have been attributed "either to the use of polluted well water, or to the admission of sewer air into the houses, mainly by the latter cause." Another *unrecognised cause* has most probably been the pollution of the company's water by the absorption of sewer air. But the difficulty against this theory is "that we should have expected the disease to have appeared on a larger scale among the inhabitants and visitors in the place."

## Translations.

### ON THE VALUE OF OPERATIONS WHICH INVOLVE INCISION OF THE MEMBRANA TYMPANI.

By Dr. J. POLLAK, of Vienna.

Translated by W. DOUGLAS HEMMING, F.R.C.S. Ed.,  
Bournemouth.

(Continued from page 114.)

II.—ANOMALIES of tension of the membrana tympani, catarrhal swelling of the mucous membrane of the tube, stricture of the same, ulceration and cicatrisation of the pharyngeal orifice of the tube (syphilis), tumours in the naso-pharynx, (polypi, adenoid vegetations, hypertrophy of the pharyngeal tonsil), paralysis of the palate muscles, hinder or render quite impossible the ventilation of the tympanum. It results that the air in the tympanum becomes partially absorbed and rarefied, the now preponderating pressure of the external air forces the membrane inwards, rendering it abnormally tense; the point of insertion of the tendon of the tensor tympani approaches the inner wall of the tympanum, the tendon, therefore, becomes relaxed, as a result of which secondary contraction of the muscle, and shortening of the tendon, ensues.

Objectively the pathological condition shows itself by pro-

jection of the short process, perspective foreshortening of the handle of the malleus, and the formation of two folds in the membrana tympani, of which one proceeding from the short process backwards appears especially well marked, and, therefore, is of great importance diagnostically and therapeutically.

Its form and direction varies much. Whilst in many cases it appears like a broad bow, directed backwards and downwards, to pass over to the periphery of the membrane, in other cases it forms a straight tendon, tightly stretched horizontally directly backwards, or like an arch, it bridges over, the handle of the malleus lying beneath it in a pointed angle, so that between them there is a difference of depth of 1 mm., or thereabouts. The condition of the membrane takes part in the investigation with Siegle's pneumatic speculum, in the opening of the Eustachian tube, whilst with an impervious tube there will only be perceived slight vibration of the membrane. When the air in the meatus is alternately condensed and rarefied by the above-mentioned speculum, after an injection of air has been made there will be perceived a much greater mobility of the membrane, as in the normal state.

The disturbances of hearing, which are produced by excessive tension of the membrane, are very variable, and often bear proportionately little relation to the amount of the latter. Besides the disturbance of the function of hearing, there occur subjective sensations of sound, a feeling of fulness and obstruction in the ears, a sense of weight and oppression in the head, and attacks of giddiness.

It is possible in a large number of cases, by treating the fundamental malady, by inflation of air, by injection of medicated fluids into the tube and tympanum, by other therapeutic methods, which it would be beyond the scope of this paper to describe in detail, to induce a relaxation of the membrane; in many, especially chronic cases, however, we are not in a position by the above-mentioned therapeutic methods, to attain an improvement in the position of the membrane and the ossicles. The improvement in hearing is very slight, and soon passes off, and the subjective tinnitus becomes, by its persistence, very troublesome to the patient.

In this form of tension of the membrane, Gruber recommends multiple perforations of the membrane; Politzer, and later Lucae, perforation of the posterior fold. Of the first-mentioned operation, I have no experience; the latter I have performed in 35 cases. Of the technicalities of the operation, it may be observed that it should be performed with a small double-edged, lance-shaped needle. The section should be made  $1\frac{1}{2}$  to 2 mm. behind the short process vertical to the fold. The section often causes a squeaking sound. I have generally observed no ill effects. Only in one case was the chorda tympani cut through, without any ill result, since after three days, the normal relations were completely restored.

The results obtained were the following:—With the exception of one patient, in whom, from the long duration of the disease, the imperfect perception through the bones of the head had led to a consecutive labyrinth affection, there took place after the operation a significant improvement in the hearing power, and complete disappearance, or considerable diminution in the subjective aural symptoms. Unfortunately, 23 of the patients operated upon, since, for two or three weeks, the improvement of hearing remained, removed themselves from further observation.

Whether these are to be considered as improved, or entirely cured, I can scarcely say, as six of the other cases operated upon showed relapses after the expiration of three or four months. A repetition of the operation produced a similar result. In this way I have operated upon the same ear of one young lady seven times. In five cases I was able to verify the maintenance of the improved hearing after two or three years. Interesting is the result in the case of Herr Schuster, on the posterior superior segment of whose left membrana tympani Professor Gruber operated with galvano-cautery, on account of relaxation. The posterior fold was extended backwards, like a thin tense tendon, and was not changed in position by inflation of air. After the incision it disappeared completely. From these results I draw the conclusion that incision of the posterior fold is not an absolutely certain means for removing long-standing abnormal tension of the membrane, but that the operation, on account of its probability of success, and its easy practicability, should be undertaken experimentally in all these cases in which the abnormal tension of the membrane, and the resulting disturbance of the hearing apparatus cannot be reached by any other local or medicinal treatment.

After long duration of the inward curvatures, and tension

of the membrane, produced by the preponderating external air pressure, there gradually occurs partial or entire thinning and relaxation of the membrane. Partial thinning shows itself as dark, more or less, circumscribed sunken spots, easily confounded with cicatrices of the membrane. Frequently the thinning and relaxation is observed at the posterior superior quadrant of the membrane. The distinct conspicuousness of the stapedia-incudal joint, in favourable cases also of the stapedia, and of the niche of the fenestra rotunda, and the apparent projection of the first from the plane of the membrane, makes up in such cases a characteristic picture, which changes essentially on inflation.

The relaxed, glass-like, transparent part, projects forward in the form of a bag, hides the hitherto visible part of the inner wall of the tympanum, and sometimes even the malleus handle, to sink in again after a short time, yielding to the external air pressure. If the relaxed membrane is drawn in *in toto* (collapsus membrana tympani), as a result of its thinness it allows the inequalities of the inner wall of the tympanum to be clearly perceived. By fluctuation of the air pressure in the drum, which, in rare cases, may be produced even by the movements of respiration, it is curved outwards, and more tightly stretched, returning on the cessation of the pressure in folds to its former position. The disturbance of function stands in direct relation to the size of the relaxed part, and may be explained by the diminished power of vibration of the membrane, and the damage which ensues to the acoustically important portions of the tympanum.

Relaxation of the membrane, however, may also be brought about by preponderance of air pressure in the tympanum, produced by abuse of inflation (Valsalva experiment; all forms of air douche) in a widely open tube, a form of relaxation, for the diagnosis of which we are indebted to the labours of Professor Grüber. Ocular examination does not reveal such striking changes of texture as in the form of relaxation above described.

If, however, we cause a patient, having this kind of relaxation of membrane, to perform Valsalva's experiment, we shall see the posterior superior segment markedly protruded; if we examine it with a Siegle's speculum, the drumhead appears, on the alternate condensation and rarefaction of the air, like a loosely hanging membrane. Of very great importance and interest is examination with the tuning-fork. Whilst a sound ear, during the Valsalva experiment, when the tension of the membrane is normal, hears the vibrating tuning-fork, held before the ear, worse, but when placed on the skull, better, the reverse is found in relaxation. Persons affected with a high degree of relaxation of the membrane, come to know instinctively how to perform the Valsalva experiment in the interest of improved hearing, and they exercise it; hence the relaxation is increased, and the intra-labyrinthine pressure heightened.

As regards treatment, it is only when a great part, or the whole membrane, is concerned in the relaxation, that operative procedure is required. Attempts may be made by pencilling with nitrate of silver, or dropping in a solution of the same (Toynbee), or by blowing in astringents to the inner side of the membrane, to set up reactive inflammation in the membrane, so with a similar object is proposed multiple perforation of the membrane. The last named is recommended only in small atrophic sunken spots of the membrane, like cicatrices. Grüber uses, as a last resource only, galvanocaustic application to a part of the affected tissue.

(To be continued.)

## Transactions of Societies.

### THE MEDICAL TEMPERANCE ASSOCIATION.

THE fifth annual meeting of this Association was held on May 27th, in the rooms of the Medical Society of London, Dr. B. W. RICHARDSON, F.R.S., in the Chair.

Dr. J. S. RIDGE, the honorary secretary, read the Report, which referred to the papers read at the quarterly meetings, to the action taken at the International Medical Congress at Brussels in August last, and the Conference at Bristol in October; also, to the adoption of Dr. Norman Kerr's proposition that the dinner tickets at the British Medical Association's Annual Dinner should be exclusive of wine.

It also stated that the Local Government Board had in-

stituted an inquiry into the increase of mortality in the West Derby Union Workhouse, alleged to have occurred through the decrease of the use of alcohol therein.

The members of the Association had increased to 250, and the associates (medical students) to 16.

After the installation of the re-elected officers,

Dr. RICHARDSON returned thanks, and said there were enough medical abstainers to increase their numbers to 500, or even 1,000.

S. S. ALFORD, Esq., then read an able paper,

ON THE PRACTICAL TREATMENT OF DIPSOMANIA,

which will be found on page 483.

In the discussion that followed,

Dr. EYTON JONES said he had entirely lost faith in any remedial measures that were not of a coercive character. He had asked a great number of inebriates to submit themselves to some repressive measure, but while two or three had done so the majority had exhibited the same slyness with respect to this matter as they did in obtaining stimulants; and as inebriety was largely increasing amongst females, he felt that coercion was the only thing to look to. He had acted as a magistrate for nearly fifteen years, but found that great suspicion existed on the part of the public, and that if coercion were established in this matter medical men would be found who would be biassed in such a way as to send persons to these asylums who did not properly come under the class of dipsomaniacs. He thought that a mode of examination might be established which would put the question beyond doubt. He was further of opinion that the law should provide that dipsomaniacs should be proclaimed before two magistrates upon testimony of a most reliable character; and then the public at large would come to regard coercive measures as being of greater value than moral measures. If Dr. Norman Kerr's statistics were reliable—and he had proved that nearly 50,000 lives were lost annually in this country, directly owing to intemperance—what became of the few cases of dipsomaniacs who were cured and returned to their families. He believed the only way of preventing such people from ultimately being sent to gaol for committing crime was to assert the majesty of the law in the individual before he became a criminal.

Dr. NORMAN KERR thought the great point they ought to look at was one of which the clergy and other moral reformers had lost sight. Over and above the moral and physical degradation there was in a great many cases something more than the merely moral or social aspect of the question—viz., the disease behind. Until the people of this country understood that drunkenness was the result of a physical narcotic poison operating upon the physical, mental, and moral nature, they would fail to grapple with the subject. It was essential always to bear in mind that there was no danger in suddenly cutting off the supply of alcohol; but he could not agree with the writer of the paper that any amount of beefsteak in the world would give anybody an appetite for liquor, nor that vegetarianism was desirable. Dipsomania was quite an artificial disease, and if alcoholic liquors were abstained from it would soon die out. With regard to the bark cure, red bark and other tonics were good things; but of the so-called bark cure and other things of the kind which came from Chicago he could not speak in too strong terms of disapproval, the whole being a sham—a system of quackery. It was essential to remember that more than medical treatment was necessary. At present there was no licensed home in the country to which he could recommend a patient. The Dalrymple Home would soon be ready, and he believed that would have a very good effect.

Dr. DRYSDALE felt a great deal of doubt as to the possibility of locking-up people because they were inebriated. He was strongly opposed to the vegetarian tendency of the paper, neither could he agree with the essayist in the enormous influence of theology in curing dipsomania. As medical officer to the Rescue Society he thought that women were quite amenable to successful treatment in regard to drunkenness, and also in regard to other vices.

Dr. ALFRED CARPENTER, J.P. (Croydon), said that dipsomania was a disease capable of being cured, and that was the great point we had to keep before us. As a medical man, and as a magistrate, he had had repeated applications made to him to commit individuals to some place where

they would be kept from drink, but up to 1879 the law of England did not allow such an asylum to exist. He trusted that everybody interested in this question, and particularly medical men, would support the Dalrymple Home. They would then be able to show Parliament what had been done at present; and that by proper treatment it was possible to effect the absolute cure of dipsomania.

Dr. BRANSON said the keystone to the whole matter was prevention, and the education of the people to the terrible disease brought about by intemperance.

On the motion of Dr. James Edmunds, the debate was adjourned to the 24th of June, at the same place, at four o'clock, Mr. Alford, in the meantime, being thanked for his paper.

## The Mineral Waters of Europe.

THE "MEDICAL PRESS"

ANALYTICAL REPORTS ON THE PRINCIPAL BOTTLED WATERS.

By CHARLES C. R. TICHBORNE, LL.D., F.C.S., F.I.C.,  
President of the Pharmaceutical Society of Ireland, Lecturer  
on Chemistry, Carmichael School of Medicine, &c.

WITH

NOTES ON THEIR THERAPEUTICAL USES.

By PROSSER JAMES, M.D., M.R.C.P. Lond.,  
Lecturer on Materia Medica and Therapeutics at the London  
Hospital, Physician to the Hospital for Diseases of the  
Throat, &c.

(Continued from page 470.)

THERAPEUTICS OF ALKALINE WATERS—continued.

FROM our estimate of the relative qualities of the alkalies we would suggest that large doses of potash salts should not be continued without great care. This brings us to another point in the treatment of acute rheumatism by alkalies. We believe that the mistake most frequently made is to continue the remedy too long. Suppose it is decided in any given case, that it is desirable to alkalinise the system, then it is better to do so at once, and potash is to be preferred to soda. Large doses may be given for a day or two without fear; in fact, until the urine is alkaline; but having reached that point, only just enough potash should be given to maintain the secretion neutral for a few days. After this it may be allowed to be feebly acid. The good to be obtained from the alkali in such cases, has already for the most part been secured. If the justice of these remarks be admitted, their application to the subject in hand will be obvious, from the fact that alkaline waters are often recommended in chronic rheumatism in which they should be prescribed with circumspection. Probably, the introduction of salicin will largely displace the alkaline treatment of acute rheumatism, but there will also be cases in which the alkalies seem to be indicated, and then they can be tried in the manner we have recommended; perhaps, too, as preliminary to salicin, salicylic acid, or the salicylates.

To return from this special case to the more general application of alkalies. It is impossible to overlook their simple chemical effect on the primæ viæ. Indeed, for this they are often prescribed, without reference to ulterior action, and in such cases it is that we have most often met with the abuse of this class of remedy. Our readers are,

however, likely to be alive to this evil, and we may therefore pass on. In the blood the alkalies appear as albuminates, phosphates, and carbonates. The solution of fibrin and albumen is closely connected with their presence, and Liebig thought that carbonate of soda might be regarded as a sort of conveyer of carbonic acid to the lungs. Organic acids and carbo-hydrates and probably some of the more important constituents of the blood are oxidised by these agents, and this accounts for the wasting sometimes seen from their use, especially in fat patients. It would seem not improbable that we can render the blood unusually alkaline, by a careful administration of successive doses, graduated according to the rate of elimination, but the rapidity with which these remedies are carried out of the system, renders it impossible to do this by doses at long intervals. Here is sufficient food for thought to any one who has fallen into mere routine practice. Besides making oxidation more active, alkalies stimulate osmosis. There can be no doubt that, as continual interchanges take place between the blood and the tissues, we may carry on our work still further by the long continued use of alkalies, and it is probably in this way, rather than in the action in the blood, that the wasting we have alluded to is brought about. When it is advisable to increase tissue-metamorphosis, it may be accomplished in this manner, though the reader will, perhaps, think that there are other more natural methods of reaching this end. Whether such increased metamorphosis leads to the more rapid formation of new tissue is a question which most would answer in the affirmative, but we cannot forget that so desirable a consummation may be sometimes prevented by the very remedy employed. If it impair digestion and assimilation, what other results can ensue? This has happened again and again, but may be avoided by a wise plan of administering the remedy. It is the *proper* use of alkalies, and chiefly of the bicarbonate of soda, that the physicians of Vichy, and other alkaline spas have never seen do any mischief. But their improper use may be fraught with *peril*, and the late M. Gubler related several instances of alkaline cachexia to the Paris Academy. We have already indicated that this might easily occur, and in doing so, have pointed out the manner in which it is most probably brought about.

Something must be added as to the special indications for administering the waters of this group. Their alkaline property is the most obvious, and to that the chief importance has always been attached. Whether we speak of them as antacids or as agents assisting to maintain the normal alkaline reactions within the body, their use in functional diseases of the alimentary canal is closely related to the employment of soda in other forms. In dyspepsia and diarrhoea this is readily seen, as well as in other disorders of the stomach and bowels. It is by no means proved that we can increase the normal quantity of soda in the bile, and yet it is believed by some that gall stones have been dissolved in this way. If there be no foundation for this belief, it seems certain that many cases of jaundice—chiefly those depending on catarrh of the cystic duct—have been relieved by alkaline waters. Much the same may be said of functional liver derangements; and competent observers record cases in which palpable enlargement of this organ has diminished during a course of these waters.

Such cases are usually treated by the thermal springs, and the influence of the quantities of warm fluid, as well as other circumstances, must not be lost sight of. In lithiasis and in gout these waters are also largely employed, although soda is not considered the most appropriate alkali in these conditions. It is probably by hastening tissue changes that they are efficacious, for the view that they merely neutralise excess of uric acid is insufficient, and this effect is even disputed. In catarrh of mucous membranes these waters are useful. As far as the alimentary membrane is concerned, this may be thought due to the antacid effect, but it can hardly be the case in the respiratory tract, where these waters, and more markedly those which also contain chloride of sodium, prove serviceable. Catarrh of the bladder, and other parts of the genito-urinary tract, may also be treated by these waters, but in such cases caution is to be enjoined. In diabetes alkaline waters must not be given in too large doses, or continued too long at a time. We have refrained from going too deeply into the differences of the several alkalies, because in mineral waters we have practically only to do with soda. The action of bicarbonate of soda, the chief ingredient, is however, sometimes modified by the presence of chloride of sodium, as well as the other constituents, and whether alone or in combination the effect varies with the dose, the degree of concentration of the water, the period of the day when it is taken—a point which resolves itself into the state of the digestion at the time—and, lastly, the temperature at which it is drunk. With regard to this last point something has been said in a former report. Here, therefore, it need only be remarked that warmth favours the absorption of the soda, and the warm waters are most in repute when it is desired to affect the fluids of the body, but cold springs are recommended where the local effect on the *primal viæ* is aimed at. Some of the bottled waters may be warmed to imitate as far as may be the conditions in which they are taken at the springs. We have now only to note the principal waters of this class.

*Vichy* is the sovereign of alkaline spas. It possesses both warm and cold springs; its waters are well adapted for bottling, and are, in fact, exported in enormous quantities. Professor Tichborne finds less soda in the bottled waters than might have been supposed from previous analyses; but still, the quantity is so great that Vichy retains its pre-eminence as the strongest alkaline spa. The number and varying qualities of its springs enable those skilled in their use to rely entirely upon them when mineral waters of a powerful alkaline nature are required. It is always to be remembered that these waters are potent medicines.

The *Grande grille* is a hot spring, temp. 105 deg. Fahr., and perhaps more used than any on the spot. It is specially used in diseases of the abdominal viscera, in the cachexia induced by residence in hot climates, in obesity, and whenever it is desired to stimulate absorption. In some cases of biliary calculi Vichy is useful. Diseases of the spleen are treated, but with much less benefit. Patients with gravel or other urinary affections resort in great numbers to Vichy. In gout, the *Celestins* spring, which is cold (temp. 58 deg. Fahr.), and by far the most pleasant to drink, is in most repute. It bears exportation well, and, as a naturally cold water, seems

well adapted for bottling. The writer has prescribed it for many years. The *Hauterive* has recently replaced it to a considerable extent. We may, however, observe that all the springs possess the same general character, that the distinctions offered are by no means absolute, that one may usually replace the other, that the differences observed at the springs are mostly due to the various temperatures, and that, so far as regards the exported waters, all may be considered of equal value. In disorders of the stomach it is unnecessary to point out the indications for alkalies. In diabetes Vichy has been of great service, but the treatment is usually carried out at the spa. A season has often been followed by excellent results, and, during the intervals between their visits, patients may at intervals drink the bottled waters, with the circumspection indicated above. As the writer has previously published a pamphlet (a) on these waters which has passed through four editions, he need say no more on the subject here.

(To be continued.)

"SALUS POPULI SUPREMA LEX.

WEDNESDAY, JUNE 8, 1881.

**SANITATION IN THE ISLE OF WIGHT.**

MUCH has of late years been done in the Isle of Wight to improve the sewerage of towns and private houses

and to provide for the inhabitants a supply of pure water. That public health, comfort, and convenience have gained thereby is not to be doubted. But how far the occurrence of that particular form of disease which has come to be looked upon as directly and alone due to neglect in both these respects has undergone corresponding decrease is a point on which the reports referred to in another column furnish information of a somewhat negative kind. In these reports the statistical tables given do not in all instances convey information exactly similar throughout the series, or of so precise a nature as could be desired. Taking them, however, as they stand, and selecting more immediately the subject of fever, the following are the results shown: the eight districts into which the island is divided have an estimated total population of 66,219, omitting corrections for the more recent census. In the tables given the numbers of *deaths* among the general population, and of *cases* among the pauper classes appear side by side; thus the conditions indicated differ from each other; but the general results over a period of five years have nevertheless their value. In the general population the deaths by fever as recorded, were for the years respectively from 1875 to 1879—22, 24, 23, 11, and 20. It is apparent, however, that in some respects information on this point is defective, thus as regards Shanklin, in 1877 and 1878 a mark of interrogation takes the place of arithmetical figures. With reference to the pauper classes the number of *cases* in each of the five years already mentioned are respectively 28, 81, 54, 86, and 80. That these figures are but extremely "approximate" is indicated by the marks of interrogation in returns quoted by the indefinite expression "several," as applied to St. Helens in 1879, whereas in each of the four preceding years and counting backwards, the figures for that place were 12, 16, 30, and 11; at Ryde, regarding which the statistical information, interrogative in 1875 and 1876, gives respectively 27, 26, and 25 cases in 1879, and so on. But as a general result, the tables indicate that whereas in 1875 there were recorded 22 deaths by fever in the general population, there occurred 20 in 1879; other years varying from 11 in 1878 to 24 in 1876; the *cases* among paupers 28 in 1875 to 80 in 1879; the variation between 54 and 86 in the intermediate years as already stated. Upon the whole, then, combining the statistics of mortality and of cases, the totals are found to vary from 40 in 1875 to 105 in 1876, 77 in 1877, 97 in 1878, and 100 in 1879, so that, taking the data as given, the result is that a very great and alarming increase has taken place in the prevalence of fever in the Isle of Wight during the five years ending with 1879. According to the same report great improvements, as already observed, had been in progress during those five years in respect to "sanitary" work in that island. Surely, therefore, the conclusion is justifiable that the causes upon which the occurrence and prevalence of *fever* depends are to be sought for in other conditions than those alone to which such measures have during that period been directed.

With reference to particular localities information does not appear as to whether fever has really prevailed to a greater extent in such as are faulty in "sanitary" conditions than in those that are more satisfactory. That

this point is taken for granted appears from the remarks made regarding Newport, that "with the absolute certainty of the inhabitants being exposed to the influence of drain and sewer air, the occurrence of enteric fever can be no matter of astonishment." But no allusion occurs to other conditions which necessarily affect the inhabitants of such localities, as their own state of poverty, social position, habits, and manner of life, all of which go far to determine the nature and type of disease among such classes.

So also with regard to water. Where direct connection cannot be traced between contaminated water and the occurrence of fever, such connection is assumed, notwithstanding also that argument is against it. At Ventnor, for example, we read that cases of fever have been attributed "either to the use of polluted water, or to the admission of sewer air into the houses;" also that "another unrecognised cause has *most probably* been the pollution of the company's water by the absorption of sewer air." Conjectural in the extreme; and that it was considered so by the reporter himself appears from his own remarks:—"The only difficulty in admitting this to have been a means of distribution for enteric fever in Ventnor is, that we should have expected the disease to have appeared on a larger scale among the inhabitants and visitors in the place." Of course, it would have so appeared.

The report describes the unfortunate but very natural result which has arisen from the strong tendency manifested of late years to inculcate one set of conditions with regard to causation of specific forms of fever, to the almost complete exclusion of every other circumstance and condition whether inherent in individuals or affecting them from without. It is expressly stated that guardians assume Medical Officers of Health to be superior sort of Inspectors of Nuisances; also that they perform much of the work proper to the latter functionary, to the detriment to their ability to advise comprehensively, and from a proper point of view upon the larger sanitary wants of the district. It is further, and most properly added, "the conditions endangering health which require medical experience for their apprehension and medical intelligence for their remedy, are those which it is the legitimate work of the Medical Officer of Health to bring to light and advise upon." Just so. It is very well to observe cleanliness of person, surroundings, and in mode of life generally. But to limit attention to matters of simple conservancy, as is now too much the fashion of the day, is to cramp and paralyse the higher functions of that official.

#### THE GENERAL MEETING OF THE IRISH COLLEGE OF SURGEONS.

THIS important meeting, which has been looked forward to for some time past as the occasion which would decide the future of medical teaching and examination in Ireland, was held on Saturday last. It was known that a great effort would be made to adjourn *sine die* the new scheme of education and examination which had been matured and adopted by the Council of the College, and which was now submitted to the Fellows for their approval,

and much influence had been brought to bear to bring the provincial Fellows to Dublin to vote *pro* or *con* on this proposition. The result was an unusually large assembly of the College, numbering 84. The great majority of the Fellows were, as might be expected, metropolitan, the proportion being 65 Dublin residents, and 19 provincial visitors. The chair was occupied by the President, Dr. McClintock, and after the usual preliminaries that gentleman referred to the Annual Report, and pointed out that, while it was submitted by the Council for discussion, it was not the custom of the College that its adoption should be moved; nor was it competent to the Fellows to reject it, though they were invited to discuss any or every subject referred to therein. A debate followed, upon a motion submitted by Dr. Jacob, and seconded by Dr. Martin, of Portlaw, to the effect that "The method of communicating the proceedings of the Council by an Annual Report is insufficient and unsatisfactory;" and it was, for the second time, recommended to the Council to arrange for the issue "at quarterly periods of an accurate and complete *procès* of its business."

On this resolution the President made a statement setting forth the reasons of the Council for not complying with the former recommendation of the College and for the omission of any notice of the matter from the report. The College then voted, the resolution being carried by a majority of 26 to 11, eight of the minority being members of Council, and many Fellows not voting. After some criticism by Dr. J. Bellew Kelly, of Drogheda, upon the method of keeping the College accounts, Dr. Mapother moved, and Dr. Tufnell seconded a resolution, the purport of which was that the Council should frame a scheme of education and examination conformable with the Medical Council recommendations, and should consider the propriety of deferring further action on the matter until other licensing bodies had adopted a similar system. This resolution gave rise to a prolonged and animated debate, in which Dr. Macnamara, Dr. William Carte, Dr. M. A. Ward, Dr. F. A. Nixon, and other Fellows spoke against the proposed scheme, and Dr. Kidd, Dr. Barton, Dr. Bennett, Dr. Martin, of Portlaw, Dr. Jones, of Cork, and Dr. Jacob spoke in its favour. On a division the voting was—for Dr. Mapother's resolution, 27; against it, 31. Non-voters, 26. The resolution was, therefore, lost, and the proposed Scheme practically approved by the College.

This vote we take to be equivalent to a final affirmation of a reform of the existing educational system in Ireland, which will be of incalculable advantage to the student, to the Irish surgeon of the future, and, we fully believe, to the College itself. The practical working of the system of examination remains to be settled, and, this being done, the new system will probably come into effect before November next, and be obligatory on all students commencing study after that date.

The College "Club" dinner was held in the evening and brought together between sixty and seventy members and guests. The President occupied the chair, and had on his right and left the President of the College of Physicians, Sir Edward Sinclair, the President of the Irish Medical Association, the High Sheriff of the City, Sir George B. Owens, and other leaders of the profession. The *reunion* was in all respects quite successful.

## Notes on Current Topics.

### The Chelsea Hospital for Women.

Among the events of the season may be ranked the Old English Fancy Fair to be held in the Albert Hall at Kensington, the opening of which takes place to-day (Wednesday). The object of the bazaar is to augment the resources of the Hospital for Women at Chelsea, an institution in which the Princess of Wales exhibited a strong interest by laying some time ago the foundation-stone of additions to its buildings. The arrangements in connection with the "Fayre" are of the most complete and elaborate kind, and the scene presented by the Hall when converted to serve the purpose of an old English market place will be one that will well repay a visit. On the opening day the presence of several members of the royal family, including T.R.H. the Prince and Princess of Wales, the Princess Christian, &c., &c., will tend to increase the efficiency of existing institutions.

### The Influence of Light on Ants.

THE indefatigable researches of Sir John Lubbock have made the features of ant economy all but thoroughly familiar to the great number of working naturalists at home and abroad, and so well is his claim identified with discoveries in connection with these little animals that the scientific zoologist unconsciously associates all the knowledge of them he possesses with Sir John's name. In a long series of papers read at intervals before the Linnæan Society of London, and dealing with the subject of ants, Sir John Lubbock has done very much to clear up doubtful points in comparative physiology and psychology; in many ways, too, the suggestions associated with his conclusions have assisted towards awakening the spirit of research in other and younger minds, a result to be very much desired. The latest contribution from Sir John Lubbock, read on Thursday last, deals with the influence of light on ants. He satisfied himself that the different rays of the spectrum acts on them in a different manner from that in which they affect us; for instance, that ants are specially sensitive to the violet ray. If an ants' nest be disturbed, the ants soon carry their grubs and chrysalises underground again to a place of safety. Sir John availing himself of this habit, placed some ants with larvæ and pupæ between two plates of glass about an eighth of an inch apart, a distance which leaves just room enough for the ants to move about freely. He found that if he covered over part of the glass with any opaque substance the young were always carried into the part thus darkened, and that if he placed side by side a pale yellow glass and one of deep violet, the young were always carried under the former, showing that though the light yellow was much more transparent to our eyes, it was, on the contrary, much less so to the ants. From this point he further proceeded to test the effect on them of ultra-violet rays, which to human eyes are invisible. For this purpose he covered certain nests in two parts, one with violet glass, the other with a flat bottle containing sulphate of quinine and bisulphide of carbon, both highly diathermic bodies. In every case larvæ were carried to beneath the clear coverings, the dark violet portion being carefully shunned.

Again, he threw a spectrum into a similar nest, and found that if the ants had to choose between placing their young into the ultra-violet rays or in the red, they preferred the latter. He infers, therefore, that the ants perceive the ultra-violet rays which to our eyes are quite invisible. But everyone will not quite follow the implied conclusion that these rays are necessarily experienced as rays of light, an assumption urged by Sir John Lubbock, who speculates on the probability of the mixed colours presenting other than the white familiar to human eyes. The experiments are not yet by any means completely described, but so far they have a high degree of interest for the physiologist, and there can be little doubt that, difficult though it may be to exactly define its direction, the influence of such inquiry is beneficial not to science simply, but also to progress in its practical application in medicine.

### The Spread of Small-pox.

It is with increasing alarm that we witness the steady growth in the weekly fatalities from small-pox. The vigorous attempt that might have been made at an earlier period of the epidemic, is no longer possible now, and there remains the miserable conviction that however greatly the outbreak may extend, it has been largely helped to this end by the inconsiderate and selfish clamourings of those who refused to hear or attend to reason's voice. We never defended the principle of creating centres of small-pox treatment in neighbourhoods already populated to any extent; on the contrary, we have again and again urged the necessity for building small-pox hospitals where isolation might be practically ensured; but notwithstanding this, at a time when every moment was of consequence, it was surely unwise to close what might, by affording shelter to more or fewer cases of disease, have served a while longer the purpose for fulfilling which it had been condemned, that, namely, of being a small-pox hospital. Now, of all times, when any day the bounds within which infection is at present confined, may be overpast beyond all power to recover, and an all but universal infection of susceptible persons ensue, is the most inappropriate for continuing the bickerings that seem to be the natural atmosphere surrounding the unfortunate Asylums Board. By and bye, when the violence of the visitation is abated, the subject can be fully and safely discussed; meanwhile, let aid, rather than obstruction, be offered to increase the efficiency of existing institutions.

### Civic Presentation to Dr. Miller, of Londonderry.

THE Corporation and citizens of Derry were engaged last week in paying a well merited tribute of respect to a worthy and much-esteemed member of our profession, who has figured for a very long period in the history of the City of Derry. In November last Dr. Miller, after spending close on a half a century in the Town Council, signified his intention of retiring, owing to his declining years. In consequence of this intimation the Council, in the following month, unanimously adopted an address; and in which allusion was made to the great services he had rendered, in his civic and professional capacity, to the community. Sir Edward Reid, Mayor, presided at the presentation, and conveyed the address

of the Corporation, beautifully engrossed and illuminated, and handsomely bound in morocco. At the same time the chief magistrate was made the medium of handing to Dr. Miller the spontaneous gift of the citizens in the shape of a chaste centre-piece of solid silver. Dr. Miller was elected alderman in the ancient Corporation of the City as far back as 1832. While that Corporation existed he was twice mayor, and after the reconstruction of the civic body he held the Chief Magistracy for no less than five times. He served in the civic office for upwards of forty-eight years, and during that period did much to improve the sanitation of the city. Few men have been so long engaged in public life as Dr. Miller, and we could hardly find an instance of one who has been so much associated with the people, both politically and socially, so highly honoured by all sections of the community.

#### Registration.

THE Medical Council has issued an important notice on the subject of registration of medical practitioners. Upon the wording of this notice, it will be recollected, a dispute took place between the Branch Councils and the General Council in London, which occupied many months, and was the subject of sundry law opinions. The announcement now sets forth that every registered medical practitioner should be careful to send to the *Branch Registrar by whom he was originally registered* immediate notice of any change in his address, in order that his correct address may be duly inserted in the "Medical Register," otherwise, by Section 14 of the Medical Act (1858), such practitioner is liable to have his name erased from the "Medical Register," and to lose the right to hold certain appointments, to sign valid certificates, or to recover, in any court of law, charges for professional aid, advice, and visits, and the cost of any medicines or other medical or surgical appliances rendered or supplied by him to his patients. Every registered medical practitioner should also send to the *Registrar by whom he was originally registered* notice of any addition to his qualification that he may wish to be inserted in the "Medical Register."

#### International Medical Congress.

A LIST of upwards of one thousand intending members has already been prepared, and 130 medical men, including many leaders of the profession, both in London and the provinces have paid their membership subscriptions and inscribed their names on the register of the Congress. Prof. Maurice Raynaud, the giver of the French address has chosen for his subject "*Le scepticisme en médecine au temps passé et au temps présent,*" and from his well known ability in this direction we may confidently expect a great literary treat. A large number of papers for the various sections continue to flow in from home and abroad and are undergoing translation preparatory to being published at the time of the Congress. The committee have received a grant of £26 5s. to the general fund from the Royal College of Surgeons in Edinburgh, this raising the total sum received from the various corporate bodies to £292 15s. An effort has been made to induce the railway companies to reduce their fares to

gentleman proposing to attend the Congress, but without success, although our Foreign Minister Earl Granville addressed the ambassadors at the various European courts on the subject. An exception has been made by the South Eastern, and London, Chatham, and Dover companies and the Chemin de Fer du Nord of France, who have most generously granted permission for visitors to travel from Paris to London and back for a single fare. The Norwegian passenger steamers from Christiania to England will carry our Scandinavian confères for a single far for the double journey.

#### Follies of Fashion.

APART from the perennial folly of tight lacing, to which attention was recently drawn by us, and the equally ridiculous and abominable practice of deforming the feet by encasing them in shoes only half their natural size, the last decade has not witnessed anything in dress-foolishness that will compare with the indecent and dangerous thing called "crinoline," an invention that would have done credit to the most evil-minded of all disreputable geniuses. It is with no ordinary feelings of disgust and loathing that men, to whom there remains any sense of propriety, regard the prospect of a possible reusucitation of this dead monster; and it may not yet be too late to urge upon those unfortunate beings who will by following the directors of fashion, submit themselves to the horrors of this hideous cage, the grave injury they will thus inflict, not on themselves alone, but on the whole of the civilised world, by consenting to adopt the decrees of silly frivolity. Better by far were it that an attempt should be faithfully made once more to recover the native shape which all but a very few women of this generation are entirely without claim to, by dressing after the model set by the Ladies Dress Reform Association. The follies of fashion are the greatest evil modern society has to combat, and its effort to resist it are at best, but flimsy and unreal.

#### Germes of Malignant Charbon.

IN a recent note to the Academy of Sciences of Paris (*Comptes Rendus*, No. 5, 1881), M. Pasteur states that there is a farm near Senlis where many sheep annually perish of malignant charbon. These sheep have been interred in a walled garden; in one part none have been placed for twelve years. About two ounces of the surface earth was taken from this part; it was well washed and guinea pigs inoculated with the smallest particles; the animals rapidly perished of malignant charbon. Then at the farm seven sheep were each afternoon placed in this part of the garden; as there was no grass the sheep were fed at the stable, with the rest of the flock; notwithstanding this, two of the sheep soon perished of charbon, while the five others, and the rest of the flock, did not suffer. Thus two sheep perished through the habit they have of turning over the earth, and yet no diseased animal had been interred in the spot for twelve years. In this part of the garden were grown some of the vegetables used on the farm, and but one of the farm people suffered; he had been attacked by malignant pustule, which had not proved fatal. These facts would seem to prove that vegetable combustion and assimilation do not destroy the

germs of certain microscopic organisms which may be contained in manure or in the carcasses of dead animals.

#### Death of an Army Medical Veteran.

IN Surgeon-Major John Coughlan, who died last week at Kingstown, co. Dublin, has passed away the oldest medical officer in the British service. His duties brought him frequently into communication with the Iron Duke during the Peninsular campaign, and indeed the narrative of his life during the great military operations in the first quarter of the present century would fill a volume. He entered the service as assistant surgeon on the 9th November, 1812. Few men had seen more active service endured more hardships, or had more narrow escapes. He served in several regiments for a period of thirty-five years and afterwards in the 86th, from which he retired on half-pay in 1844. He was the oldest medical officer in the service, having a short time since completed his 90th year. He had two sons surgeons in the army who died on foreign service.

#### Rupture of Internal Organs without Apparent External Lesion.

WE read of two such cases in the reports of the Société Anatomique (Paris). The first occurred in the service of M. Duplay; the patient had been caught between a waggon and a lamp post. There seemed to be no external contusion, but the patient complained of intense pain in the hypochondrium. At the autopsy a complete rupture of the kidney was found, with a torn condition of the spleen; there was effusion of blood between the layers of the omentum and mesentery.

In the second case, a workman was thrown from a team; his hernia escaped from beneath the truss which maintained it, at the moment of the accident. There was no sign of abdominal contusion, and the symptoms simulated those of strangulated hernia. At the autopsy, a small opening, about the size of a dime, was found in the small intestine; there was effusion of the intestinal contents into the cavity of the pelvis, and generalised peritonitis, but no strangulation of the intestine.

#### Scrofula and Tuberculosis.

M. GRAUCHER recently made a communication on this subject to the Société Médicale des Hospitiaux, a long and careful analysis of which, by M. G. Artaud, appears in *La France Médicale*. M. Graucher considers the question from four points of view, etiological, experimental, anatomico-pathological, and clinical, and arrives at the following conclusions, with which he terminates his memoir: 1. Tubercle is a fibro-caseous neoplasm, the evolution of which takes place by successive stages; this evolution may be incomplete, and be arrested in the early stages, complete and produced in a few months, or last through life. 2. Pathological anatomy and experimental pathology are in accord in ranking with tuberculosis, under the title of local tuberculous, most of the affections called scrofulous. 3. Lupus and superficial inflammation of the skin and mucous membrane, will probably in their turn be ranked in the same category. 4. The necessities of practice not allowing us to mix together all the tubercular

affections, it is convenient to keep the word *scrofula* to designate slight and curable tubercular lesions.

#### Bromide of Ethyl in Hysteria and Epilepsy.

MM. BOURNEVILLE and Ollier have been studying the action of bromide of ethyl on hysterical and epileptic patients, and have arrived at the following conclusions (*Le Praticien*):—1. Papillary dilatation at the commencement of the inhalation of the bromide is not constant. 2. Complete muscular resolution is exceptional. 3. Anæsthesia is produced in very variable degrees according to the subjects. 4. The temperature, the secretions, the general state do not appear to be in any way modified. 5. The pulse and respiration are slightly accelerated. 6. There may be produced more or less marked trembling of the limbs during the inhalation, but it does not continue after it. 7. Hysterical attacks are generally easily stopped by bromide of ethyl. 8. Attacks of epilepsy may sometimes be arrested by giving the remedy during the period of tonic spasm; more often the inhalation has no effect. 9. In epilepsy the regular employment of the remedy by daily inhalation for one or two months, markedly decreases the frequency of the attack.

#### The Administration of Purgatives by Hypodermic Injection.

MUCH attention has been directed in Germany and Italy to finding some means of replacing tartar emetic, ipecacuanha, and saline and vegetable purgatives of all kinds, by simple hypodermic injections of apomorpha and aloin (the alkaloid of socotrine aloes). Just as with a subcutaneous injection of apomorpha effects of nausea and vomiting have been obtained, so with a warm aqueous solution of aloin (1-25th) injected in the thigh or fore-arm, there have soon been produced true symptoms of purgation. In these cases the remedy does not act by direct contact with the gastro-intestinal mucous membrane. These, as *Paris Medical* says, are very singular facts which call for serious study and verification.

#### Sisters of Charity as Nurses.

THE plan has been actively pushed in Paris to dispense with the services of the sisters of charity in the hospitals, and substitute paid nurses. About one-third of the medical officers of the hospitals are opposed to the change, and have protested against it. The Municipal Council is for the change by a heavy majority, and are about to open a "Municipal School for Nurses" at the La Pitié Hospital. One objection urged against the sisters, is their proselytising tendencies. From our own observations of the class which fill the Paris hospital, such, or any kind of religious admonition would not be amiss.

#### Death from Bromide of Ethyl.

DR. R. J. LEVIs, of Philadelphia, the distinguished advocate of bromide of ethyl, recently lost a patient under this anæsthetic at the Jefferson Medical College Hospital, Philadelphia. The patient was about to be operated upon for stone in the bladder, but died as the first incision was being made. Dr. Levis was present during the administration of the anæsthetic, and no doubt exercised every known precaution.

### Nitrite of Amyl in Cystic Catarrh.

A REMARKABLE disinfectant action of nitrite of amyl on the urine has been noticed by Dr. Weiser, and he employs it for this effect in chronic catarrh of the bladder (*Le Praticien*). Three drops of nitrite of amyl in 300 grammes of tepid water are injected into the bladder twice a day. For disinfection and preservation of the urine nitrite of amyl is preferable to carbolic acid, when the presence and search for albumen do not present an obstacle.

### Variations of Population in Ireland.

ALTHOUGH the alterations in the population of the Irish towns as compared with the Census of 1871 are not yet accurately known; yet it has been ascertained that in Dublin, Belfast, Londonderry, Newry, and Dundalk the population has increased, and therefore the birth- and death-rates are overstated when calculated according to the returns of 1891. On the other hand, it appears that a decrease has taken place in the populations of Limerick, Waterford, Drogheda, Galway, Clonmel, and some other towns in Ireland.

DR. TANNER has found a rival in a Mr. John Griscom, who recently began a forty-five days' fast at Chicago, under medical supervision.

SMALL-POX caused 100 more deaths in London and its outer ring of suburban districts last week, one in Brighton, and one in Norwich, but no fatal case of this disease was registered in any of the seventeen other large provincial towns.

THE following is the subject for the Jacksonian Prize of the Royal College of Surgeons of England for the ensuing year; viz., Wounds and other Injuries of Nerves, their Symptoms, Pathology, and Treatment. For the present year, it is the Pathology and Surgical Treatment of Diseases of the Hip-Joint.

THE annual rates of mortality last week in the principal large towns of the United Kingdom per 1,000 of the population, were—Plymouth 13, Birmingham 15, Brighton 16, Bristol 17, Wolverhampton 17, Hull 17, Bradford 18, Edinburgh 19, Glasgow 19, Norwich 19, Salford 19, London 19, Newcastle-on-Tyne 20, Sunderland 20, Leeds 20, Portsmouth 20, Nottingham 20, Leicester 21, Manchester 22, Sheffield 22, Oldham 22, Liverpool 24.

THE Royal Commission on the Medical Acts met on Friday, Saturday, and Monday, 27th, 28th, and 30th of May, at 2 Victoria Street, Westminster, London. There were present the Earl of Camperdown (chairman), the Right Hon. W. H. F. Cogan, the Master of the Rolls, Sir William Jenner, Mr. Simon, C.B., Professor Huxley, Dr. M'Donnell, Professor Turner, Mr. Bryce, M.P., and Mr. John White (secretary). The evidence of Dr. Acland, Sir James Paget, and Mr. Erichsen was taken.

IN the principal foreign cities the rates of mortality, according to the latest official weekly return, were in—

22; Brussels 22; Amsterdam 23, Rotterdam 19; The Hague 24; Copenhagen 29, Stockholm 26, Christiania 21; St. Petersburg 62; Berlin 23, Hamburg 24, Dresden 27, Breslau 29, Munich 39; Vienna 32; Buda-Pesth 38; Rome 29, Naples 33, Turin 26; Alexandria 36; New York 33, Brooklyn, 24, Philadelphia, 23, Baltimore, 23 per 1,000 of the various population.

## Scotland.

(FROM OUR NORTHERN CORRESPONDENT.)

GLASGOW WESTERN INFIRMARY.—The new wing of the Glasgow Western Infirmary, added through the bequest of the late John Freeland, a native of Glasgow, who died at Nice, leaving £40,000 for this purpose, was publicly opened on the 1st inst. The additional wing is on the east side of the building, and contains about 200 beds, which just doubles the accommodation of the infirmary. The new wards have been arranged and fitted up with all skill and care, and their bright airy appearance very much impress a visitor. A building for the accommodation of the nurses has also been added. The proceedings were conducted in the clinical theatre, and there was a large attendance of ladies and gentlemen.

GLASGOW ROYAL INFIRMARY APPOINTMENT.—Dr. John Barlow, Lecturer on Physiology at Anderson's College, has been appointed Extra-Surgeon to the Royal Infirmary Dispensary. The other candidates were Drs. Kirk, Muir, and T. B. Henderson.

GLASGOW MATERNITY HOSPITAL.—Dr. Hugh Miller has issued in a separate form his introductory lecture of the clinical course at this Hospital for 1881. Introductory addresses are a species of literature *sui generis*, and must not be tried by the recognised canons of taste, either in respect of matter or style. While we do not agree with Dr. Miller's medical philosophy, nor admire altogether his somewhat reckless use of metaphor, we doubt not that in proper hands both instruction and information will be derived from this address. The history of the obstetric art is traced from the time of Hippocrates (*Hypocrates*, of a former distinguished Glasgow obstetrician) down to the present time, and an exposition given of the conflicting theories of disease, and the improvement made in mechanical appliances. We do not find that Dr. W. L. Reid's forceps has been referred to, or the nebulous carbolic reception of the new-born babe. Surely this is an overlook. By the bye, was *Dioscorides* a Glasgow obstetrician?

GLASGOW DEATH-RATE.—The death-rate of Glasgow for the week ending with Saturday, the 28th ult., was 22 per 1,000 per annum.

HEALTH OF EDINBURGH.—For the week ending with Saturday, the 28th ult., the deaths in Edinburgh numbered 80, and the death-rate 18 per 1,000. Chest diseases still account for half of the mortality, while that from zymotic diseases amounts to 11.

COMBE LECTURES.—On the 31st ult. the fifth of the series of Combe lectures was delivered by Dr. Andrew Wilson in the hall of the Church of Scotland Training College, Chambers Street, Edinburgh. There was a large attendance of students and others. Dealing in the outset with the subject of joints, the lecturer remarked that these were divisible into two great groups—incomplete and complete joints. The three chief

kinds of joints found in the body were hinge joints (three-fourths of the whole being of this description), ball and socket joints, and pivot joints. The lecturer illustrated the structure of these and the muscle of the arm by means of a beautiful model prepared for the Combe trustees, and went on to describe the functions of the body in action. He pointed out that food, however nourishing, was totally incapable of sustaining life in the absence of water, and in this connection observed that if the public had been better informed on the subject less surprise would have been expressed at the "fasting" experiment of Dr. Tanner, which taught nothing that was new. There were cases on record of life being prolonged for fifty and fifty-five days on water, so that there was no mystery about the matter. In closing Dr. Wilson touched on the question of diet, which, he explained, should be regulated by the following circumstances:—Personal constitution, age, habit, and occupation, state of health, and race or climate.

**REGISTRAR-GENERAL'S RETURNS.**—The weekly return of births, deaths, and marriages in the eight principal towns of Scotland for the week ending Saturday last, says:—The death-rate in the eight principal towns during the week ending with Saturday, the 28th May, 1881, was 18·4 per 1,000 of estimated population. This rate is 5·3 under that for the corresponding week of last year, and 1·5 under that for the previous week of the present year. The lowest mortality was recorded in Dundee, viz., 11·4 per 1,000; and the highest in Perth, viz., 29·2 per 1,000. The mortality from the seven most familiar zymotic diseases was at the rate of 2·8 per 1,000, or 0·4 under the rate for last week. Acute diseases of the chest caused 89 deaths, or 7 less than the number recorded last week. The mean temperature was 54·9, being 5·9 above that of the week immediately preceding, and 1·3 above that of the corresponding week of 1880.

**EDINBURGH INFIRMARY FEVER HOSPITAL.**—Under the warrant granted on Thursday, the 2nd inst., by the Edinburgh Dean of Guild Court, operations were commenced yesterday, at the instance of the managers of the Edinburgh Royal Infirmary, for the conversion of the eastern division of the old Infirmary buildings into a fever hospital for the reception of patients who, but for the terms of the Infirmary charter, would fall to be treated in the new buildings in Lauriston. By a rearrangement of the wards, provision is to be made for seventy-four beds, which will be set apart for the treatment of cases of typhus fever, typhoid fever, erysipelas, and small-pox. The sanitary arrangements of the hospital will be improved in accordance with modern requirements, and suitable accommodation provided for the nurses who are to reside within the building, while a small lodge is to be built for the gate porter. The alterations are expected to be completed by the end of October, at a cost of about £2,500. Messrs. D. & J. Bryce, 131 George Street, are the architects for the work. As has been previously mentioned, the remaining portions of the old Infirmary buildings have been acquired by the Town Council for the purpose of being fitted up as a general hospital for the treatment of infectious diseases.

## Literature.

### SYPHILIS AND MARRIAGE. (a)

THIS is a welcome volume, inasmuch as it may, for the first time, introduce to English readers, in their own tongue, one

(a) "Syphilis and Marriage." By Dr. Alfred Fournier. Translated by A. Lingard, with a preface by Jonathan Hutchinson. London: Bogue. Pp. 264. 1881.

of the numerous treatises of the first of modern writers on syphilis, Dr. Alfred Fournier, Professor of Syphilography at the Ecole de Médecine, of Paris. The work is sure to be widely read, since it has been graced by a preface from the most ingenious of all English writers on the disease, Mr. J. Hutchinson.

A pupil of Ricord, M. Fournier has been the friend and coadjutor of that eminent Parisian surgeon for the last twenty-five years, ever since the period when Bassereau made the important discovery that there was no connection between soft sores and the initial lesion of syphilis (the hard sore), and, at the same time, showed that secondary symptoms were contagious, and, indeed, by far the most common causes of contagion in the disease. Dr. A. Fournier, in his splendid monographs on the chancre, on gonorrhoea, on tertiary syphilis, on syphilis in women, on the incubation of the syphilitic chancre, and a perfect host of other subjects relating to venereal diseases, has proved himself to be by far the most learned and competent writer on that branch of medicine.

In this treatise, on the question of syphilis in marriage, Mr. Fournier is justly anxious that such a formidable disease shall not be allowed to contaminate in any great degree the fountain-head of future generation, the married state.

As Mr. Hutchinson remarks, he is very familiar with facts as to the long and almost indefinite persistence of the syphilitic taint when imperfectly treated; and of the lamentable consequences of rash and unauthorised marriage under such circumstances. Not only, as he is careful to remind us, have these consequences concerned the health of wife and child, but occasionally, by the permanent incapacitation of the husband, the family has been plunged into deep poverty. So strong has been the impression which facts of this kind have made upon his mind, that he has been driven to conclusions, which may appear to others, less conversant with them, to partake of an alarmist character.

In this country it has been considered sufficient to keep a man from marrying until he has passed some two years or so after contracting the primary sore. As far as we remember, Mr. Lawrence used to recommend a man to put off his marriage day only for a year, and his pupil, Mr. Jonathan Hutchinson recommended a delay of two years.

Mr. Alfred Fournier is far more exacting than any English authority has deemed it necessary to be. After quoting from some medical men who think that a man who has once contracted the disease ought never to become a father, and refusing to go so far as that, he says (p. 101):—

"Not to take into account for the moment any other point than the length of time during which the patient has been contaminated, I do not believe that a syphilitic patient should be permitted to dream of marriage under a minimum of four years, devoted incessantly to treatment. Three or four years, such is, according to my view, the minimum (note well the word, if you please) the necessary indispensable minimum, in order that the diathesis may sufficiently disappear under the double influence of time and treatment, and that the patient, again returning to health, may have the right to aspire to the titles of husband, father, and head of a family. Yes, three or four years; and it is not too much. I am not too exacting. A longer time would be even better, I am certain; for with syphilis it is always well to wait when it involves interests so sacred as those of a young wife and a whole family."

After three or four years have passed usefully devoted to a proper treatment, I think myself authorised by experience in tolerating the marriage, excepting on account of some particular contra-indications, deducible from one or other condition of the programme."

Another case is as follows:—A syphilitic man marries, and may or does infect his wife. What is to be advised? Dr. Fournier replies as follows (p. 168):—"As regards the husband there can be no doubt there is nothing else to be done than to prescribe a treatment, and clearly and unmistakably to intimate to him that *he must not become a father*. You know, gentlemen, what happens in a pregnancy when both parents are infected; above all, when maternal syphilis is recent, and has not yet undergone the corrective influence of treatment. Pregnancy, under these circumstances is a disaster. It is your duty, then, to instruct your patient upon this point, and in order to leave no doubt upon his mind you must speak as follows:—"In your present condition, in the disease which affects both you and your wife, pregnancy would be the greatest possible misfortune, for your child would either die before birth, or else it would come into the world with syphilis, to the great trouble both of yourself, your wife, and

your two families, not to mention the gossip of your friends, &c.'" On page 161 he adds—"So listen to me attentively: you must take every care not to have a child." You are free, gentlemen, to enlarge upon this subject, and to complement your meaning by such instructions as your client may require. You are free, as M. Diday says, to be the professor to the end, but whilst keeping within the bounds of decorum, let not your meaning be doubtful."

Dr. Fournier considers that no patient who has once been affected by any cerebral symptom of a syphilitic kind ought to think of marrying; and as he seems to be of the opinion that benignant eruptions are oftener followed by such brain affections than the severer forms of eruption, he would seem to hint that when the disease is very mild at the commencement the patient ought to defer for very many years all thoughts of paternity.

Infantile syphilis, according to Fournier, is a most fatal disease. His hospital notes show that in 167 cases of pregnant syphilitic women the child survived only 22 times, whilst there were 145 cases of the death of the child through miscarriage, premature birth, still birth, or early death after birth. Dr. Coffin at the same hospital, Lourcine, noted only one surviving child out of 28 pregnancies among his patients, and Dr. Pileur found that of 260 children born living at full term, 141 died in a very short time, and only 22 survived more than a month.

With regard to treatment, Fournier is a well-known mercurialist of the most pronounced order. He prescribes the drug by a method which he styles *successive and intermittent*, which consists in giving about two grains daily of proto-iodide of mercury for about a couple of months, then omitting a month, then returning to the dose for about two years. Then, after this, the patient who is a candidate for marriage and paternity is to have more treatment, mercury and iodide of potassium. In page 184 he thus speaks:—"For my part, I believe myself authorised to say, from what I have seen, that in no case the duration of anti-syphilitic treatment should be less than three or four years, whatever may be the form of the disease, and however mild originally. Three or four years methodically consecrated to an energetic medication, such is the necessary minimum, according to my view—I will not say to cure the disease, but to suppress its dangerous manifestations for the present and for the future." What will the medical world say to this in London?

## Correspondence.

### NEW SCHEME OF EDUCATION AND EXAMINATION OF THE ROYAL COLLEGE OF SURGEONS IN IRELAND.

[Although the Fellows of the College have, at their general meeting last Saturday, decided to approve of the Scheme being brought into operation, which decision has made the publication of this letter unnecessary, nevertheless, we think it well to print it, as it goes far to confirm the Fellows in the determination at which they have arrived.—Ed. M. P. & C.]

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I beg you will allow me to give some explanation as to the details of the proposed Scheme. I have already shown that the institution of sessional examinations is the essential part of the Scheme. For the efficient working of this it is obvious that the examinations must be honestly sessional, that there must be no over-lapping, no crowding together of all the examinations. The student must prove at the end of each year that he has done the work of the year, and that he is prepared to advance to the higher range of subjects, having mastered the lower. It is therefore made an absolute rule that each year's examination must be passed before credit be given for further studies, except in cases of illness, or when, from other causes the student is unable to comply with the rule, when the Council may, on special application permit him to present himself for examination after the succeeding year of study has been entered upon. Two opportunities are provided for him each year—one in July, immediately after the termination of the year's studies, the other three months further on, so if he fail in the first in-

stance he can try it again. It has been objected that the making it imperative that each year's examination should be passed within the year will, in case of rejection, impose an additional year of study. But if a student should be so idle or so incompetent that he could not go through an examination in a limited range of subjects, at the end of a year devoted to their study, it is better that this should be discovered promptly, than that he should go on to the end of the course wasting his time and money by erroneous methods of study, or indulgence in idle and vicious habits, and that if he be unfit for his profession he may learn it in time and apply himself to other pursuits.

The first year of professional study is arranged so that the student may, if the son or pupil of a medical man, pursue his studies at home under the eye of his parents. The physics, elements of chemistry, and botany are taught in the better class of schools, and even in the model schools under the National Board, or they can be studied still better under the supervision of educated medical men, by the aid of some of the excellent manuals now so easy of access. For five or ten pounds all the apparatus and materials for their practical study may be obtained. An hour or two spent each day in the compounding department of a workhouse hospital or dispensary would teach all the pharmacy required. A box of bones and a cheap microscope would complete the equipment. The student who could slice a potato and demonstrate its structure in a microscope, and recognise the vessels and fibres in a stalk, would be well prepared to enter on the study of structural anatomy. The careful observations of minute details involved in the correct description and classification of a few familiar plants would be the best preparation for higher studies. At the same time a familiarity with the outward aspect of discourse and the daily routine of practice may be acquired in the hospital or dispensary. In this way a student would soon come to know whether the profession he has chosen is one suited to his taste and abilities. He would acquire an amount of elementary knowledge and manipulative skill that would enable him to at once take advantage of the systematic teaching of the lecture theatre and dissecting room, and when visiting a clinical hospital, instead of being shocked by what he sees, and puzzled by the virtually unknown language he hears, he would be able from the commencement to appreciate and store up for future use the information afforded him. A not less important feature of this system is the experience of life and opportunity of forming character and educated tastes so obtained. Instead of a lad, fresh from school and freed for the first time from the restraints of school life being sent to live in chambers in a large city, and exposed not only to the temptations of a city life, but it may be, to the evil example and influence of class fellows who have already fallen, he may pursue his studies for this year at home, under home influences and home supervision, and be prepared to enter on the battle of life with a more matured experience of its dangers and realities, and with associations, habits, and tastes to make him a less easy victim to temptation.

Those students who may have it in their power to attend lectures on practical anatomy and chemistry at this period are recommended, but not required to do so, partly for the benefits to be derived from the lectures, and, still more, that they may have more time in future years to devote to clinical and practical work.

After the first year the remaining studies must be pursued in the school and the clinical hospital, and the curriculum is arranged so as to allow of the fourth year being almost entirely devoted to the hospital work and the study of disease, as well as the greater part of the third—and for the fourth or final examination the student is afforded three opportunities of passing, at one or all of which he may present himself.

That "this system is in theory good" is admitted by the most earnest opponents of its adoption. That it is calculated to improve the education of our students, to raise the status of our profession, to serve the interests of society, and thus enable our College to promote its reputation, to maintain its honour and dignity, and most efficiently fulfil the objects for which it was instituted, and that it should therefore be adopted and enforced is held by a majority of the Council numbering at least two to one—a majority embracing some of the most sagacious, most experienced, and most cautious men who at present take part in the management of the College. But it is said—"This measure will imperil the existence of the College." There are some men who see ruin in every reform, but the reform comes, and cannot be stopped, and bring not

ruin, but renewed vigour and increased prosperity. Such, I believe, will be the result of the adoption of the present proposal. At all events, it is our duty to do that which we believe to be right, let the consequences be what they may.

I am, Sir, yours, &c.,

GEORGE H. KIDD.

28th May, 1881.

### ANIMAL VACCINATION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—As it seems that the preliminary objections to animal vaccination have now been overcome, and we are even promised that, in some indefinite future, calf lymph shall be supplied from Government sources, for the keeping up of stocks, may perhaps eventually, to be of use to us in times like these, when small-pox is so common in London, and lymph is obtained with such difficulty, perhaps it would be as well to remember what experience has already taught with regard to the origin and properties of cow-pox.

*Origin.*—First of all, then, it appears from the wide experience of Mr. H. Martin, of Boston, that it is not sufficient for the purposes of obtaining lymph of good quality, to take vaccine lymph from the arm of an infant, and therewith raise vesicles on a calf. It is true, that this so called *retro-vaccination* succeeds perfectly in causing the appearance of vesicles on the animal; but the lymph thus produced, was found to be quite destitute of protection power (Martin's pamphlet, 1876).

Again, it is unwise to repeat the experiment of Coely and Badcock, and to inoculate calves with the pus from small-pox patients, because it has been found (Chauveau) that *occasionally*, when infants have been vaccinated from the eruption caused on the animals by those inoculations, small-pox has been produced. There is, however, no necessity to do this any longer, since there are so many sources of undeniable cow-pox in Europe and America at present, whence calves may be inoculated without such risk.

At the same time, notwithstanding the negative results of the attempts of Chauveau Viennois and Meynet at Lyons, when they attempted to inoculate cows with variola, and failed to obtain any well marked vaccine vesicle, I have become convinced from a long personal conversation at Cambridge with the late Mr. Coely himself, in August, 1880, that small-pox in the human being is the real origin of vaccinia. In what way the transformation takes place in the organism of the bovine species, I leave those to determine who can better judge of the varieties of microscopic elements and their affinities. But, as far as evidence goes at present, it seems to me, proved that vaccinia is modified variola.

I notice from time to time that practitioners complain of the failure of the calf lymph contained on points to produce any effect. This is due to the cause which makes human lymph on points also often fail. But now where, as in London, we have such an excellent operator as Dr. Renner to betake ourselves to, to get *perfectly fresh lymph*, such failures are indeed rare. I would recommend all London practitioners to go to the calf itself, at 28 Marylebone Road, and see that they get the lymph fresh from the animal, and then they will no longer have to complain of its insufficiency.

I am, Sir,

Yours obediently,

C. R. DRYSDALE, M.D.

17 Woburn Place, W.C.  
May 27, 1881.

### IRISH MEDICAL ASSOCIATION.

THE annual meeting of this Association took place on Monday, at the Royal College of Surgeons in Ireland, and attracted an unusual number of members. The day's proceedings were inaugurated by a breakfast at the Shelburne Hotel, to which the Association was invited by Dr. McClintock, the President of the College of Surgeons. Nearly 100 members sat down, and they were welcomed in a short speech by the host, and after the re-

past Dr. Chapman, President of the Association, returned the thanks of the members for the hospitality extended to them.

The meeting for despatch of business opened a little after 12 o'clock, Dr. Chapman occupying the chair. After some discussion on a personal matter, the report was read and its adoption moved, to which proposal an amendment to omit a paragraph relating to defaulters, was moved by Dr. Chaplin. This proposal was negatived, and there followed a most interesting and prolonged debate on the policy of the Association with reference to the Infectious Diseases Bill. An amendment to the report to omit those paragraphs which pledge the Association to oppose the Bill was moved by Dr. Robert MacDonnell and seconded by Dr. J. W. Moore. This proposal was supported by Dr. Cameron, Dr. McClintock, Mr. Stokes, and Dr. Corley, and was opposed by Drs. Jacob, Quinlan, Darby, Jones (Cork), Welsh, Martin (Portlaw), Jacob (Maryboro'), Davys (Swords), and other speakers. The debate lasted over two hours, and a division resulted in the rejection of the amendment and affirmation of the policy of the Association by 23 to 11.

Several other important resolutions were adopted. We shall give a full report of the proceedings next week.

### THE ELECTION AT THE IRISH COLLEGE OF SURGEONS.

THE election of President, Vice-President, and Council took place on Monday last. New, and apparently very satisfactory, arrangements had been made to discourage canvassing within the walls of the College, and to enable voters to mark their lists without being overlooked. The entire outgoing Council offered themselves for re-election, and in addition, Mr. Baker, Drs. Bennett, Roe, Meldon, and Franks presented themselves to the electors. One-hundred-and-six Fellows voted, and the result of a scrutiny showed that all the Council retained office, save Mr. Alcock Nixon—Dr. H. Bennett, Professor of Surgery in the School of Physic being elected. Dr. Chaplin, of Kildare, the outgoing Vice-President, succeeded to the Presidency; and Dr. John Kellock Barton, Surgeon to the Adelaide Hospital, was chosen Vice-President.

Royal College of Surgeons of England.—The following candidates, having passed the required examination for the diploma, were admitted Members of the College on May 18th :—

Dixon, George Frederick	Rowley, Charles
Jones, William Wansborough	Shore, Herbert George
Owen, John Morgan	Tripp, Charles L. H.
Rigby, John, L.S.A.	Wood, Louis Edmund

The following were admitted Members on May 19th :—

Anderton, James Edwin	Laurent, O. A. Eugene
Boerwell, John Irvine	Mudge, Thomas
Buxton, Joseph Wilmot	Medley, Harold T. D.
Cranston, William Lefevre, L.S.A.	Slater, William
Evans, Thomas G. C.	Tew, James Scott, L.S.A.
Heyman, Frank Gibbins	Udale, Joseph James

Examinations for the F.R.C.S. Eng.—The following gentlemen passed the first part of the professional examination for the Fellowship at meetings of the Board of Examiners on May 21st, 23rd, 24th, and 25th :—

W. S. A. Griffith, A. Dingley, Alfred J. Anderson, E. R. Williams, Edmund W. Roughton, and Frederick J. Paley, St. Bartholomew's Hospital; G. S. Watson and M. H. Bulteel, St. George's Hospital; W. Willis, Glasgow, Edinburgh, and Middlesex Hospital; Joseph Cullier and Alexander Wilson, Owens College, Manchester; A. Q.

Silcock, University College; Ernest E. Maddox, Edinburgh; Walter R. Wynter, Middlesex Hospital; Sidney Worthington and Wheelton Hind, Guy's Hospital; Charles A. Ballance, St. Thomas's Hospital; Henry W. Pigeon, Cambridge and Guy's Hospital; John C. Davie, London Hospital; John Y. Bostock, Cambridge; Herbert H. Ashdown, Edinburgh; D'Arcy A. Power, Oxon and St. Bartholomew's Hospital; William H. Horrocks, Liverpool and University College; Charles A. Morris, Cambridge; J. Donald, Charing Cross Hospital; Ernest Hudson, University College; Charles H. Wise, Queen's College, Galway, and Westminster Hospital; Walter T. Brooks, King's College; Edward Harrison, Cambridge; Louis A. Dunn, Guy's Hospital; David L. Jones, Charing Cross Hospital; and Joseph L. Hewer, St. Bartholomew's Hospital.

## NOTICES TO CORRESPONDENTS.

**CORRESPONDENTS** requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

**MR. E. T. SANDERS.**—We have no objection to tell you all we know about the matter; and concerning the point of interestedness we must leave you to form your own conclusions. Of course it is impossible for us to make the subject one for public comment, though it would please us well to do so. Tied as we must be, therefore, we can only wait until the time for definite action arrives.

**A COUNTRY SURGEON.**—Consult Gant's "Science and Practice of Surgery" and Holmes' "System." The treatment, we consider, should be specific, though not a few surgeons regard the growths as warty excrescences merely. Calomel, in the form of a powder, applied to the surfaces has yielded good results with us frequently; but it is necessary to keep the masses carefully separated by lint or cotton wool. Mutual pressure encourages discharges and retards healing. The size need not alarm you at all. It is very common to see them here at least twice as considerable. Subscription duly received and handed to publishers, who will forward receipt.

**CAUTION.**—There has been no second edition, but we are informed the first is all but exhausted, and will shortly be followed by another. The work includes directions for staining and mounting specimens, as well as for preparing and hardening them. Its full title is "Manual for the Physiological Laboratory."

**MR. GRINDROD.**—You are quite right. We shall be glad if you will call, when it shall be fully explained.

**A STUDENT.**—You are by no means alone in complaining of the treatment you were subjected to, and we have it under contemplation to recommend a lengthy inquiry into the conduct of the persons you name. It is most unfortunate that those occupying so important a post, a post, too, in which urbanity, good feeling, and the utmost consideration are demanded, should constantly exhibit such wanton disregard of all canons of good taste and good breeding as has been continually done by the two examiners you mention.

**A SUFFERER.**—See reply to "Student." We may add that the greatest indignation has been called forth in several quarters by the repeated acts of terrorism you complain to have been subjected to, and probably it will result in important changes.

**THE INTERNATIONAL MEDICAL CONGRESS.**—The Hon. Secretary General appeals in our advertising columns to intending subscribers to remit their subscriptions without further delay. He will be also glad if all who can make it convenient will call at the Royal College of Physicians and register their names.

**MR. SIDNEY DAVIES** is thanked for report of case, which shall appear in an early number.

**MR. COATES.**—See reply to Mr. Sidney Davies.

**THE NEWSPAPER PRESS FUND.**—The anniversary dinner of this Fund, which is fixed to take place at Willis's Rooms on Saturday, the 18th inst., under the presidency of the Right Hon. Sir Stafford Northcote, M.P., promises to equal in its attractions and results the most successful of the previous festivals. The list of stewards, containing about 220 names, includes distinguished members of the Corps Diplomatiques, members of both Houses of Parliament, and other gentlemen eminent in art, literature, and science, and the liberal professions. Mr. Sims Reeves hopes to be able to assist in the musical programme, which, it is anticipated, will, as heretofore, be under the direction of Sir Julius Benedict.

**DR. C. J. P.**—We believe it to be a legally constituted institution, but have no personal knowledge of the governing body.

**VACCINATOR.**—Opinions are very divided as to the quality and efficacy of the lymph supplied from the National Vaccine Establishment. We have good reason to believe that failure in some cases is the result of a careless performance of the operation.

**F.R.C.S.**—His term of office as president has expired.

**DR. J. E. R.** should read Dr. Richardson's article afresh; it should be taken in the light of an inquiry, not as dogmatic teaching. The author's experience is decidedly valuable.

**QUACK NOSTRUMS.**—A correspondent in Scarborough remarks that the letter signed "A Physician" in our last is only too true. He instances a case within his own personal knowledge where a man who could not earn sufficient by blacking boots became an itinerant quack medicine-vendor. At this he became rich enough to educate his son for the profession, and died worth a fortune. The son, although a member of the Royal College of Surgeons of England, would not stoop to practice, but lives in luxury upon a few quack medicines, one of which is advertised to cure seventy-nine different diseases and ailments. He thinks that cases of this kind are not encouraging to honourable conduct, and complains of the connivance of the Government in making revenue from the sale of patent medicine stamps.

**CONSULTATION WITH HOMOEOPATHS.**—Referring to the Quain-Kidd controversy, the *Cincinnati Clinic* sums it up thus: "A physician cannot consult with a homoeopath for two reasons—1, because he is a homoeopath; and 2, because he is not."

## VACANCIES.

**Brookwood Asylum, Surrey.**—Temporary Assistant Medical Officer. Salary, two guineas per week and board. Applications to Dr. Brushfield at the Asylum, Woking, Surrey.  
**City Provident Dispensary.**—Assistant Surgeon. Salary, £120, with extras for midwifery. Applications to the Secretary, 164 Aldersgate Street, London, E.C., before June 15.  
**Sheffield Union.**—Resident Assistant Medical Officer. Salary, £100, with board. Immediate applications to the Clerk to the Guardians, Union Offices, Sheffield.  
**Stirling District Asylum, Larbert.**—Assistant Physician. Salary commencing at £80, with board. Applications to Dr. MacIaren before June 11.  
**Marlybone Western General Dispensary.**—Physician. Honorary. Applications to the Secretary before June 13.  
**West Riding Asylum, Wakefield.**—Resident Clinical Assistant. Board, but no salary attached. Applications to Dr. Herbert Major at the Asylum.

## APPOINTMENTS.

**ADAMS, M. A., F.C.S.**, has been re-appointed Public Analyst for the Borough of Hythe.  
**BAKER, J. B., L.R.C.P., M.R.C.S.E.**, House Physician to Charing Cross Hospital.  
**BENHAM, F. L., M.R.C.S.E., M.B., B.S.**, Assistant Medical Officer to the New Infirmary, St. Marylebone.  
**CANNING, P. W. G., E.N., L.R.C.P., Ed., L.R.C.S.Ed.**, Resident House Surgeon to the Hull and Sculcoate Dispensary.  
**CARTER, R. B., F.R.C.S.E.**, Ophthalmic Surgeon to the Bolingbroke House Hospital for Paying Patients, Wandsworth.  
**FRASER, T., M.B., L.R.C.P., Ed.**, Medical Officer to the Workhouse of the Berwick-on-Tweed Union.  
**GORDON, S. M.D.**, Consulting Physician to the Coombe Lying-in Hospital, Dublin.  
**GUNN, R. M., M.A., M.B., C.M., M.R.C.S.E.**, Ophthalmic Surgeon to the North-West London Free Dispensary for Children.  
**HADDEN, W. B., M.D., M.R.C.S.E.**, Physician to the St. George's and St. James's Dispensary.  
**HALL, S., M.B., M.R.C.P.**, Assistant Physician to the Metropolitan Free Hospital.  
**JULER, H. E., M.B., F.R.C.S.E.**, Assistant Surgeon to the Royal Westminster Ophthalmic Hospital.  
**KILNER, C. S., M.B., C.M.**, Medical Officer to the Workhouse of the Thingoe Union.  
**LUNN, J. R., M.R.C.S.E., L.R.C.P.**, Principal Medical Officer to the New Infirmary, St. Marylebone.  
**LYSTER, Mr. C. R. C.**, Assistant House Physician to Charing Cross Hospital.  
**MIDDLETON, W. H., L.K.Q.C.P.I., L.R.C.S.I.**, Visiting and Consulting Physician to the Mullingar Lunatic Asylum.  
**MORGAN, W. L., M.A., M.R.C.S.E.**, Surgeon to the Radcliffe Infirmary, Oxford.  
**MOSSE, Mr. H. E.**, Assistant House Surgeon to Charing Cross Hospital.  
**NANCE, Mr. H. C.**, House Surgeon to the Whitehaven and West Cumberland Infirmary and Fever Hospital.  
**NOAKES, S. S., L.R.C.P.L., M.R.C.S.E.**, Temporary Assistant Medical Officer to the County Asylum, Lancaster.  
**OLIVER, J., M.B., C.M.**, House Surgeon to the Durham County Hospital.  
**WOODHEAD, G. S., M.B., M.R.C.P. Ed.**, Demonstrator of Pathology and Assistant to the Professor of Pathology, University of Edinburgh.

## Births.

**BERRY.**—June 3, at Appleton Cottage, Great George Street, Wigae, the wife of William Berry, M.R.C.S. Eng. & L.R.C.P. & S. Ed., of a daughter.  
**CHURCHILL.**—June 1, at 4 Cranley Gardens, South Kensington, the wife of Frederick Churchill, M.D., F.R.C.S., of a son.

## Marriages.

**THOMPSON-KNIGHT.**—March 23, at St. John's Church, Belfast, Victoria, William Brendon Thompson, second son of Dr. John Thompson, F.R.C.S., of Bideford, North Devon, to Jessie Maude, eldest daughter of the late James Mylne Knight, Esq., of Rosebrook, Victoria, formerly of Edinburgh.  
**WILLIAMS-BURTON.**—June 1, at the Abbey Church, Selby, Yorks, H. J. Carnegie Williams, Esq., of Santa Fe de Bogata, U.S., of Colombia, eldest son of H. Lewellyn Williams, M.D., of 5 Atherton Terrace, Queen's Gate, S.W., to Rose Matilda, eldest daughter of J. Burton, Esq., of Turnham Hall, near Selby.

## Deaths.

**DENNIS.**—June 1, at Burnham, Westgate, Norfolk, Augustine Valentine Dennis, M.R.C.S.E., aged 63.  
**HILLIARD.**—May 21, at the Vicarage, Tettenhall, near Wolverhampton, G. R. Hilliard, M.R.C.P.L., late of Chelmsford, aged 80.  
**NAPIER.**—May 20, suddenly, at George Street, Hanover Square, London, W., W. Donald Napier, M.R.C.S.E., aged 50.  
**RADFORD.**—May 29, at Higher Broughton, Thomas Radford, M.D., F.R.C.P. Ed., aged 88.  
**ROWAN.**—At his residence, West End, Kilkee, Dr. Rowan, aged 32.  
**WHITLEY.**—May 20, at Bedlington Vicarage, George Whitley, M.D., aged 65.

### CLINICAL LECTURE

#### ON THE DIFFERENTIAL DIAGNOSIS BETWEEN CERTAIN HYSTERICAL CONDITIONS AND MYELITIS.

Delivered at the National Hospital for the Paralyzed and Epileptic.

By THOMAS BUZZARD, M.D., F.R.C.P.

(Continued from page 441.)

GENTLEMEN,—In the diagrams before us (drawn from photographs for which I am indebted to Dr. Gowers) are two pairs of feet which present a certain superficial resemblance. In each the inner border is drawn up into the position of a not severe varus. They are the feet of two young women who were in the hospital at the same time, and there is this especial point of interest about them, that F—, really a case of acute myelitis, had been treated as a case of hysteria; and B—, really a case of hysteria, came in as a paralytic.

F.

I show you the patient F—. She came into the hospital on April 24th, 1880, on account of loss of power in the

lower extremities. The girl is the daughter of a labourer, and she has always lived well. Her parents are both alive and healthy. Two of her brothers have died "in fits," one at four years, the other at fifteen years of age. I record this circumstance, but it is really valueless. So-called fits may mean almost any kind of sudden seizure, whether attended by loss of consciousness, or convulsions, or not. The patient herself has never suffered from scarlatina, acute rheumatism, or chorea. The history of her present illness is this: On December 30th, 1879, she suddenly complained of a feeling of pins and needles in both lower extremities, from the waist downwards, and this continued for a whole day. Next morning she managed to get downstairs, but suffered such great pain in her legs that she returned to bed. In the evening she again got up, and was able at that time to walk with help. The next morning, however, she could not move her legs at all, and could not feel when they were touched. There was no pain or constrictive feeling in the waist. She had felt perfectly well the day before the illness began, had not had any shivering, and had not, to her knowledge, taken cold. About a week previously remembers to have had a little pain in the back of her head, and on the morning of the attack she felt giddy. For a week after the attack she was feverish, and very thirsty and restless. She could not sleep at night. It appears, too, that for some

B.

time after her attack there was retention of urine, and a catheter was used. Later on there appears to have been

some incontinence of urine, as well as loss of control over the bowels, and some not severe bed-sores. Two months after the onset she, for the first time, began to move the left leg. The right leg was not able to be moved till five weeks later. She recovered sensation in the left leg about six weeks after the onset, and in the right about a week afterwards.

The following note of the patient's state was taken by Dr. Broster on admission. She is a fairly nourished girl, not manifestly anæmic, but her hands are cold and cyanotic, the lips being natural. She feels quite well in herself, has no headache, and sleeps well. There is no paralysis of the face or upper limbs. The spine presents no curvature, and is free from pain and tenderness. She has no feeling of a tight band about the body. The lower limbs both look blue and are cold, especially about the feet. The left leg in the lower part of the calf measures ten inches, the right eleven. The left thigh measures thirteen inches, the right twelve. She can lift the left heel two feet off the bed, and can bend the left knee. On the right side, on the other hand, she can only just make the faintest attempt at flexing the hip-joint or ankle-joint, and cannot flex the knee-joint at all. The left foot is not distorted, but the right foot is in a position of talipes varus; it can be everted by external aid, though not by the patient's volition. The foot cannot, however, be extended forcibly. If an effort be made to do this, the tibialis anticus becomes quite tight. There is no rigidity of the joints. The patellar tendon reflex is absent on the right side, and notably deficient on the left. There is no ankle clonus on either side. The cutaneous reflex from the sole of the right foot is absent altogether, and is only slight in the left.

When admitted, the muscles of the left leg reacted to induced currents of a little greater strength than those capable of causing the contraction of healthy muscle. On the right side, however, whilst the anterior tibial group of muscles required considerably stronger currents than in health, the peronei did not reach to the greatest strength of Stohrer's battery. The cutaneous sensibility did not appear to be defective in either leg. The action of the bladder as well as that of the rectum was normal. The catamenia had never been established.

After a week the following result was obtained from electrical examination:—

*Right Side (Faradism).*—In the vastus internus (motor point) no reaction was obtained. The tibialis anticus muscle responded nearly normally. The peroneus longus did not react to the strongest current which the machine could give.

*Left Side.*—The vastus internus (motor point) required a current of 10 deg. (in the machine employed 20 deg. is the weakest strength, 15 deg. that required normally). The anterior tibial group of the peronei required 12 deg.

On May 6th the patient found that she could lift her right heel about two inches off the bed, and just flex her right ankle-joint slightly, but she could not bend the right knee. Examined by the voltaic current (galvanism), both left and right anterior tibial group reacted to the interruption of a current from 22 cells Stohrer. The left quadriceps extensor responded to 30 cells, but in the right no contraction could be produced by any strength employed.

May 12th.—She can raise the left heel a yard off the bed and the right about six inches. The right ankle-joint can be moved better. She can now just bend the right knee.

November 2nd.—She is able to walk on crutches, the right foot being dragged. As she stands she can move the right lower limb forwards and backwards, and lift the knee from the ground by the iliaco-psoas.

*Electrical Examination.*—Right leg. (Faradism.) Tibialis anticus is nearly normal. Extensors of the toes and big toe and peroneus longus no reaction. Quadriceps extensor no reaction to galvanism. Peroneus longus 20-30 cells slowly interrupted, slight reaction. Vastus externus reacts to 30 cells. Vastus internus shows no reaction.

Nov. 23rd.—Right leg. (Galvanism.) The vastus internus now reacts to 16 cells interrupted, the externus to 20 cells, the peroneus longus to 28 cells. There is still no patellar tendon reflex in the right limb; it is present in the left.

This girl, who was taken ill on Dec. 30th, 1879, went to an hospital on Jan. 9, having at that time entirely lost the use of both lower extremities. She was at once treated with a daily cold shower bath, and after a week currents from a magneto-electric machine were applied to her legs daily. The inference is that the condition was referred to

hysteria. She says that she could not feel the currents at all for the first three days. The currents were applied daily for a month. No movements took place in her legs in response to them. Whilst in the hospital she got slight bed-sores on the hips.

At the present time, Dec. 1, the right foot is in a state of calcaneo-varus, from the paralysed peroneus longus and calf muscles being unable to antagonise the tibialis anticus. The case can hardly be considered a pure example of anterior acute polio-myelitis, as the disorder of sensation, paralysis of bladder and rectum, and formation of bed-sores, showed that the mischief was not limited to the anterior cornua, but that the sensory grey matter was also rather extensively involved. But the disorder of sensation and nutrition (as well as the paralysis of bladder and rectum) cleared off, and the condition left is that of a case of infantile paralysis.

In this case the electrical examination alone is sufficient to exclude hysteria. Duchenne wrote that the electro-muscular contractility was normal in hysterical paralysis. According to my observations there are exceptions to this, which, however, is doubtless the rule. Occasionally there is a distinct, although slight, lowering of electrical excitability in the muscles in hysterical paralysis, where this has been of long duration. The lowering of excitability, however, applies to both forms of electrical excitation, and in that respect differs from the "reaction of degeneration," where the decrease in faradaic excitability is usually accompanied by increased excitability to the voltaic current. We never see in hysteria the various muscles of one limb showing differing degrees of abnormality of response to Faradism, from a condition of total absence perhaps in some, to nearly a natural state in others. Moreover, according to my observation, in hysteria applications of electrical stimulus (and especially of the voltaic current) on one or two occasions usually suffice to restore the natural excitability of the muscles (equally in all), which has simply declined apparently through disuse. A difficulty can only arise where the observer has but one opportunity of testing the electrical condition, and it is then quite possible to occur. It must be remembered that, as a distinct lowering of Faradaic excitability almost invariably signifies organic change in a nerve or nerve centre, a diagnosis of hysteria can never safely be arrived at whilst that condition persists. On the other hand, I need scarcely remind you that the preservation of a completely normal faradaic excitability in the muscles of a limb does not show that that limb is not paralysed. It would be hardly necessary to refer to this, but that I once heard it stated in a court of law that the plaintiff was certainly not paralysed, since the muscles of the limbs contracted to electrical currents! In cases of paralysis, it is only when the integrity of the grey matter of the anterior horn is disturbed, or when there is some lesion of the anterior root or trunk of the nerve, that you find decided loss of electric excitability. You may have, and frequently do have, complete paraplegia with all the muscles responding normally.

As regards the patellar tendon-reflex, I have never seen it lost in a case which proved in the sequel to be hysterical, although I am not prepared to deny the possibility of its absence in such circumstances, if the muscle has suffered from lengthened disuse.

The other patient, B—, æt. twenty-four, came in unable to stand without support. In trying to walk between two persons the left foot was seen to be in a position of varus, as shown in diagram, and as she lay in bed the foot occupied the same position, although it was not then quite so determined.

The following notes of her case were taken by Dr. Beevor, Resident Medical Officer of the Hospital:—

Lydia B., æt. 24, single, came into the Memorial Wing of the Hospital on May 12th, 1880. She had experienced much trouble and anxiety at an early age, having been forced by circumstances to occupy a position of great responsibility when she was only seventeen. She is an orphan, her father having died from phthisis when she was an infant, and her mother about two years ago, from heart and "brain disease" (hemiplegia). A brother has phthisis. There is no insanity in the family. The patient describes herself as having been quite healthy up to twenty years of age. She has never had scarlet fever or rheumatic fever. Her present illness began two years ago, with pains starting from the nape of the neck and shooting over the top of the head. After this she had pain in the spine and the

lower half of the left side of the back, for which she took chloral. She then had pain in the left arm and leg and along the left side. About three years ago she was locked in a room, and, in consequence, had a fit. According to her own account, she lost consciousness, struggled violently, but did not bite her tongue. Two attacks occurred within an hour. About three months after this she had another fit in which she again lost consciousness, but was not convulsed. After being ill for about twelve months, during eight months of which she stayed in bed, she got better, but the pain did not leave her entirely. During this time she had about fifteen fits. In April, 1879, she again had pain in the left ovarian region, which shot round her back. This prevented her from walking. Then there was pain too in the nape of her neck and back of the head, and in the left arm and leg. In June she was laid up for six weeks, then got about till September, when she became much worse, and in December was laid up. She then began taking chloral, and this has been continued. Since December she has been getting worse, and has had about three fits each month. The fits are not always preceded by any warning. Sometimes, however, before she is attacked her tongue feels too large for her mouth. She may have headache too, and pain in the right side of the face and head. There is also sometimes pain in the left ovarian region, shooting up to her head. She began to menstruate when she was fifteen and continued regular till she was twenty. Since this time she has been irregular, an interval of two months sometimes occurring between the periods. When patient was admitted she was in an excited state, praying to have chloral given to her in the afternoon and evening; none was given. On the following morning she was quieter, but said she had not slept until six a.m. Her condition on admission was as follows:—She is rather thin and pale, but not, apparently, very anæmic. She complains of pain in the head and neck and about her body. There is no curvature of the spine. The column is tender on pressure in the upper cervical and lumbar regions. The face is symmetrical. The upper limbs present no difference in size, and with each hand there is a grasp of five kilogrammes. The lower limbs are not wasted. The right thigh measures 13½ inches in circumference; the left 13¼ inches. The right calf measures 10½ inches; the left 10¼ inches. The patient as she lies can lift the right heel about a yard off the bed, and the left about a foot. The patellar tendon reflex is excessive on the right side, and still more exaggerated on the left; but there is no foot clonus on either side. Patient cannot stand without assistance. When supported on both sides and told to walk she takes a very long time to move the left foot, but brings the right foot forward more precipitately. Urged to move quickly her feet double up under her and get entangled so that she would fall. The left foot in these circumstances always assumes the position shown in the engraving. The cutaneous sensibility is not at all diminished. There are painful points in the district of the fifth nerve and brachial plexus. The electric irritability of the legs is normal, the muscles contracting to a current which excites healthy muscle. On June 2nd I was testing the sole reflex. That of the left foot was normal. In the right, however, for a minute or two tickling was followed by no response. On its being persistently continued it was evidently felt more and more strongly, and great efforts were manifestly made to restrain the reflex movements. The muscles of the legs became contracted and drew up strongly. The face was flushed, and exhibited signs of excitement. The legs were drawn up and separated as though with endeavour to get them out of the way of the tickling process. On the 8th June, after menstruating for two days, patient had a fit in the morning. She had felt faint and complained of pain in the nape of neck and back of head. Then her head felt as if it would burst, and she felt "very strong" and "as though she was mad." She screamed and struggled very much, and fought a good deal, but recovered immediately when doused with cold water. After the fit she felt weak and giddy and sleepy. She says that before a fit "her nerves beat" and keep her awake all night. Faradisation of the skin of the legs with the wire brush was begun on June 22nd, and continued daily. On July 25th the patient went for a walk with the nurse, and succeeded in going round Queen Square. Next day she walked to the Foundling Hospital and back. She was shortly afterwards discharged almost entirely recovered.

Now, this patient had suffered for three years from convulsive fits, in which she was described as losing her consciousness. The occurrence of fits in such cases as these may materially aid our diagnosis, or, on the other hand, may lead us into error. Supposing that the patient who is apparently paralysed has attacks of typical hysterical eclampsia, we have in them a symptom which, when associated with others, may tend to render a diagnosis of hysteria certain. In the present instance, although the first fit occurred after the patient had been frightened by being locked up in a room, and was therefore presumably hysterical the attacks, some of which were witnessed in the hospital, were of an epileptoid rather than hysterical character, and their occurrence lent us no aid. As I said just now, they may easily lead to error; and I shall be able to give you a striking illustration of this point.

(To be continued.)

## ON THE DIAGNOSIS AND TREATMENT OF APOPLEXY. (a)

By THOMAS STRETCH DOWSE, M.D., F.R.C.P. Ed.,  
Physician to the Hospital for Epilepsy and Paralysis,  
Regent's Park.

GENTLEMEN,—I have chosen for the subject of my lecture of to-day "The Diagnosis and Treatment of Apoplexy." At first sight the subject may appear to possess less of interest than many other subjects in connection with diseases of the brain and nervous system; yet I cannot fail to be impressed with the fact that the practitioner of medicine is frequently summoned to attend such cases, where the question of diagnosis is not always an easy matter, and where the question of prognosis becomes doubtful; and I venture to say that the question of treatment is not unfrequently more difficult than either. We will, however, take it for granted that in no case of apoplexy can the appropriate remedies be applied unless we are able to diagnose with a fair amount of accuracy not only where the lesion of the brain is situated, but it is also necessary for us to comprehend the nature of the lesion as well as its extent which has given rise to the fit of apoplexy. I hope in the remarks which I am about to make I shall show you in a clear and practical manner that my assertions are not groundless.

I need scarcely remind you that an apoplectic state of the brain may be brought about by a disorderd condition of the blood. By a diseased condition of the circulatory apparatus for the transmission of the blood either in the heart itself or, as is more frequently the case, in the vessels of the brain. Apoplexy may give rise to death in a few hours or in a few days, or it may result in paralysis. Yet, on the other hand, the concussion and compression to which the brain has been subjected may pass off and leave the patient free from any objective signs which may lead us to conclude that some serious injury to the brain has been inflicted. It would be unwise, in my opinion, for all practical purposes, to restrict the term "apoplexy" to those cases only which are associated with sudden hæmorrhage into and ploughing up the substance of the brain, and it would be in a measure unwise to apply the term apoplexy to those cases of coma which are due to renal and vascular changes and which are invariably associated with a chronic inflammation of the pia mater and arachnoid membrane giving rise to a soddened state of the brain due to the extravasation of serous fluid from the blood. I am inclined to adopt Dunglison's definition of the term apoplexy "as a form of disease characterised by the sudden diminution or loss of conscious sensation and voluntary motion usually caused by pressure on the brain." If we apply the term apoplexy to those cases only where by sudden hæmorrhage into the brain without premonitory symptoms we have complete and immediate loss of animal life, then I must say that such cases are extremely rare.

(a) A Lecture delivered at the Hospital, May 2nd, 1881.

I must briefly in the first place call your attention to the circulation of the blood in the brain. We have two systems of vessels which supply the brain with blood, namely, the basal system and the cortical system. To the elaboration of these systems we are indebted to M. Heubner, M. Duret, and M. Charcot. The basal system comprises the circle of Willis and the trunks of the cerebral arteries in connection with this circle. If the base of the brain be exposed and the arteries gently raised with the handle of a scalpel the numerous offshoots can be readily traced as they pass to supply the various ganglia. The grey matter is much more vascular than the white. We know that the post-cerebral arteries supply the sphenoidal and occipital lobes, the anterior arteries supply the anterior lobes and a large extent of the internal surface of the hemispheres as well as the subjacent regions of white matter, while the middle cerebral or sylvian arteries distribute themselves over the inferior frontal and ascending convolutions, the parietal lobe, and dip into the subjacent parts of the medullary centres, and, moreover, furnish branches to the optic thalami and corpora striata. The great psycho-motor centres of the brain are thus supplied by the branches of the sylvian or middle cerebral artery, and we shall find that this artery and its branches are more frequently the seats of hæmorrhage, thrombosis, and emboli than are the other arteries of the brain; in fact, the anterior cerebral and the posterior cerebral arteries are by comparison rarely the seats of thrombosis, embolism, or hæmorrhage. It is only reasonable to come to the conclusion that we should, as a matter of course, find that the more common seats of hæmorrhage are in the arterioles which spring almost immediately from the great arterial trunks which have been just referred to, for they resemble, as Heubner describes them, the straight shoots at the base of a forest tree, and more than this, they are not anastomosing arteries for they terminate in pencil-like tufts of capillaries; and again, the road from the heart and main arterial trunks to these vessels is short and more direct than in those vessels which supply the grey matter of the convolutions of the brain and which anastomose in every direction. Hence we find rupture of the basal system of vessels much more frequent than rupture of those vessels which form the cortical system. Pathology, indeed, teaches us the truth of this, for, as a matter of fact, in all large hæmorrhages and especially those which fill the ventricles with blood, we shall find by careful dissection that rupture has occurred either in the lenticulo-striate or the lenticulo-optic arteries, which are direct branches of the sylvian artery, or we shall find that rupture has taken place in those branches which are sent to the optic thalamus by the posterior cerebral artery, namely, the posterior internal optic artery and the posterior external optic artery; and just in the same manner and for the same reason that these arterioles are the most liable to rupture, so are they most frequently the seats of miliary aneurisms.

According to Andral and Durand-Fardel the vessels, which I have just referred to and which supply the corpus striatum and optic thalamus, were the seats of hæmorrhage in 162 out of 199 cases. Gintrac, whose laborious statistics in cerebral hæmorrhage are worthy of note, states that in a total of 751 cases of all ages he found that it occurred in different situations of the brain, in the following ratio:—Meninges 172, cortical substance of the brain 45, middle lobes of the brain 127, posterior lobes 33, anterior lobes 17, corpora striata 72, optic thalami 38, pons and cerebral peduncles 76, medulla 2, cerebellum 55. From these statistics, and from common experience no less than from the vascular anatomy of the brain, it is evident that the middle lobes of the brain in the neighbourhood of the corpus striatum and optic thalamus are the most frequent seats of hæmorrhage, and thus the most frequent sources of apoplexy.

I should like to draw your attention once more to the researches of Gintrac, in reference to the age when

hæmorrhages are most liable to take place. He states that out of 658 cases he found—

Birth	to 10 years ...	...	15 cases.
11 years	to 20 " ...	...	24 "
21 "	to 30 " ...	...	44 "
31 "	to 40 " ...	...	74 "
41 "	to 50 " ...	...	98 "
51 "	to 60 " ...	...	129 "
61 "	to 70 " ...	...	152 "
71 "	to 80 " ...	...	110 "
81 "	to 90 " ...	...	12 "

658

Now, from these statistics alone, in reference to age and localisation, we gather very important knowledge and information, which will help us to a differential diagnosis in regard to the seat, or what may be the probable seat, of lesion when we are called to visit a person who is in an apoplectic fit; and we must never forget that the same symptoms which are produced by hæmorrhage may be produced by cutting off the blood-supply by thrombosis or by embolism. My own experience leads me to the conclusion that thrombosis of the cerebral vessels, and more particularly of the cerebral veins, is not unfrequently a cause of apoplexy in cases of septic blood poisoning, where the initial symptoms of the illness have been referable to a state of so-called sub-acute rheumatism, but where, in fact, the blood has become disorganised by septic agency, and defibrination of this kind has taken place in the venous blood current, producing such defect in the cerebral circulation, ending in dissolution and death.

Although, as we have seen, apoplexy may occur at any age, there can be no question that the liability to these attacks increases from 20 years and upwards, and in, perhaps, the majority of cases the age is over 60. This is said by many observers to be due to degeneration in the coats of the vessels, either from gouty or atheromatous change, or from changes due to Bright's disease; or it may be from syphilis; and I think it is highly probable that where apoplexy takes place between the age of 35 and 45 years, that syphilitic change of the vessels is by no means an uncommon factor.

Before entering upon the consideration of the regional diagnosis of certain brain lesions which give rise to apoplexy, I would draw your attention to a condition of the brain which produces a state resembling it in many respects, but which differs from it in many and very important particulars. I allude to what is referred to by Trousseau as "apoplectiform cerebral congestion," but which is, according to this learned authority (and I may say in passing that the views expressed by Dr. Moxon recently at the College of Physicians tend to the same direction), due rather to a bloodless state of the brain, and is allied to epilepsy and eclampsia. By way of an example of this condition, a man with or without premonitory symptoms falls down suddenly in an apoplectic condition, in which state he may remain for some hours; but the application of cold to the face, and sinapisms to the calves, or an injection of common salt by the rectum, soon restores him to a state of consciousness; and on the following day all the symptoms have disappeared.

Trousseau (a) gives many cases of this condition, and I would ask you to allow me to narrate one of them:—"Some time ago I was fetched in haste to see a neighbour, aged 70, who had been seized with apoplexy on the Boulevards. He had been insensible for a quarter-of-an-hour, but was recovering his senses as I arrived. He did not yet recognise me, however, and looked vacantly round, moving his arms and legs about without being conscious of it. His lips and nose were swollen, and his eyes injected. By degrees, and within a few hours, he recovered entirely, without my having had recourse to any active measures. His valet then informed me that his master had, in the last two or three years, had several attacks of

(a) Trousseau, "Clinical Medicine," vol. I.

the same kind, and that the symptoms had passed off in the same way, once after bleeding, and on the other occasions after a mustard foot bath. In the same year I was consulted by a solicitor from the country, aged 35, who in the course of the previous six months had suffered from three apoplectic fits. He had been bled and purged on each occasion to his great satisfaction, and leeches were applied once a month round his arms. The last attack had occurred as he was going upstairs, on his return from some important pleadings. His head had struck against the stairs. The apoplectiform phenomena had lasted an hour at the most; and when I saw him his intellect, sensibility, and power of motion were perfectly normal. I can with difficulty believe that apoplexy occurs in persons aged 37, particularly when the attacks return every two months. It immediately occurred to me that the case was one of epilepsy, and I suggested it to the medical man who had sent the patient to me. His answer was that nothing authorised my suspicion, and that convulsions had never been noticed. I still maintained my opinion, however, and shortly afterwards, the poor man had in court a regular epileptic fit, which, unfortunately, left no doubt in anybody's mind; and he was compelled to give up his profession."

Although Dr. Trousseau, with his large experience and consummate clinical observation, could readily diagnose the epileptic from the apoplectiform state, I feel assured that mistakes may and do arise in reference to this matter; but I have often been led to a right diagnosis by carefully inquiring after the patient's habits and history, particularly in regard to epileptiform conditions, such as sudden and transient attacks of vertigo and unconsciousness; whether there had been nervous twitches preceding the attack, and whether anything like convulsions of the limbs had been observed, or involuntary discharge of urine during sleep; whether the pillow was ever found wet with saliva in the morning, and so on. I must repeat that it is well to keep these points in view if we would diagnose the condition of the apoplectic or the epileptic with any degree of certainty, and several cases of epilepsy have come under my immediate observation which were said to be cases of apoplexy, but which, by a little careful inquiry, have turned out to be purely epileptic. I remember well the case of a man who was admitted under my care into the Central Sick Asylum, at Highgate, said to have suffered from apoplectic seizures, and on one occasion I was called to him during the night, and found him quite unconscious, with stertorous breathing; yet on the following morning he was quite well. A few nights after this he got out of bed, went to the lavatory, seized a poker, and commenced smashing everything within his reach. He was quite unconscious of what he was doing. I had him carefully watched on the following night, and just about the same time he had a confirmed epileptic seizure. I will not here attempt to discuss the question whether, in these cases, the brain is in a state of anæmia, or congestion, it will be sufficient for my purpose if I have shown that cases of epilepsy may be mistaken for apoplectiform cerebral congestion, and I shall, I hope, be able to show you more clearly as I proceed how the one may be diagnosed from the other. A remarkably interesting case of apoplexy from meningeal hæmorrhage came under my care some years ago, which shows how very careful the physician has to be not to jump at rash or hasty conclusion. I was called hurriedly to the ward to see a young man, aged 22, who was said to be in a fit. I found him lying upon his back quite unconscious, and every muscle of his limbs and face was in a state of clonic convulsion, and although I was somewhat doubtful as to the nature of the attack, I told the nurse to watch him, and then to report to me how he was. I saw the case one hour after this, and the man's condition remained precisely the same, and within thirty-six hours of the time of his seizure this young man was dead; and when the calvarium was removed the convulsions of the left hemisphere were found to be enveloped in blood. In the same ward, and within a few days of the case just

narrated, I was called to see a man of about the same age. He was suffering from renal disease and uræmic convulsions, and had I not been aware of this I should possibly have concluded that this man too, had meningeal hæmorrhage. Small aneurismal dilatations of the capillary vessels of the grey matter of the cortex of the brain, as well as of the branches which supply the corpus striatum, are much more frequently the seat of small hæmorrhages which give rise to apoplectiform seizures than, I think, is usually supposed; and, in making post-mortem examinations in persons over fifty, who have died from some non-cerebral affection, I have observed in connection with these military aneurisms the traces of slight extravasations, with degeneration of tissue which must have given rise to some objective signs during life, although the evidence of these signs might have been of the most transitory character. Some six months since I was travelling in a railway carriage with a well-known public man, over 50 years of age, and whilst we were conversing I noticed some very abnormal movements in the extensor muscles of the thumbs of both hands, and seeing that my attention was drawn to his hands, he asked me what there was to attract my notice, and I then remarked to him in a joking way that his cerebral grey matter was unstable, and that he had abnormal discharging lesions, possibly, from an impaired circulation of the brain. He smiled, saying that he felt a little stupid and faint sometimes, and I was not at all surprised when I heard of this gentleman's death from apoplexy, although, at that time, when I last saw him, he was in the enjoyment of the most robust health.

I will now put the question—Are we justified in coming to the conclusion that certain persons, either from heredity or bodily conformation, are specially predisposed to apoplexy? I should certainly say that such was the case, but with regard to heart disease as a cause of apoplexy, my experience quite bears out the statement of Dr. Walshe, who arrives at the conclusion that hypertrophy of the left ventricle of the heart exerts no agency in producing apoplexy. Generally, hypertrophy of the left ventricle of the heart is associated with mitral or aortic lesions, which are conservative as regards the effects of the augmented power of this ventricle upon the cerebral circulation. There can be little doubt, however, in my mind, that a dilated right heart interferes greatly with the cerebral circulation, and is, in a large number of cases, causative, not only of cerebral congestion, but of positive hæmorrhage from the vessels of the brain, and particularly in those cases which occur when the patient is said to be asleep. We know that a dilated right heart is often associated with engorgement of the liver and abdominal circulation; and no less do we find accompanying this state an engorgement of the vessels of the brain. I believe, however, that such a condition of heart is equally, if not more, likely to give rise to apoplectiform congestions, military aneurisms, and thrombosis, than to hæmorrhage into the brain itself. Fits of apoplexy, we know, do occur after eating too hearty a meal of indigestible food, straining at stool, violent muscular exercise, sexual intercourse, mental excitement, and so on. Now, in these cases, my impression is that a weak right heart is almost always the predisposing, although not the exciting cause. Where there is disease of the mitral or aortic valves of the heart, we may then anticipate, should an apoplectic fit arise, that embolisms have plugged one or more of the cerebral vessels.

(To be continued.)

#### ANTAGONISM IN ACTION BETWEEN ATROPIA AND MORPHIA.

By HERBERT PARSONS, M.R.C.S.

THE following case, as having some bearing on the question of the antagonism in action between atropia and morphia, may be worth recording:

A strongly made, though very unintellectual young

man, set. 19, going out as a miner from Cornwall to Brazil, fell down while disporting himself on the deck and struck his abdomen against a block, experiencing from it so much pain that he fainted. This was in the tropics with an average daily temperature of 80° F.

When first seen he was suffering apparently very great agony, tossing about and yelling and moaning, and there was extreme tenderness at the epigastrium. In order to relieve the pain, I at once gave him a quarter of a grain of morphia hypodermically, and as this produced no effect, repeated the dose in half-an-hour. Very shortly after the second injection the pupils contracted, the violent pain lessened, and he broke out into a profuse perspiration, but at the same time a series of violent convulsions commenced, and continued at intervals of half a minute. During the attacks all the muscles of the body became firmly contracted, trismus and opisthotonos being present in a marked degree. Regarding this symptom as the result of the morphia, I gave him two doses, each containing pot. bromide, ℥j., at intervals of a half hour, at the same time keeping ice applied to the spine. The abdominal pain was of course aggravated to an extreme degree during the spasms, but as there was no failure of pulse or general abdominal tenderness, I did not consider that there was any likelihood of a serious internal rupture. These remedies proving unavailing, I then injected under the skin one-fortieth of a grain of sulphate of atropia. The result of this was the pupils, previously highly contracted, became dilated, the skin from being moist became dry, and the patient also began to show the usual characteristic belladonna delirium, but the convulsions went on precisely as before. Here the atropia undoubtedly counteracted some of the effects of the morphia, but not the one which it was meant to counteract. Finally, chloroform had to be administered, and after he had been kept under its influence for two hours the patient slept all night, and woke in the morning without pain or even headache, nothing remaining but slight epigastric tenderness, which also disappeared in a few days.

Though in this case the exhibition of remedies was not fortunate for the patient, yet it was a case to demonstrate well the actions of the drugs employed, especially in showing the somewhat rarely seen convulsant properties of morphia carried to an extreme degree. During the whole time there was no alteration in the strength or volume of the pulse, nor, though the skin felt very hot and dry after the atropia, was there any elevation of temperature marked by the thermometer. I may mention that the morphia solution employed both on myself and two other persons produced the usual effects.

As in this case there was at no time any appearance of dangerous opium poisoning, of course it has no bearing on the main question as to whether atropia, by stimulating the respiratory centres, will prevent death in such a case.

## Clinical Records.

### ST. BARTHOLOMEW'S HOSPITAL.

*A case of Disease of the Knee-Joint, with Amyloid Disease and Hydrocephalus—Amputation—Recovery.*

Under the care of Mr. MORRANT BAKER.

(Communicated by Mr. SIDNEY DAVIES from notes by Mr. HEWER, Dresser.)

THOMAS S., set. 10, was admitted into St. Bartholomew's Hospital on January 12, 1881. He gave the following history: Two years ago, as he was coming out of school, he fell down the steps and injured his left leg. Directly after the accident the limb was not very painful nor enlarged, but five or six days after, the left knee began to grow larger and larger, and the heel was at the same time drawn up, so that the patient could only walk on his toes. Three weeks after the accident he was taken to the Children's Hospital (Great Ormond Street), where he became an out-patient, and the knee was treated with Scott's dressing, and a bandage. The knee at this time was not at all painful, but simply enlarged, and the

heel drawn up. He remained an out-patient for four months, when, no improvement being visible in the knee, he was admitted as an in-patient, and extension was made with a weight. He remained at the Ormond Street Hospital for six months, when he was discharged, the knee having become straight, but its condition otherwise unchanged. He was sent out with a plaster of Paris casing round the joint.

Three weeks after his discharge an abscess formed on the front of the ankle; this was treated with zinc ointment, and soon healed up. His friends subsequently succeeded in getting him taken in at the London Hospital. Here the joint was opened antiseptically on the inner side, and a drainage tube inserted. The wound discharged a great deal, and was dressed every three days for a month, at the end of which time the tube was removed, the wound syringed out with diluted carbolic acid, and dressed with oiled lint. The wound did not, however, heal up, so a larger drainage tube was inserted, and kept in for some time, after which it was removed and the wound poulticed. The patient was told that the limb ought to be removed, but that he was not in a fit state to bear it. He was taken home, and during his stay there his general health was improved considerably.

His persevering friends at last brought him to St. Bartholomew's Hospital, to see Mr. Baker, who decided to admit him.

*Condition on Admission.*—Head hydrocephalic, and somewhat dolichocephalic. (This had been his condition from birth, and when quite young his head had been tapped). Intellect above the average of acuteness. General condition pale and anæmic; very thin. Abdomen distended; veins much enlarged. Liver greatly enlarged downwards, occupying the whole of the right hypochondriac and epigastric regions, and parts of the right lumbar umbilical, and left hypochondriac regions. Spleen also much enlarged, reaching down to the level of the anterior crest of the ilium. Left leg altogether larger than the right, which is very much emaciated. Left knee much swollen, not painful (at no time had there been any pain). Patient is unable to flex it at all. There are two sinuses on the inner and outer sides of the joint respectively; both discharge freely. Femoral glands not enlarged. Heart and lungs normal. Pulse 118, small, regular. Temp. 99°. Bowels regular. Urine 1011, slightly acid; a trace of albumen present; no sugar.

The following notes indicate the subsequent course of the case:—

Jan. 14th.—Patient sleeps well. Appetite good. The knee is not at all painful. It is kept in a poultice, and discharges a good deal.

16th.—Appetite very good. Abdomen and knee in same condition.

17th.—Urine 1016; a trace of albumen.

20th.—Condition unchanged. Patient is in good spirits, and free from pain. He was taken into the theatre for a consultation, at which there was a general consensus of opinion that amputation should be performed.

22nd.—The thigh was amputated in the lower third. The surrounding tissues were hardened and brawny. The knee-joint was full of pus, and completely disorganised. A strip of gutta-percha tissue was inserted at each end of the wound, and the stump dressed with oil lint. Urine passed, 2½ pints; contained a trace of albumen. Temp. normal; pulse, 122.

23rd.—Patient passed a bad night. Temp. 101° 6. Appetite poor. No pain. The stump was dressed at 1 p.m. Very little discharge; no hæmorrhage.

24th.—Temp. 101° 4; pulse 142. Had a good night. Appetite much improved. Patient in capital spirits; quite free from pain. Stump looks healthy. Very little discharge.

25th.—Temp. 100° 3; pulse 118.

26th.—Sleeps and eats well. Urine, 2½ pints, 1015; more albumen; excess of indican.

29th.—Stump is now poulticed.

Feb. 1st.—Going on well. Urine contains only a trace of albumen.

2nd.—Liver much smaller than when he came in.

3rd.—No albumen in urine.

15th.—Poultices discontinued. Water dressing applied. Liver smaller. Urine contains a trace of albumen.

March 7th.—Patient makes steady progress. Scarcely any discharge from the stump. Liver and urine the same.

25th.—Patient is going to try crutches for the first time, and is going out in a few days.

The dulness of intellect which usually accompanies hydrocephalus was conspicuous by its absence in this case. The

young patient gave quick and intelligent answers to all questions, and from him was obtained the very complete history given above. He also read several books adapted to boys of twelve to fourteen years during his stay in the hospital.

Another interesting point in the case is the involvement of the liver; its immense size on admission, and decrease subsequent to amputation of the thigh. There is little doubt that the enlargement was due to amyloid disease, the result of the long continuing disease of the knee-joint. It would be interesting to find out to what extent the enlargement will disappear, now that its cause has been removed. The spleen and kidneys also appear to have been affected by the amyloid disease.

## Special.

### A PROGRAMME FOR THE OFFICERS OF THE ARMY MEDICAL DEPARTMENT.

We have received a paper bearing the above heading. The writer of it, after declaring that he stands firmly by the unification or non-regimental system, proceeds to show that he himself is extremely dissatisfied under the very system he thus professes to "stand firmly" by, and that, in fact, the grievances of his department are great and various. The nature of some at least of those grievances, and of the means he proposes for their removal are thus enumerated.

In the recent Afghan War, 200 medical officers of various ranks were employed in very trying duties. The *Gazette* of honours has now been published; medical officers are entirely excluded from the promotions, and only three C. B.'s have been given amongst them. The surgeon-general, a C. B. of 26 years standing, has received no reward of any kind. Owing to the unjust position the Horse Guards takes up to the medical service of the army, many of the so-called *combatant* officers are encouraged to do their utmost to depress us in their every-day dealings with us. These officers, in no way our superiors, either in status, education, attention to duty, or patriotism, are encouraged by the neglect shown to us by the authorities, to treat us as if we did not form part of the army.

The principle that underlies the following paragraphs is to endeavour to secure equality within the army with the combatants in everything relating to rank and reward, and to give way at other points, so that a *modus vivendi* may be arrived at.

Our aim should be as follows:—

1. The union of the army medical department officers and the men of the army hospital corps into one body. This union is essential for the development of *esprit de corps*.

2. The existing system of dividing the officers of the army into combatants and non-combatants to cease. The officers now called combatant to be styled "executive," and the existing non-combatants to be called "administrative;" and all rewards for campaigns to be equally shared by all officers of every branch of the service.

3. The existing system of relative rank to be replaced by definite military rank with military titles, as in the pay department of the army. We propose that the director-general should be made an honorary lieutenant-general as well as director-general of the medical corps. The surgeons-general, who now have the relative rank of major-general, to be given definite honorary rank as major-general, and to be designated thus: Major-General Smith, Surgeon-General, A.M.D. In like manner the Deputy-Surgeons-General to have their present relative rank as colonel in the army, converted into definite honorary rank, and to be designated thus: Colonel Brown, Deputy-Surgeon-General, A.M.D. The brigade surgeons to keep their existing titles, but to be given in addition definite army rank as lieutenant-colonels. All the existing pay, allowances, widows' pensions, forage, prize money, batta, &c., would be considered as *departmental*, and be kept as at present, but army rank would be placed on an equality with the average of the combatants, as certified by the War Office actuaries, giving five years to credit for college service. Thus, a young medical officer would receive the pay and allowances of a captain, but he would have to serve four years as a lieutenant in the medical corps, which with his five years' college service, would make up nine years as a subaltern before getting his rank as captain. At twelve years' service we would get all the pay, allow-

ance, prize money, batta, forage, widows' pensions, of a major, as a *departmental* matter, but not army rank of major until about fourteen years' service. At twenty years' service we would get all the pay, allowances, and pensions as a lieutenant-colonel as at present, but not the rank of lieutenant-colonel until after about twenty-one years' service as medical officer.

4. Brevet promotion, one of our greatest needs, should be given us exactly as in the combatant ranks. Our departmental rank not to be increased but to remain like their regimental rank, but honorary military brevet rank, carrying military titles, to be given us. Thus, if a captain in the medical corps distinguishes himself in field service, make him an honorary major, but keep his name still in the former place in the corps list.

5. We claim this defined military rank, not because we wish to ignore medicine, but solely to place ourselves on a defined footing as part of the army, and to protect ourselves by defined military status from the every-day recurring attempts to deprive us of all rank within the service. Italy, America, Switzerland, and other States have so organised their medical service. To-day we live in hopeful times, and England is herself reforming her army, abolishing the harsh discipline that crushed the service, and elevating as far as she can the status of the soldier. The same measure which the people of England are giving to the private soldier, we, her army doctors, also need.

## FRANCE.

[FROM OUR SPECIAL CORRESPONDENT.]

COMPULSORY VACCINATION.—After a great deal of discussion and several passages of arms, the learned Société Académie de Médecine has adopted its report relative to compulsory vaccination and re-vaccination. Its conclusions are, 1st, L'Académie de Médecine believes that a law rendering vaccination compulsory would be a public benefit. 2nd, As to re-vaccination it ought to be encouraged in every possible way, and even imposed by the rules of the administration when thought necessary. The report has been forwarded to the Government, and a Bill has been already framed on the subject. It will meet with little opposition.

ELECTRICITY IN ACCOUCHEMENTS.—M. Apostoli, a celebrated gynecologist, communicated the results of his researches relative to a new application of electricity in accouchements. From the study of thirty-three cases observed during the last two years, of which eleven were miscarriages, and for which he applied the battery over five hundred times, M. Apostoli draws the following conclusions:—1st, Faradisation of the uterus is always absolutely inoffensive. 2nd, Faradisation is a constant sedative. 3rd, Faradisation abridges considerably convalescence in accelerating the involution or retraction of the uterus. 4th, Faradisation accelerates the return and regular exercise of all the functions. 5th, It preserves the woman from all uterine complications. It is the true and effective treatment for uterine deviations, its action upon the womb is more prompt and energetic than ergot. This communication was listened to with great attention, and marked for examination.

TRANSVERSE FRACTURE OF THE TWO PATELLÆ.—Simultaneous transverse fracture of the two patellæ caused by muscular contraction is rare enough to deserve notice. Such a case entered the service of M. Pallalon, of the Hôtel Dieu, recently. A young man, who was neither scrofulous nor addicted to alcohol, æt. 22, was playing at leap-frog, and was about to take the jump when he stopped suddenly, his limbs bending involuntarily under him; at the same time he heard a distinct sound of snapping. He was carried to the hospital where it was discovered that the two patellæ were fractured, a space of nearly an inch separating the fragments. At the same time considerable effusion was present in the joints. The fragments being brought together as well as possible by means of sticking plaister, fifteen days sufficed for union to commence, and in three weeks afterwards all the apparatus was taken off.

ATROPINE.—Toxic effects of atropine having been found to manifest themselves where this agent was employed in the ophthalmia of the very young and the aged, a new dilating agent has been discovered by M. Galezowski, the renowned

oculist of Paris, to which he has given the name "homatropine." Having had an extensive experience of it he considers it to be a very good dilator, only that its influence is not prolonged over twenty-four hours. It possesses no irritating principle, and can be employed with perfect safety for children and those advanced in years.—Speaking of atropine, a Dr. Anger recommends it in solution (1 in 1,000) for easing the pain of cancer. Compresses impregnated with this solution and applied to the painful parts are very effectual. He affirms that he has never seen symptoms of absorption such as dilated pupils, dryness of the throat, &c. He considers the action is quite local and consists in contraction of the vessels with diminished sensibility. The compresses are renewed three times a day and covered with oil silk to prevent evaporation.

**DIPHTHERIA.**—M. Vidal uses the following collutory in diphtheria, for which he claims an almost specific action:—Tartaric acid two and a-half drachms, glycerine half an ounce, peppermint water seven drachms. A brush dipped in this solution is made to touch every three hours the diphtheritic patches, which soon reduce themselves to a pulpy liquid mass which is afterwards easily removed. In the interval of the applications of the tartaric acid the false membranes are touched with citron juice.

(Continued from page 493.)

#### THERAPEUTICS OF ALKALINE WATERS—continued.

**Vals.**—It has been stated in some quarters that Vals furnishes the most concentrated of all the alkaline waters. A reference to Prof. Tichborne's analyses (p. 318) is sufficient to dispose of this assertion which was perhaps founded on M. Ossian Henry's analysis. That chemist found a much larger proportion of soda present, but whatever may have been the amount in the water when he examined it at the springs, the only indications for prescribing the bottled waters are furnished by their chemical qualities as now imported. The highest proportion of carbonate of soda found by Prof. Tichborne was 13.27 grains in ten fluid ounces, while Vichy yielded 24 grains. This is in accord with our clinical experience for we have never considered Vals as strong as was represented. It is assuredly a less powerful antacid than Vichy. Still these waters are useful agents, and may be employed in a similar way to those of Vichy, bearing in mind their relative strength, a point now decisively settled. The *Précieuse* and *Madeleine* springs are regarded as more tonic, inasmuch as they contain a fraction more iron. It is, however, scarcely appropriate to apply the term chalybeate to such waters. The claim of the *Dominique* spring to be termed arsenical will be spoken of hereafter. The *St. Jean* is so weak that it is sometimes spoken of as a table water, but it contains five grains of antacids in the half-pint, and may therefore claim to be medicinal. It is useful when a

weak alkaline water is required, and therefore is to be specially distinguished from the other Vals waters.

**Bilin** water has been lately imported, and is strongly alkaline, as much so, in fact, as the weakest spring of Vichy, but much less so than the others. The amount of earthy carbonates is also small, so that the water is not "heavy" on the stomach. It is a very good useful member of the group of strong alkaline waters.

**Ems.**—In the waters of Ems the proportion of carbonate of soda is much less, but its action is re-enforced as well as modified by the chloride of sodium which is present in sufficient amount to give Ems a claim to be included in a group of waters containing the two salts. We have already shown that the chloride is a corrigent as well as a most useful adjunct. It stimulates the stomach and bowels, increasing the secretion of the mucous membrane, and promoting tissue metamorphosis. It is chiefly due to the combined effects of the two salts that Ems retains its celebrity, unless we are to attribute a greater effect to the climate and surroundings when patients resort to the spa. In catarrh of the stomach and other conditions requiring an alkaline water of less strength than Vichy, but more stimulating in its nature, Ems may be tried. In catarrh of the respiratory mucous membrane, Ems also long enjoyed considerable reputation, but in laryngeal and bronchial cases, we venture to assert that it is only seldom that the depressing and admittedly rather damp climate of this valley, with its mid-day heat, and evening and morning mists, should be recommended. It was at one time extolled for consumption, but all have now given up recommending it in that disease. The fame of the "Bubenquelle" for sterility has quite passed away, but the place is much resorted to for the treatment of diseases of women, when a course of baths and alkaline salt waters are desirable. The bottled waters are not so much employed in this country as they might be, considering their mildness and the indications we have given for their use.

#### THERAPEUTICS OF ARSENICAL WATERS.

Some years ago no little sensation was caused by the discovery of traces of arsenic in several mineral waters. Many at once concluded that the full therapeutic value of arsenic could be obtained by drinking such waters, and in the case of spas previously in high repute no small share of their virtue was attributed to the newly discovered ingredient. It was, however, very soon found that arsenic was far more generally distributed than had been supposed, and so many spas were able to boast of its presence that any specific effect was seen to be doubtful. Moreover, in all cases only minute quantities of the element were detected in the waters—mere traces, certainly not enough to enable us to choose such media for the administration of ordinary doses of arsenic; in most cases it would require from half a gallon to a gallon of the mineral waters to be imbibed daily in order to obtain a moderate therapeutical dose. Further, this medicament was associated with much larger quantities of other substances to which it was only natural to attribute the chief effects of the waters. The arsenic was most frequently found in alkaline waters, and in such cases could only be regarded as an adjunct to the soda. Accordingly few now insist on mere traces of arsenic as characteristic of such waters. Nevertheless, there are

two or three spas which have obtained a certain repute for their so-called arsenical spas. Among these the St. Dominique of Vals, a weaker alkaline spring than the others at the same place has been pushed. Professor Tichborne finds it only contains 0.05 grains per gallon. Some of the success of Mont Dore is also attributed by some to a minute quantity of arsenic found in the waters. But the chief arsenical spa up to this time has been La Bourboule where there are three alkaline springs containing a good deal of chloride of sodium. In one of these Professor Tichborne finds .05 grain in ten ounces of the water, which is present in the form of arsenite of sodium. (See his analysis, *ante*). Another water he has analysed is that of Court St. Etienne which differs much from others as it contains only 18 grains of solid substances in a gallon, and thus the arsenic can be taken almost pure. The amount present is .05 gr. in ten ounces, and it is present as arseniate of soda. This water is then not an alkaline one and what effects it may be found to have will be fairly attributed to the arseniate of soda.

The indications for the use of arsenic are sufficiently distinct, and if the medicine be present in sufficient quantities in any mineral waters advantage can be taken of them to provide an additional mode of administration. If an alkali be at the same time indicated La Bourboule may be given; if otherwise, a trial may be made of Court St. Etienne. In either case it will naturally occur to the reader that not seldom the use of the pharmacopœial preparations of arsenic may be equally useful and more reliable. If need be they may be reinforced by alkaline and other mineral waters.

H.R.H. THE DUKE OF EDINBURGH, in response to the request of the committee has consented to become the Patron of the International Medical and Sanitary Exhibition.

THE Committee of Management of St. Peter's Hospital for Stone have decided to increase the staff, by the addition of a second assistant surgeon. The election takes place the first week in July.

THE late Miss G. F. Downing, of Appin, has bequeathed to the Edinburgh Royal Infirmary £500, to the Glasgow Royal Infirmary £500, and to the Edinburgh Medical Missionary Society £1,000.

DR. A. WHITE BARCLAY of London, Dr. A. Ransome of Manchester, Dr. De Chaumont of Netley, and Dr. Corfield of London, have been appointed examiners for the sanitary science certificate at Cambridge, the examination for which commences on Oct. 4th.

MR. E. J. O'MULLANE, L.K.Q.C.P.J., has been presented with a very flattering testimonial by the members of the Portland Lodge of the Nottingham Order of Odd Fellows. The testimonial consisted of an illuminated address, mounted in a gold frame, and expressive of the subscribers' high sense of the value of Mr. O'Mullane's professional services as their medical officer, and of the estimation in which they hold him as "a gentleman, a scholar and a philanthropist."

“SALUS POPULI SUPREMA LEX.

WEDNESDAY, JUNE 11, 1881.

### PROVIDENT DISPENSARIES.

THE well meant efforts that have for some time been directed to perfecting means whereby the ever-growing burdens thrown on charitable institutions by numerous applicants for hospital relief, appear to be shaping themselves into a definite aim, and it may be well to consider how far success is likely to follow fulfilment of the proposed changes. These, as embodied in a prospectus issued by the projectors of “The Metropolitan Provident Medical Association,” are of a nature to demand the sympathy and aid of all who can be assured that, under the arrangements sketched forth, other and greater evils than those it is sought to remove, may not be encouraged. In former references to the same and similar schemes, we have urged the value of any reform in the system of affording medical aid to the poorer classes, which will tend to create a spirit of independence among them, and paralyse the immense pauperising influences at work wherever a considerable hospital is established. We are convinced that much of an unsatisfactory character distinguishing the relations between the medical profession and the less or little wealthy members of the general public, has an origin not wholly separate from the conduct of medical men themselves. That large numbers of poorly circumstanced persons are, and have been, willing to emancipate themselves from the dependence associated with acceptance of gratuitous treat-

ment at hospitals, is amply evidenced by the success achieved by a majority of so-called private dispensaries. These are confessedly of comparatively recent growth, but at this time there is no street of any importance in densely populated districts, where one or more does not drive a prosperous trade; and this by reason of the fact that they afford means of obtaining advice and drugs at an almost nominal charge. That they can be made remunerative undertakings to the owners however, no doubt is felt; and the manner in which success is accomplished was ably shown in the articles on the subject published in our columns last year by "A. B." It is unfortunate that there should be strong inducement in connection with such institutions, to make them *merely* trading concerns; it is this which so seriously detracts from the value they might otherwise possess, since it offers encouragement to unprincipled persons to enter on the duties connected with them in no other spirit than that dictated by *auri sacra flammæ*. Without the skill, born only of a long experience, to detect swiftly and surely the signs of illness, and without the ability to treat it aright, it must be admitted that many private dispensaries afford only a mockery of assistance to the applicant resorting there for help; and, again, though the possibility of prescribing faithfully and remuneratively to large numbers, at a small individual rate, has been demonstrated, yet the temptation to tender worthless mixtures in place of sound medicines is one too generally indulged. Consequently, the few honest dispensary owners suffer in reputation through the short-comings of the many dishonest ones; and the system itself, capable as it is of great benefit to the poor, is discouraged and recognised only in respect to the harm that is done. The facilities it affords too for illegal practices are not overlooked or omitted; this also has done very much to generate a feeling of distrust of all who avow any connection with private dispensaries.

None the less, however, the problem remains, how to deal with the vast numbers of non-pauper poor at all times existing to need a doctor's care. The provident plan seems particularly applicable to them, and we cannot but regard as a happy idea that of carrying it out on a business basis, as proposed by the association above alluded to. This consists of a company of shareholders whose subscribed capital will be devoted to the purchase, building, and fitting of appropriate dispensary offices wherever there may appear sufficient need of them. Membership of these local institutions will be dependent on periodical contributions to their funds, and will carry with it a right to professional attendance and medicine during illness. The fees payable will be fixed so as to be within the power of the artisan class to pay, while being at the same time sufficient in the aggregate to maintain the institutions in efficient working order, and afford remuneration to the medical men associated with it. The selection of these latter, a point on which the smooth working of the whole arrangement must mainly depend, is to be on a plan that will be highly commended. The appearance even of coercion cannot but be fatal to any attempt to aid the masses; and hence the rule by which freedom of choice respecting the medical attendants is provided for is a subject for congratulation to the new association.

It provides— "The Medical Officers shall be elected from persons who are qualified to practise under the Medical Act.

There shall not be more than one member of any firm of Medical Practitioners on the Dispensary staff at one time. Assistants shall not be employed without the permission of the Committee, and Assistants so employed must be duly qualified.

"The Medical Officers will attend at the dispensary on such days and hours as the Managing Committee deem requisite, and will visit their patients at their homes whenever their cases require it.

"They shall each keep a register, according to a prescribed form, of all cases treated by them, and report quarterly to the Committee on the statistics of health of the members under their care.

"A fixed proportion of the sums received from members will be divided at the end of every quarter or half-year among the medical officers in proportion to the amounts received from the members registered under their names. This will be in addition to their midwifery fees, and to a contingent interest, calculated as above, in any net surplus there may be after the annual accounts are made up.

"The midwifery fees payable to the medical officers shall be fixed by the managing committee.

"Candidates for admission to Friendly Societies affiliated to Provident Dispensaries shall be examined by a medical officer of the Dispensary on the production of an authorisation from the Secretary of such Society."

It is further to be understood, in the terms of the suggestions made at the public meeting held to inaugurate the promotion of the association, that "in order that each family may be able to choose its own medical attendant, and that skilled professional men may be induced to exert themselves in the service of the dispensaries, the managing committees should elect a sufficient medical staff, who should be paid in proportion to the amounts received from the members registered under their respective names. It being added that this is better for all parties than any form of payment by fixed salary."

It may very probably occur to some the whole scheme will be regarded with extreme jealousy by many in the medical profession. We do not, however, consider that their hostility toward it will be justified; so long, that is, as there is an entire avoidance of all appearance of illegitimate tampering with absolute freedom and independence on the part of the members of the several dispensaries. The aim held in view is a good one; and honestly carried out in the spirit already indicated, it will benefit public and profession alike.

#### POOR-LAW MEDICAL SUPERANNUATION IN IRELAND.

THE Council of the Irish Medical Association has, we rejoice to observe, after prolonged consideration and negotiation with those whose influence is desired, matured its Bill to place superannuation for Irish Poor-law medical officers on a more satisfactory footing than it at present occupies. The Bill was submitted to the General Meeting of the Association, and approved by it, and we now publish it for the information, and, we hope, for the approval, of those concerned in the matter:—

Whereas it is expedient to alter the law providing superannuation allowances for medical officers of unions and dispensaries in Ireland.

Be it, therefore, enacted by the Queen's Most Excellent Majesty, by and with the advice and consent of the Lords, Spiritual and Temporal, and Commons in Parliament assembled, and with the authority of the same, as follows:—

I. Repeal—

32 and 33 Vic., chap. 50, the whole Act;  
35 and 36 Vic., chap. 89, part of sec. 2, viz.:—the words "Registrars of Births and Deaths," and "Registrars of Marriages."

but such repeal shall not affect any superannuation allowance granted, or act done, before the passing of this Act.

*cf.* "The Superannuation Act, 1859," 22 Vic., cap. 26, sec. 2.

II. The board of guardians of any union in Ireland shall, with the consent of the Local Government Board for Ireland, grant to any medical officer of said union, or any medical officer of a dispensary district in said union, an annual allowance, upon his retirement from said office, at the following rates, that is to say—

To any medical officer who shall have served ten years and upwards, and less than eleven years, an annual allowance of ten-sixtieths of the annual salary and emoluments of his office.

For eleven years, and less than twelve years, an annual allowance of eleven-sixtieths of such salary and emoluments:

And in like manner a further addition to the allowance of one-sixtieth in respect of each additional year of such service, until the completion of a period of service of forty years, when the annual allowance of forty-sixtieths may be granted, and no addition shall be made in respect of any service beyond forty years.

*cf.* Medical Officers' Superannuation (Ireland) Act, 32 and 33 Vic., cap. 50, sec. 1.

III. The board of guardians of any union in Ireland shall, with the consent of the Local Government Board for Ireland, grant to any medical officer of said union, or any medical officer of a dispensary district in said union, who, after ten years' service, shall have become incapable of discharging the duties of his office with efficiency, by reason of permanent infirmity of mind or body, or of old age (such age being not less than sixty years), upon his resigning, or otherwise ceasing to hold his office, an annual allowance of two thirds of his salary and emoluments at the time of his retirement.

*cf.* The Superannuation Act, 1859, 22 Vic., cap. 26, sec. 4.

IV. A number of years, not less than ten or exceeding twenty, according as the Local Government Board shall see fit and direct, shall be added to the number of years during which any medical officer shall have actually served in the Poor-law service, and the amount of superannuation or retiring allowance to be granted to such medical officer shall be computed thereon.

*cf.* "The Superannuation Act, 1859," 22 Vic., cap. 26, sections 5 and 6.

V. It shall be lawful for the Local Government Board, upon any medical officer being compelled by reason of severe bodily injury occasioned (without his own default) in the discharge of his public duty, or constrained from infirmity of mind or body, to vacate his office before the completion of the period of service which would entitle him to a superannuation allowance, to direct that the guardians of the union in which said officer served shall pay him such sum of money, by way of gratuity, as the said Local Government Board may think proper, but no such gratuity shall exceed the amount of one month's pay and emoluments for each year of service.

*cf.* Union Officers' Superannuation (Ireland) Act, 28 Vic., cap. 26, sec. 2.

VI. All allowances payable under the provisions of this Act shall be payable to, or in trust for such medical officer only, and shall not be assignable or chargeable with his debts or other liabilities.

VII. The term salary and emolument shall include all salaries, fees, allowances, and emoluments receivable by said medical officer in virtue of his office, and from every office connected therewith by statute.

This Bill, it will be observed, is a simple application of the Civil Service Superannuation Act of 1859—known as Playfair's Act—to the case of the Irish Poor-law Medical Officers. Under it every such officer will, if it passes, be entitled to a pension as a matter of right, and the special circumstances of each applicant are provided for by the various sections.

A Poor-law medical officer who has served ten years will, on retirement, irrespective of his condition of health, receive a sixtieth of his total salary and emoluments for each year of his service. His service is to be counted by adding to the actual time during which he has held office a term of not less than ten and not more than twenty years, as the Local Government Board may direct. Thus, supposing the Board fixes fifteen years as the addition, a medical officer who has served fifteen years will receive pension as if he had served thirty years, *i.e.*, thirty-sixtieths, or one-half of his salary and emoluments. But when his term of service reaches forty years he will be entitled to the maximum pension of two-thirds, beyond which he cannot go under any circumstances.

A Poor-law medical officer who falls into age or ill-health, and is incapacitated from duty, is to be entitled to two-thirds of his total emoluments if he has served ten years. A Poor-law medical officer who is incapacitated from work before he has served ten years may be granted (by the Local Government Board) a gratuity on leaving the service not exceeding one month's pay for every year of his service.

We cordially recommend the Bill to the approval of our readers, and are of opinion that, if Parliament assents to it, a just and practical settlement of the question will have been achieved, and a pension approximating to that which the Poor-law medical officer deserves will be provided for him. The dispensary or workhouse doctor will no longer be at the mercy of short-sighted and parsimonious guardians; and the sick poor and the public will be protected against the ill consequences now arising from the refusal of many boards of guardians to grant reasonable retiring allowances.

#### THE GEORGE STEPHENSON CENTENARY.

THE familiarity of the present generation with the principles and applications of steam locomotion, renders it difficult for it to rightly appraise the inestimable advantages conferred on human society by the practical results of George Stephenson's ingenuity. We have grown so accustomed to place dependence on, and to be faithfully served by, steam, that we have ceased to remember the surroundings of him who first reduced to practical tests the theorisings of centuries; and because of the cosmopolitan character of that which has revolutionised the relations of the world, we unconsciously forget in what manner we are indebted for the benefits we enjoy. It would be difficult indeed for the medical profession to gauge aright how much it owes to the modern

applications of steam, or to imagine the condition it would have occupied had the means of inter-communication afforded by the locomotive and marine engine been presented fifty years later than was the case. So tremendous has been the impetus given to scientific discovery by freedom and feasibility of interchange among scientific men, that in admiration of the magnificent consequences following from it, there is danger lest we become ungratefully negligent of the claims on our respect possessed by the father of the railway system, George Stephenson.

It has been truly remarked that a great improvement in medicine or surgery is to be estimated by the rapidity with which it is appreciated by the few, and its merits thenceforward heralded forth by disciples of the original propounder. It may with equal truth be added, that the beneficial influences spread abroad by great reformers in medicine and surgery, are powerful for good in direct proportion to the general comprehension of their nature. How this is affected by steam communication, and how the world has derived advantage by the immediate and widespread appreciation of the epoch-marking changes that distinguish all scientific advance, we have only to examine recent history to see. Not to go far into the past, would antiseptic surgery have so far revolutionised the treatment of wounds as to secure an almost inconceivable decrease in mortality from great injuries, if the means of enlightenment had been of the old slow moving kind? Or again, would the physician's resources have been distinguished by the efficiency and completeness that mark them now—for all they are unsatisfactory at the best—but for the constant exchange of ideas and deductions that is ever proceeding between widely sundered continents. It matters little how we regard the subject; viewed on every side, we, perforce, are driven to perceive our vast indebtedness to the genius that achieved the dreams of many who preceded him, and gave us rapid locomotion.

During the past week there have taken place in various parts of the country the centenary celebration of George Stephenson's birth, and at Newcastle-on-Tyne the occasion has been fitly held to be an appropriate one for assisting a scheme to usefulness of the College of Physical Science located there. There is a close connection between the science of Nature and the science of medicine. So close indeed that we need not be over-sanguine to believe, that the time is not far distant when the dependence of accuracy in medicine on skilled acquaintance with the laws of Nature and the fashion of their action, will receive that recognition, the absence of which is foremost to account for the present unsatisfactory condition of the profession. All, too, that will tend in the direction of assisting so desirable a consummation, ought to receive hearty support, and every effort put forth to bring the two fields of study into closer union, should be met with responsive efforts from those who have the foresight to perceive how much more intimate will be these bonds in the future than they have been in the past.

The hundredth anniversary of George Stephenson's birth was selected by the people of Newcastle as an opportunity of testifying the admiration felt for the genius and works that have perpetuated his name, and made it a household word throughout the world. But with a

wisdom that cannot be too highly commended, the occasion was made to serve the purpose not only of merely paying tribute to the memory of a great man, but to found a "Stephenson" College, in which the study of those forces which Stephenson controlled should help to produce worthy imitators of his achievements. The Colleges of Physical Science that are from time to time formed in our large towns, may be expected to materially affect the future of scientific medicine. The constant cry raised by professors and teachers in medical schools is always against the scientific ignorance of the students who come under them; and undoubtedly it is a fact that in proportion as the practitioner of medicine is well or ill-trained in scientific knowledge, is he a better or a worse doctor. We would, therefore, deem it a subject for congratulation that the number of centres of scientific education is steadily increasing, and especially is it so that these are in most instances up to the present time founded where they will at once and directly affect the study of medicine, by reason of their being situated in near contiguity to already established medical schools.

The memory of George Stephenson cannot be too highly honoured, even by medical men. They owe at least as much as any other class to him. Nor could a more appropriate memorial of him be erected than a college charged with the dissemination of that knowledge, for lack of which he was prevented from perfecting his inventions many long years.

The Stephenson Centenary may not appear to many fraught with the importance it really does possess; and to such persons the association we have striven to demonstrate may be equally hard to discover. This, however, will not remove the burden of our indebtedness, nor will it blind honest perceptions to the magnitude of the benefits conferred on all and every profession by the introduction of steam locomotion. We seek only to show that we are not altogether unmindful of these benefits, and that we are anxious for the closest intimacy between the science of medicine and those other sciences it is so largely dependent on. May the Stephenson College of Science flourish and grow increasingly useful, and may the highest of its services be rendered in connection with the adjoining School of Medicine of Durham University.

## Notes on Current Topics.

### The Army Medical Service.

In another column we reproduce some paragraphs of a "Circular" which, we understand, is being distributed among the medical officers of the army. Whether the grievances expressed in that document are felt generally throughout that branch of the service, or only by a few individuals out of the many, remains to be seen. The circumstance, however, of complaints being made thus early after the recent "concessions" to, and advantages conferred upon, our military brethren, indicates that in reality these concessions and advantages are by no means what theoretically they were expected to be.

The fact is, the scheme of "unification" was pressed on by a section of "reformers" who failed to read, or having read, to profit by the lessons of the past; the

double system as it formerly existed was condemned, chiefly by men whose opportunities were not of witnessing its work upon a large scale, and who were without much actual acquaintance with the nature of relations existing between surgeons and regiments. A spirit of change set in; such men declined to "leave well alone;" the natural results have followed; medical officers having obtained the *divorce* they sought, find they are not happy. But it is not by such means as being designated by other than purely professional titles that their contentment is to be restored. Already distinct departmental rank and title are accorded to each grade; the rank might certainly be designated as "with" that of corresponding executive grades, but the titles already held by army medical officers ought surely to be used by them instead of ignored as they so often virtually are.

It is true that in official documents these titles of rank are observed; but on all other occasions they appear to be dropped. Thus, Surgeon-Major Smith on duty becomes Mr. or Dr. Smith by his own consent when off duty. Not so with his brother in the "combatant" branch. Lieutenant-Colonel Smith retains his title of rank alike whether on duty or not. Why not similarly with medical officers? Does not the remedy lie with themselves?

Unhappily, there is much reason to fear that the general interests of the service have by no means been advanced by this would-be "system," the unsatisfactory results of which upon the officers most directly concerned are set forth in the "Programme" referred to.

#### Royal College of Surgeons of England.

THREE vacancies are declared on the Council of the College, Sir James Paget and Messrs. Walton and Wheelhouse retiring by rotation. Of these Mr. Wheelhouse withdraws altogether from the Council, Sir James Paget and Mr. Walton offering themselves for re-election. The other candidates for the vacant posts are Messrs. Heath, Hulke, Croft, and Sydney Jones, of London, and Mr. Harrison, of Liverpool.

There is but little doubt that the Fellows will return Sir James Paget, whose capacity for administration, and energy in the management of College affairs, is well known. Mr. Walton, also, will probably be returned, as no member of the Council has more regularly attended its meetings, or been more assiduous in the duties of the office. There will be no difficulty in selecting a good third member from among the candidates offering themselves.

It would be useful information to the Fellows if, in future, the number of attendances of each member of the Council could be ascertained, the object of the electors being not so much to confer an honour upon the successful candidate as to elect one who shall do good work. On the other hand, it may not be generally known that, should any member of the Council who has served his term of office be not re-elected at the next election, but should be re-elected at some subsequent election, he must recommence at the bottom of the list, and thus lose the chance of having conferred upon him the honour of Vice-President. It becomes a duty to re-elect a retiring member of the Council to a second term of office unless there is some substantial reason for acting otherwise.

#### Sanitary Assurance Association.

THE first general meeting of the members and the honorary council of the Sanitary Assurance Association since its incorporation was held last Friday, at the offices of the Association, 5 Argyll Place, W. In the unavoidable absence of the president (Sir Joseph Fayrer, K.C.S.I., F.R.S.), Professor Hayter Lewis, F.S.A., vice-president, occupied the chair, and was supported by Sir Richard Temple, Bart., Captain Douglas Galton, C.B., F.R.S., Mr. Romanes, F.R.S., Mr. George Aitchison, A.R.A., Professor Corfield, M.D., Mr. John Whichcord, F.R.I.B.A., Mr. Mark Judge, and Mr. H. Rutherford. Professor Corfield (chief sanitary officer) and Mr. Judge (surveyor) related to the meeting the progress of the Association, and reported on the work of sanitary inspection that had been done. The property which had been placed on the assurance register varied in value from houses rated at £60 a year—in which the total fee to subscribers for report, supervision of work, and certificate, is two guineas—to houses rated as high as £700 a year, with proportionately increased fees. The Association undertakes the inspection of the smallest class of property, and no fee is charged to subscribers for a single house rated at £20, while the fee is only half a guinea for houses rated at £40. In the discussion which followed Sir Richard Temple, Captain Douglas Galton, and Mr. Whichcord spoke strongly in support of the objects of the Association, and the council were requested to take steps to make the Association as widely known as possible, and particularly to call the attention of the proprietors of large building estates to the advantages which would accrue if the certificate of the Association was made essential to the granting of leases. Professor Hayter Lewis in acknowledging a vote of thanks for presiding, said he hoped the council would have still greater progress to report when the time for the annual meeting came round. He trusted that speculating builders would soon recognise the value of the certificate of the Association, for there could be no doubt that houses certified as in a satisfactory sanitary condition by the Association would be of greater value in consequence.

#### Presentation to an Asylum Medical Officer.

ON the occasion of the departure of Dr. Connolly Norman, Assistant Resident Medical Superintendent to the Monaghan District Asylum, the esteem in which he is held by his co-officers very fittingly and spontaneously manifested itself in a presentation which was made by the officers, attendants, and nurses of the Asylum. The presentation consisted of a gold lever hunting watch. Dr. Roberson, the Ven. Archdeacon Stack, D.D.; A. K. Young, Esq., J.P.; Dr. Norman and all the attendants and nurses being present at the ceremony. The watch was presented in the name of the attendants by the house steward, who said that he never before witnessed such alacrity as was displayed by the attendants in contributing to the cost of the presentation.

Dr. Norman, in returning thanks, expressed the sorrow he felt at leaving a place where so many had been so kind to him, and said that he would ever prize their valuable present with an affectionate remembrance of those who had presented it to him.

### The New Infirmary for St. Marylebone.

THE vast building, which is to hold 700 sick poor, is rapidly being prepared to receive inmates by the 29th inst., when their Royal Highnesses the Prince and Princess of Wales will officially declare the building open. About 1,400 invitations will be issued on the occasion. The working committee consists of the following guardians:—Mr. Edmond Bulnois, J.P., chairman; Dr. J. McGrigor Croft, formerly Staff-Surgeon to Her Majesty's Hospitals; Lieut.-General H. Lynedoch Gardiner, J.P., Equerry to Her Majesty; Admiral Oliver; Captain Lealie; Messrs. Daniell, Debenham, and Robbins. The organisation of the staff, male and female, for so extensive an establishment, together with the furnishing of the same at a cost of £10,000, arranging the sick wards, &c., has been, and still is, a work of much time and labour to most of the committee, and will, no doubt, be appreciated by their Royal Highnesses on the day of the opening.

### Union Hospital Clinical Recognition.

THE following resolutions were adopted at the conference, at the Hibernian Hotel, Dublin, on Monday, 6th June, Dr. Adrien in the chair:—

1. That a standing committee be appointed to take all the necessary steps to carry their application to a successful termination.

2. That Union Hospital physicians are requested to unite as one man, and prove by their attitude towards those ready to support their just claims how deeply they desire to see those claims recognised.

3. That they are requested to use every opportunity for bringing under the notice of the senators in their respective neighbourhoods the grounds on which they base their claims.

4. That the memorial now read be printed and forwarded to the senate, and that Drs. Daly, Adrien, Laffan, and Kenny do constitute the deputation for the purpose of seeking an interview with that body. Eighty-two physicians have already signed the memorial, and numerous letters promising the most earnest support were received.

Dr. O'Reilly (Lismore) was called to the second chair. Drs. Daly and Kenny acted as secretaries. The meeting then broke up.

The following were named the standing committee:—Drs. Smith (Belfast), Baggot (Enniskillen), Brown (Derry), Ryom (Baillieborough), Bradshaw (Carrick-on-Shannon), O'Farrel (Boyle), Macaulay (Ballina), Shanley (Athlone), Daly (Meath), Adrien (Drogheda), Kenny (Dublin), Moorhead (Tullamore), O'Neil (Athy), Barry (Limerick), Cremen (Cork), Laffan (Cashel), O'Reilly (Lismore), Cullenan (Ennis), Hayes (Rathkeale), Holland (Dungarvan), O'Reilly (Trim), &c.

### Death of M. Littré.

M. LITTRÉ, the famous French lexicographer, died on Thursday week in Paris, at the advanced age of 80 years. The work done by M. Littré had such value for all scientific students and scholars, that he is not likely soon to be forgotten, and his *magnum opus* the dictionary, will ever remain in testimony of his indefatigable exertions. This work was commenced in 1863, and completed in 1872.

### The Old English Fair.

THE Old English Fair held at the Royal Albert Hall in aid of the Chelsea Hospital for Women has been attended with unqualified success. An amount not falling short of £5,000 will, as a result of it, be credited to the funds of the charity, the highly deserving nature of which has been thus fittingly recognised by the immense number of visitors to the bazaar.

### Hospital Reform.

THE adjourned meeting of the Metropolitan Counties Branch of the British Medical Association took place on Friday last at the rooms of the Medical Society of London, Dr. Habershon, the President of the Branch, occupied the chair. There was a very large gathering of members, and a very animated discussion took place on the report brought up for adoption by the sub-committee appointed to report on the question of Hospital Reform. The recommendation that an influential deputation of the Branch, accompanied by men who have practical acquaintance with hospital administration and its deficiencies, be deputed to urge upon the Home Secretary the early appointment of a Royal Commission, to investigate and report upon matters of hospital reform, was carried by a very large majority. The report was forcibly drawn and well supported by facts set forth in tables and statistics, contained under the following heads:—

1. That the present system of hospital administration is attended with many anomalies which call for public inquiry.

2. That in the metropolis especially the hospital accommodation is imperfectly distributed, and, in many districts, is altogether inadequate.

3. That the unsatisfactory condition of the present out-patient system of our large metropolitan hospitals demands reform.

4. That the workhouse infirmaries as at present administered do not render such services to education and medical science as they might.

5. That it is desirable that every hospital and medical institution intended for the relief of the suffering poor should be administered by a board of management, subject to periodical election by the governors, upon which board the medical staff of the institution should be adequately represented.

6. That a public audit of the accounts of all such institutions is needed, to secure a right distribution of medical relief, and a more economical expenditure of the funds entrusted to the boards of management.

7. That the importance of medical education, and of adequate training of the members of the medical profession, requires an *intelligent recognition* of the relations of the hospitals to their medical schools, to insure an improvement in such relations.

8. That the absence of organisation and combination amongst the medical institutions throughout the country materially lessens their usefulness.

9. That in the administration of the wards, so far as it affects the treatment of patients, and especially in the management of the nursing arrangements, the medical staff shall have an authoritative voice.

10. That in order to ascertain fully the needs of the

suffering poor throughout the country, and the means at present available for their relief, especially with the view of obtaining reliable data upon which to base the needful reforms, it is most desirable that a Royal Commission should be appointed.

#### Brains versus Flesh.

UNDER a somewhat novel guise, the old question opened first at Guy's Hospital, and repeated at several other places since, has cropped into view at Bristol. It is in all, a question of brains against flesh, and, as in other cases, it seems as though the result at Bristol is to be in favour of flesh also. The governors of the Bristol General Hospital are arrayed in fleshy strength against the medical and surgical staff on the subject of flooring for the wards. This, in opposition to scientific authority, was formerly made of *cement*, and now, after twenty years use, it calls for renewal. Experience has proved what science averred, that, namely, cement is wholly unfit for flooring where disease is constantly present; that it forms a nidus for infection; that it is calculated to retard recovery by its chilling influence; and, in a word, is of all substances that least adapted to the purpose it has been made to fill. Notwithstanding the lay governing body of the hospital is almost united in opposition to the feeling of the educated officials, and by the weight of its fleshy mass decides to ignore the demand for wooden flooring in order to renew the miserable cement. Anything more entirely in keeping with the wooden obtuseness characteristic of lay opinions generally on matters of scientific importance it is impossible to conceive. It is right to say, however, that the chairman of the board, intelligent enough to perceive the utter brainlessness of his *confrères*, has declined to share the responsibility incurred by rejecting the suggestion of the medical staff, and has resigned his post. Perhaps, bye-and-bye, when the Bristol School of Science has had time to extend the influence exerted by scientific knowledge on the intellect of the fleshy members of controlling committees, we may hopefully look for a better appreciation of the truths involved in discussing sanitary measures. At present it seems a mere contest between brains on one side, and dead weight on the other; and, so far, weight wins.

#### The Oxford First M.B.

BY a decree passed without opposition at Oxford on June 7 candidates who in future enter for the 1st M.B. examination of that University, and who have previously obtained honours in the School of Natural Science, will not be required to pass again in the subjects of chemistry, mechanics, and physics. These subjects, it must be said, are included in a preliminary honour examination which every candidate for natural science honours must succeed in passing before admission to the final test, which may be in biology, chemistry, or physics. The examination, moreover, is of considerable difficulty, and it has long been felt to be a grievance that men who have already shown they are grounded in these sciences should be compelled to go through an examination in them again. The decision is a wise one in all respects, and it may be expected to increase the number of those who seek the Oxford degree, but have been hitherto deterred from doing so in some measure

by an unwillingness to devote time to the subject already undertaken.

#### Professor Hutchinson on Heredity.

ON Monday afternoon last, Professor Jonathan Hutchinson, F.R.C.S., delivered the first of a series of six lectures at the Royal College of Surgeons of England, on Heredity and Transmission in Health and Disease. In this lecture Mr. Hutchinson dwelt on the importance of a careful study of the facts presented in nature bearing on heredity, and proceeded to define the terms employed in speaking of the subject. He next enumerated and explained the suggested mode of action of the laws by which transmission from parent to offspring is governed; and, in conclusion, expressed the conviction that each parent was equally concerned in the matter, the attempts to attach greater or less importance to the part played by one or other being weak, and resulting in no good results.

#### International Medical Congress.

THE Executive Committee of the International Medical Congress are very desirous that all intending subscribers to the expenses should, without delay, send in their subscriptions, as the lists are being completed. It is requested that all who may find it convenient should call at the Royal College of Physicians to register their names as Members of the Congress, and pay the membership subscription to Mr. Garner, Bedell, as a preliminary list will presently be printed.

#### The Hudson Scholarship.

THE first annual distribution of the Hudson Scholarship prizes took place in the theatre of the Adelaide Hospital, Dublin, on Friday, June 3. Dr. George Johnston, the President of the King and Queen's College of Physicians, presided. These prizes consist of a scholarship for one year of the value of £30 accompanied by a gold medal, and a prize of £10 accompanied by a silver medal. The foundation consists of a donation of £1,000 by Mr. Henry Hudson, of Chester, brother of the late Dr. Alfred Hudson, which was given to the latter two years before his death for the purpose of being applied in any way he thought fit. He handed over the money on a perpetual trust to the Board of the Adelaide Hospital, for them to apply it in such a manner as they thought would be best calculated to advance the science of medicine; and the Board founded the prizes in question. The winner of the scholarship and first medal was Mr. Edward Gordon Hull, and the prize and second medal were taken by Mr. Frederick William Elsner. On the occasion of the award of the scholarships, Dr. James Little, one of the physicians to the hospital, gave an outline of the career of the late Dr. Hudson, detailing some of his many struggles to rise to eminence in his profession, and pointing him out as an example for those to follow who were about to enter the medical profession.

#### Death of Dr. Brice, of Armagh.

THIS gentleman—one of the oldest medical denizens of Armagh—died last week. Some time ago he met with an accident in his own house, by falling off a ladder, since which he never enjoyed health. Dr. Brice was a licentiate apothecary of over fifty years' standing.

### The "Unqualified Assistant" System in its Relation to Death Registration.

At a recent inquest held at Birmingham, the borough coroner is reported to have declared that "he had every reason to believe in the prevalence of systematic fraud in Birmingham in connection with the registration of deaths." In the case under investigation it transpired that a local medical practitioner gave a certificate of the death of an infant whom he had never seen alive. As a matter of fact, he really knew nothing at all about the cause of its decease other than what he was told; and yet it would appear that he signed the certificate without the slightest demur, thereby enabling the body to be buried without further inquiry. This, we need not say, is no new thing, but the coroner did well to comment severely upon it, if the certificate was filled up so as to imply that the child had been attended by the medical man who signed it.

### Murder of a Medical Practitioner.

A DISCOVERY which has caused considerable excitement was made last week at Swansea. The body of Dr. Sheppard, a prominent local medical man, was found in one of the public streets at 3, a.m., stabbed to the heart. A sailor's knife, covered with blood, was lying near the corpse.

### Queen's University in Ireland.

THE June Medical Examinations of the Queen's University commenced on Monday, the 6th inst., and will end on Friday, the 17th inst. The meeting of the University to confer degrees will be held in Dublin Castle on Monday, the 20th inst.

THE twenty-fifth anniversary of Dr. Rudolf Virchow's appointment as Professor in the University of Berlin is to be celebrated on October 13th.

ABOUT forty cases of scarlet fever having recently occurred near Keswick, Dr. Robertson, the medical officer for Cockermouth, states that the disease has been traced to a dairy from which all the persons attacked obtained their milk. There had been a case of fever at a house next to the dairy.

DR. SAYRE, of New York, well-known in this country for his treatment of spinal curvature, has had an action brought against him to recover 25,000 dols. damages for alleged unskillful treatment. We are happy to record the fact that proof was entirely negatived, and a verdict given for our *confrère*.

THE Lords of the Admiralty have granted the use of a second screw frigate to the Metropolitan Asylums Board, to be used as a hospital ship for small-pox cases, one having been found insufficient for the number of cases in the metropolis. The vessel is at present attached to the Medway Steam Reserve.

SUNDAY next has been fixed for Hospital Sunday in London, when the annual collections will be made in most of the places of worship in aid of the Fund. We understand that the Lord Mayor and Sheriffs will attend

officially the service at Westminster Abbey in the morning, and St. Paul's Cathedral in the afternoon.

At a meeting of the Council of the Royal College of Surgeons of England, held on Thursday last, Professor John Marshall, F.R.S., F.R.C.S., was elected the representative of that College in the General Council of Medical Education and Registration, in the vacancy occasioned by the resignation of Sir James Paget, Bart., F.R.S.

WE are glad to see that the Charity Organisation Society has taken a step which must command general approval. Following up its efforts last year for the establishment of convalescent homes, the society has arranged with several ladies to take into their own houses in the country, girls and women of respectable character who require change of air and good food.

ONE would have supposed that a policeman finding a lunatic at large, or under insufficient guardianship, was doing a good act by taking him in charge and conveying him to the workhouse. That, however, is not the opinion of the Lunacy Commissioners. A policeman who had taken this view of his duty was prosecuted the other day by the Commissioners before the Sunderland magistrates, and fined a shilling for effecting an illegal apprehension.

THE annual rates of mortality last week in the principal large towns of the United Kingdom per 1,000 of the population, were—Brighton 12, Wolverhampton 14, Plymouth 15, Leicester 16, Bradford 17, Hull 17, Leeds 17, Norwich 17, Birmingham 17, Nottingham 19, Oldham 19, Salford 19, London 20, Edinburgh 20, Newcastle-on-Tyne 21, Liverpool 21, Portsmouth 22, Sheffield 22, Glasgow 22, Sunderland 23, Bristol 23, Manchester 25, and Dublin 26.

IN the principal foreign cities the rates of mortality, according to the latest official weekly return, were in—Calcutta 31, Bombay 34, Madras 49; Paris 32; Geneva, 14; Brussels 22; Amsterdam 29, Rotterdam 22; The Hague 25; Copenhagen 23, Stockholm 22, Christiania 19; St. Petersburg 61; Berlin 22, Hamburg 24, Dresden 20, Breslau 35, Munich 33; Vienna 34; Buda-Pesth 40; Rome 24, Naples 33, Turin 23; Alexandria 33; New York 35, Brooklyn, 26, Philadelphia, 22, Baltimore, 28 per 1,000 of the various population.

THE mortality last week from diseases of a zymotic character showed the country to be in a most favourable condition—excepting the large number of deaths in London from small-pox, a remarkably healthy bill is observable throughout. Of these diseases, measles showed the largest proportional fatality in Bristol and Sheffield; scarlet fever in Edinburgh and Wolverhampton; and whooping-cough in Dublin, Leicester, Sheffield, and Birmingham. The 14 deaths from diphtheria included 9 in London and 3 in Portsmouth. Small-pox caused 90 more deaths in London and its outer ring of suburban districts, one in Liverpool, one in Manchester, and one in Newcastle-on-Tyne; but no fatal case of this disease was registered in any of the other large towns.

## Scotland.

(FROM OUR NORTHERN CORRESPONDENT.)

**UNIVERSITY OF EDINBURGH BUILDINGS EXTENSION FUND.**—The Lord High Commissioner, the Earl of Aberdeen, before leaving Edinburgh at the termination of his official duties, intimated his intention of subscribing one hundred guineas to the above fund.

**OPIMUM POISONING IN EDINBURGH.**—During last week there were three or four cases of accidental or suicidal poisoning by opium taken to the Royal Infirmary. Among these one case proved fatal.

**EDINBURGH DISPENSARIES.**—The practical pharmacy department at these places of instruction appear to stand in need of some little improvement. No labels are placed on the patients' bottles, and the dispenser at one of them will not condescend to give even a verbal direction as to the manner in which the medicine is to be taken. We know of one case, unfortunately not the only one, where a patient used as a liniment a mixture containing iodide of potassium and infusion of quassia, and complained that he derived no benefit and that it appeared "very cold." A liniment had, at the same time, been ordered, but for some reason best known to the dispenser, it had not been given, or the transposition might have been serious, to say the least of it. The cost of labels is not great, and would ensure in some measure the protection of the patient, a verbal direction to take a teaspoonful might lead to fatal results if the patient took a table-spoonful of the medicine instead, under the impression that such had been ordered. A printed label would remove this danger.

**THE "FELLOWSHIP DISTINCTION" OF THE EDINBURGH COLLEGE.**—In consequence of certain misstatements and misapprehensions regarding the present system of admission to the "Fellowship of the College" a "statement" has been put forward in which considerable anxiety is shown to convince the medical world that the late strictures of the press are beneath contempt, and that the "statement" is not intended as an answer to the anonymous scribbles in the medical journals. There is the usual amount of special pleading which always characterise the "deliverance" of advocates on the weaker side. For instance, we are seriously informed that the "examination test" of the London College "has not produced any whose fame has eclipsed that of Cooper, Brodie, Bell, or Lawrence, and others, who, as simply members of the London College, shed lustre on the profession of the preceding generation." The logical result of such enlightened reasoning is, that all tests and examinations are useless, for they have not produced one whose fame has eclipsed that of the physician of Cos. Sir Trevor Lawrence should have thought twice before trying to induce Parliament to demand an examination which, had it been in vogue some years ago, might have eclipsed his father's fame. Whether severe examinations improve or injure men is not the question at issue, but the public have a right to demand that men with high sounding titles should give some guarantee that they are merited.

**DISPUTED AFFILIATION BY A "MEDICAL PRACTITIONER."**—Samuel Levenston (M.D. Univ. Glas.), of too well known antecedents, and whose name was lately removed from the "Medical Register," raised an action in the Sheriff-Court, Greenock, some time ago, against Solomon Alexandra Levenston, residing there, asking the sheriff to interdict the defender from publishing that he was the son

of the pursuer. At the time the application was made, Sheriff-Substitute Smith granted interim interdict. The defender had been in the habit of advertising as a "medical practitioner;" that he was the son of Dr. Levenston, of Glasgow; and was now in medical practice in Greenock. Among the pleas stated by the defender was that the pursuer's real name was not Levenston, but Jacobs. The sheriff-substitute has just issued an interlocutor, in which he recalls the interim interdict, and dismisses the action, and finds the defender entitled to expenses. In his note his lordship says that the plea of the pursuer's real name being Jacobs is of no use. He notices that there is a classical authority to the effect that "a man may call his house an island if he likes." So H. Jacobs might transmute himself into Levenston if he thought proper. The plea, therefore, seemed unsound. But the pursuer's complaint was that the defender had advertised himself as the "son of Dr. Levenston." Glasgow is a large place, and there might be many other people (doctors or not doctors), besides the pursuer, who had there acquired by right of birth, or by their own approbation, the name of Levenston which seemed to be a favourite one with advertising medical practitioners. The pursuer, before he could ask for proof of his averments, must be in a position to state that the "son of Dr. Levenston" necessarily means "son of Samuel Levenston, Doctor of Medicine, 6 Hope Street, Glasgow," pursuer of the present action. Few people would be proud of the relationship claimed by the Greenock "medical practitioner;" and a fair estimate of the man may be reached by Dr. Samuel Levenston's disowning him. Dr. Levenston seems to recognise that the line must be drawn somewhere, and he emphatically draws it at such sons.

**HEALTH OF EDINBURGH.**—For the week ending with Saturday, June 4th, there were 85 deaths in Edinburgh, and the death-rate was 20 per 1,000. Only one death from fever was reported, and that was in the New Town. The southern suburbs were entirely free from zymotic mortality.

**THE GLASGOW DEATH-RATE.**—The deaths in Glasgow for the week ending with Saturday, the 4th June, were at the rate of 27 per 1,000 per annum, as compared with 22 in the previous week, and 23, 22, and 27 in the corresponding weeks of 1880, 1879, and 1878.

**UNIVERSITY OF EDINBURGH—DOBBIE-SMITH PRIZE IN BOTANY.**—Mr. Thomas Smith, L.R.C.S.E., Heriot Hill House, Edinburgh, has intimated his intention of presenting a sum of £150 to the University for the purpose of founding a prize for the encouragement of the study of botany in memory of his late wife, who was a devoted student of that subject. The prize is to be a gold medal of the value of £10, to be called the Dobbie-Smith medal, to be awarded every second year, and to be open to all matriculated students of the session in which the medal is awarded. The subject of competition to be always a botanical subject, and to be announced at least eighteen months before the date fixed for receiving essays. The subject of the first competition to be an essay "On the geographical distribution of Algae," accompanied by a collection of Algae from the Firth of Clyde or from the Firth of Forth.

**THE COMBE LECTURES.**—In the lecture of the 7th inst., which was delivered before a large audience in the Upper Hall of the Training College, Edinburgh, Dr. Wilson dealt with the constituent elements of food, in reference to their comparative value as means of nutrition. A healthy adult, he said, should consume per day 4½ oz. of nitrogenous matter, about 3 oz. of fat, 14 oz. of starches and sugars, and 1 oz. of

minerals. This amount of nourishment might be obtained by eating 16 oz. of meat, or its equivalent, 19 oz. of bread, and 3½ oz. of butter; while water should be absorbed to the amount of 52 oz. The amount of food required varied with the conditions under which the person lived. Thus, for a man in idleness, 2·67 oz. of nitrogenous, and 19·61 oz. of carbonaceous matter might suffice; but for one engaged in ordinary labour, the proportions should be 4·58 of nitrogenous, and 29·24 of carbonaceous; and for one at hard labour, 5·81 of nitrogenous and 34·97 of carbonaceous. It was stated that 2½ lb. of meat and bread would afford as much nourishment as 10 lb. of potatoes; and the lecturer remarked that we could not have a contented people where potatoes formed a large proportion of the dietary. In regard to tea, again, regret was expressed that the poor should set so much store by an article which contained no flesh-forming elements, while cocoa, with bread and milk, formed a dietary on which a large amount of work could be done. The place of tea and coffee, it was explained, was that of aids to nutrition and preventers of waste. As to alcohol, the lecturer remarked that much of its action on the body was yet a sealed book. This much had been ascertained, that alcohol was positively injurious to the young and growing body. The healthy adult had no necessity for it; but medical men had to consider alcohol from this point of view, that human life was not regulated by a biological rule of three. There were differences of constitution, and alcohol might in some cases, be useful as a digestive aid. He did not say that in all cases that held good, but he was very far from taking up the position that there was no good in alcohol and no use in wine. He quite sympathised with the temperance agitation as regarded too many of the drinking customs of this country, which had neither physiology nor common sense on their side. Alcohol should only be taken along with food, and in that case it might have dietetic uses. Proceeding to speak of the process of digestion, the lecturer began with mastication, closing for the day with an account of the structure and mode of growth of the teeth.

## Correspondence.

### SPONTANEOUS COW-POX.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—As even Dr. Carpenter (who believes in the fundamental identity of vaccinia and variola) now suggests having recourse again to the cow for an entirely new supply of "lymph," to replace the present deteriorated stock, I presume that there is little doubt that such an attempt will be made on a considerable scale.

The question now arises whether it would be best made with a foreign or native stock? If a foreign stock is selected it is evident that much must be taken upon trust of which the fullest evidence is desirable.

My own faith in the virtues of either is limited; but, being patriotic, I like to give the preference to the native article; and I, therefore, place at your disposal the information recently sent to me from the county Elgin, N.B., where, it appears, the disease vaccinia is by no means extinct, and every year it breaks out on some of the farms.

Let me suggest that such "lymph" be fairly tried, and a record kept of its effects carefully separating such record from that of persons vaccinated with "lymph" from other sources.

The extreme activity of "lymph," which has not been humanised by passing through some human beings, will always constitute a difficulty when the question of compulsion has to be considered. But the alternative of having to run risk, now acknowledged by all parties to exist (and

which is enough to make the firmest believer shudder), absolutely leaves no option to those who have to administer the law. Animal lymph must be provided for the whole people, or the principle of compulsion must be finally abandoned.

I am, Sir,

Your obedient servant,

Upper Norwood, S.E., EDWARD HAUGHTON, M.D.  
28th May, 1881.

### A "FUNIS REPLACER."

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Arnold and Sons, London, have made for me a "Funis Replacer." The accompanying drawing will show what it is like. It is made of the same material as a gum elastic catheter or a rectal bougie. It is sixteen inches long, slightly flattened, elastic, but sufficiently strong to be pushed up into the fundus of the uterus during labour. It is bifurcated at one end, having two digits each about three-quarters of an inch long. Into the notch between these it is intended to hook the funis in case of prolapse, and then to carry it up past any presenting part to the fundus, and there to leave both instrument and funis until they are extruded with the infant. The instrument will be found easy of application as it is strong enough to manipulate with, and the notch is so deep and wide as to render it easy to seize and hook the prolapsing funis.

Cases of prolapse of the funis are not very common, but generally the result is unfavourable. This instrument will be found very successful in cases where the prolapse is recent, and in which the pulsation still continues. I have not met with a case just suited to confirm this statement, but I have used it in a case in which the prolapse had been for a great many hours, and in which the pulsation had ceased, and consequently the child had perished. I satisfied myself, however with the practicability of using it in proper cases. I readily hooked the funis, and carried it up past the presenting part (in this case the nates), cautiously pushing it along in the intervals of the pains until it reached the fundus. I did not withdraw the instrument, but allowed it to be expelled with the fœtus. The instrument is not sufficiently thick to lessen the diameter of the pelvis, and will not be found to interfere with the ordinary progress of labour.

I am confident if this instrument is used at an early stage, before pulsation has ceased, it will be found to save the lives of many infants, and I recommend it to the notice of accoucheurs in large practice, and to the masters of lying-in hospitals; and I will feel obliged if anyone who has used it will publish the results.

I remain, dear Sir, yours very truly,

WILLIAM WAUGH LEEPER, M.D.

Loughgall, Armagh, June 10th, 1881.

## Literature.

### THE FACTORS OF THE UNSOUND MIND. (a)

THE amendment of the law which Dr. Guy aims at is the abolition of the cumbersome, illogical, and irrelevant system of procedure at present in vogue when the plea of insanity is raised in the English courts, and the substitution thereof of the simple and direct question, "Is the accused insane or is he not?" This question would be decided on the evidence of experts appointed for the regular investigation of such affairs, and if necessary the accused would be committed for a period to a public institution, where his mental condition could be closely and continuously examined by physicians skilled in this special branch of medicine. There can be no reasonable

(a) "The Factors of the Unsound Mind," with Special Reference to the Plea of Insanity in Criminal Cases, and the Amendment of the Law. By William A. Guy, M.B., &c.

doubt that this system long ago adopted in France and Germany would be far more definite and scientific in its results, and therefore far more satisfactory to the ends of justice than the present English happy-go-lucky jumble of antiquated law and inexact medicine. We cannot agree so entirely with Dr. Guy in some of his other conclusions. He has pointed out very happily the similarity of the various factors of unsound mind to each other severally, but we think he carries analogy too far when he insists that an uncontrollable impulse and an hallucination, or, as he calls it, an illusion of the senses, are equivalent phenomena; for, granting that there is a function of volition comparable to that of sensation (a fact by no means proved), it still remains evident that disorders of the former imply a much profounder nervous lesion than those of the latter. Sensation is the simplest of all psychical operations in the normal state; volition, on the other hand, which Hobbes has called "the last appetite in deliberating," is normally the most complex, and the tendency of the evidence which disease affords is to prove that in morbid states this relation is unaltered. The point is not a mere metaphysical subtlety, for behind it lies the deep question, "Are we justified in holding a man exempt from the consequences of an act alleged to be committed under the influence of an uncontrollable impulse, when there is no other evidence of mental alienation than the act itself, and the manner in which it was performed?" Now it is well known that sensory hallucinations occasionally occur in persons otherwise apparently in perfect health. In these cases they are corrected by the other senses and the judgment. The reaction of the organism as a whole is healthy, in spite of a diseased sensation. But the mere fact that an impulse is uncontrollable (a fact denoted by the common phrase, insane impulse), indicates a deep implication of those higher functions of judgment and comparison which serve in health to, as it were, inhibit the action of the lower functions. It must be remembered that impulses of a "spontaneous" and unaccountable nature are not unknown among the sane, but are by them controllable. Even madmen do not at all times and places yield to their impulses. Therefore in cases where uncontrollable impulse exists, we are prepared to find other traces of grave deviation from mental health. Clinical experience corroborates this view. Such impulses are common as post-epileptic or ante-epileptic phenomena, where the whole field of consciousness is clouded. They are also not infrequent in the earlier stages of those cases of mental degeneration mostly associated with hereditary taint, which come on slowly without definite exciting cause, and are usually quite incurable. In individuals thus afflicted there is always a profound morbid alteration in the affective or in the intellectual faculties, or perhaps in both, though the alteration may not be obvious without careful examination. We therefore demur to the doctrine that uncontrollable impulse can be inferred merely from the assertion of the accused and the nature of the deed, and we hold that to accept such a plea would be not only socially unsafe, but also scientifically incorrect.

Further, with regard to the varieties of hallucinations we may point out a distinction that seems to have escaped Dr. Guy. When a man imagines he sees a friend and steps up to him with out-stretched hand, he has an hallucination of vision, but he acts in a strictly rational manner. On the contrary, when, as in a case cited, a man hears "a voice," saying "throw yourself into the river," and when he obeys the "voice," there is something more than an hallucination of hearing. His obedience to the command proves that reason has abdicated its sway. It may not be irrelevant to note that hallucinations of vision are common in various forms of mental aberration, and are not of specially evil omen, while a very unfavourable prognosis may be generally given in cases where hallucinations of hearing exist.

On the whole, though we have been compelled to record our dissent from Dr. Guy in some particulars, we must express our opinion that his last work is not unworthy of its illustrious author. It is conceived in a spirit of rational humanity, without any trace of foolish sentimentalism. It is most agreeably written, and contains much ingenious reasoning, and a large store of carefully-arranged facts not easily obtainable anywhere else in so compact a form.

#### THE INFECTIOUS DISEASES (IRELAND) BILL.

OUR readers are already aware that when the Irish Medical Association took the votes of the medical practitioners of

Dublin upon the proposition that the attending physician should give written notification of the occurrence of every case of infectious disease which came under his notice, the answer of the profession was—by a majority of two to one—adverse to any such proposal. The advocates of such a system of notification endeavoured to explain this vote upon the hypothesis that those who omitted to give any reply were all of their opinion, and by saying that an a plebiscite of the metropolitan practitioners did not represent the views of the profession throughout Ireland. Since then the general meeting of the Irish Medical Association has—after a very prolonged debate and despite the aggregate eloquence of the most influential notificationists in Ireland—again condemned the system advocated by them. This redoubled expression of disapproval, however, does not seem to have convinced the champions of Mr. Gray's Bill that the profession will have none of the measure, for we find the *Dublin Express*—the journalistic exponent of notification comforting its party with the assurance that majorities are not infallible, and that the voice of the profession in Ireland had not yet been fully heard on the subject.

Lest any doubt might remain as to the feeling of medical men in Ireland respecting these proposals, we have ourselves, within the last week, afforded them an opportunity of giving their vote explicitly for or against the principle of Mr. Gray's Bill. We issued circulars to 1,300 medical men whom we believed to be in actual practice in Ireland, and to them we submitted the following questions:—

1. Do you approve that the physician shall be compelled to notify, *in writing*, the occurrence of every case of infectious disease?
2. If not, do you approve of proposed amendment, *i.e.*, that the custodian of the patient or householder should be *alone* responsible to notify?

Up to Monday morning we have received 692 returned circulars, of which the following is an analysis:—

Against written notification by the physician in any form (No! to Question 1) ... ..	668
For direct written notification by the physician to the sanitary authority (Mr. Gray's proposal) ... ..	5
For <i>indirect</i> written notification, <i>i.e.</i> , by the physician to the custodian of the patient, and by the latter to the sanitary authority ... ..	8
For the proposal that the custodian of the patient or householder should <i>alone</i> notify (yes! to question 2) ... ..	608
Against such proposal ... ..	13
No reply to such proposal ... ..	44
Dead letters and blank circulars ... ..	15

Thus, by a vote of more than fifty to one the profession throughout Ireland repudiates Mr. Gray's Bill, and protests against the function which it proposes to burthen them with,—while out of 1,300 working practitioners only five have as yet recorded their approval of the measure.

We have preferred to publish at once the analysis of replies sent us within a single week rather than allow the present interest in the subject to pass away while we waited for further returns of our circular. As, however, we desire to make the vote of the profession as complete as possible, we earnestly request that those who have not yet sent back their replies will do so at once, stating without hesitation their views, no matter whether they hold our opinion or the contrary.

This plebiscite, we believe, finally decides the question as to the attitude of Irish medical men towards compulsory notification, and it certainly ought to convince the advocates of that policy that if they are to have their way it must be by the summary process described by one of their speakers as "ramming notification down the throat of the profession." There is much candour in this definition

which truly expresses the policy of the notificationists from the first, though they felt it to be diplomatic to try whether the dose could be sufficiently disguised to make it acceptable to Irish doctors. Hence all the suggestions about indirect notification and a half-crown fee. Now that the profession has definitely and emphatically declined the dose, we shall see whether the "ramming" process will be persisted in. We rather think not.

**Royal College of Surgeons of England.**—The following Members having passed the required examination for the Fellowship on May 26th, 27th, 28th, and 30th, were, at a meeting of the Council held on June 9th admitted Fellows of the College:—

Bowly, Anthony Alfred, Warrington Crescent; diploma of Membership dated July, 1879.  
 Boyd, James Stanley Newton, M.B. Lond., Huntley Street, Bedford Square; diploma July, 1878.  
 Burton, Samuel Herbert, M.B. Lond., St. Giles Street, Norwich; diploma January, 1876.  
 Carter, Frederick Healer, Upper Tooting; diploma July, 1875.  
 Crew, Wm. Thomas, L.R.C.P. Lond., Macclesfield; diploma July, 1879.  
 Heath, William Lenton, The Plains, Totnes; diploma July, 1877.  
 Pollard, Bilton, M.B. Lond., West Dulwich; diploma November, 1879.  
 Sheppard, Charles Edward, M.B. and L.R.C.P. Lond., Addison Gardens; diploma July, 1877.  
 Symonds, Charters James, M.D. Lond., St. Thomas's Street, Southwark; diploma July, 1876.  
 Turner, Edward Beadon, L.R.C.P. Lond., Sussex Gardens, Hyde Park; diploma July, 1877.  
 Wadham, Frederick, L.R.C.P. Lond., Horley; diploma Nov. 1878.  
 Williams, William Roger, L.R.C.P. Lond., Enfield; diploma April, 1877.  
 Williamson, Robert Isherwood, M.B. Oxon., L.R.C.P. Lond., Ripon, Yorkshire; diploma April, 1879.  
 Willis, William, M.D. Edin., Monmouth; diploma July, 1868.

Also passed, but was not a member of the College:—  
 Reid, Robert William, M.D. Aberdeen, Nottingham Place, Regent's park.

Two other candidates passed the examination, but, being under the legal age (twenty-five years), will be admitted Fellows at a subsequent meeting; and ten candidates failed to reach the required standard, and were referred for one year's further professional study.

## NOTICES TO CORRESPONDENTS.

**NOTIFICATION OF INFECTIOUS DISEASE IN IRELAND.**—Medical practitioners who have received the Circular from the *Medical Press* are earnestly requested to return it *without delay*.

**DISINFECTIO.**—Sanitas asks: Is it the duty (on being so required by a Board of Guardians) of a sanitary medical officer of a district to disinfect without fee or reward any house in which a contagious disease has been? I am led to ask the question as I have known some cases where the medical officer has been compensated for such services.

[It is the duty of the medical officer simply to report and recommend disinfection. The work is carried out by the sanitary sub-officer, and neither he nor the medical officer is entitled to any extra fee.—ED.]

**AN ANXIOUS INQUIRER.**—If our correspondent will refer to the notes under the heading of "France" he will find an answer to his query from "Our Special Correspondent." The *Académie de Médecine* have, after much anxious inquiry and discussion, decided that compulsory vaccination should become law for France, and that re-vaccination should be encouraged.

### RECOVERY OF FEES.

To the Editor of the *MEDICAL PRESS AND CIRCULAR*.

SIR,—Please say in your next Journal (1) can a Poor-law medical officer sue for attendance without having the dates of visits, &c., when the attendance cannot be denied; and (2) what is the limited time for recovering such debts; also in a case in a neighbouring district in the absence of the medical officer, I was requested by a clergyman to attend an urgent case, and that the patient's father would pay me. (3) Can I recover my fee from the clergyman or the union?

Yours truly,  
M. J. E.

[1. Certainly. 2. Six years. 3. From the clergyman if you did not receive a ticket for the case, and if the request for your attendance can be clearly proved.—ED.]

**DR. CULLIMORE.**—Case of "Inflammatory Hypertrophy of the Spleen following Ague" received, and will appear in an early number.

**DR. ISAAC ASHE,** Dr. Stokes, Dr. Richardson, Dr. Quinlan, Dr. Connolly Norman—received with thanks; proofs shall be sent in due course.

**DR. D. C. B.**—We have written to Paris, and will communicate to you the result when received.

**W. G. K. D.**—We cannot reopen the subject.

**DR. S.**—See reply to W. G. K. D.

**VENTNOR.**—Yes. The author is a retired army surgeon. We do not know the price of the book; write to the publishers.

**GOING UP.**—The names of unsuccessful candidates are not usually made public for reasons which are obvious.

## NAUSEA OF PREGNANCY.

To the Editor of the *MEDICAL PRESS AND CIRCULAR*.

SIR,—Can any of your numerous readers kindly suggest through the medium of your columns a remedy for the sickness and nausea of pregnancy. The numerous alleged remedies have been prescribed but have failed to remove the constantly distressing nausea (not vomiting) which makes life a burden.

Yours, &c.,  
QUASITOR.

**DR. WISEMAN (Wakefield).**—Thanks, letters evidently crossed.

**MR. J. H. JOHNSTON.**—If you will send the MS. we will give it our earliest consideration.

**D. C. L.**—The paper referred to has been received and its receipt duly noted. Inquiry concerning it shall be made at once.

**AN EAST LONDON RECTOR.**—The mortality from small-pox in London is considerably less this week than for some time past. There is no reason to expect that the disease will continue to spread.

**DR. G. A.**—Review of your recent work is in type and will appear during the present month.

**F.R.C.S.**—Mr. Hutchinson's lectures were commenced on Monday last. They will be fully reported in our columns.

**JUNIOR ATHENÆUM.**—An English translation of Fournier's work on "Syphilis and Marriage" is published. It was reviewed in our last week's issue. Fournier recommends that a subject of syphilis should not marry until after a period of four years' treatment of the disease.

**A SCRIBE.**—We shall refer to the subject next week.

**A QUALIFIED ASSISTANT.**—The subject is fully ripe for discussion. Action in the matter cannot be long delayed.

**DR. THOS. D.**—Letter received with thanks. Suggestion will be taken into consideration. You will receive a private note.

**DR. ALBUT.**—We hope to find space for it in our next.

**DR. C. R. D.** is thanked. The MS. will be utilised in due course.

## VACANCIES.

**Ashton-under-Lyne District Infirmary.**—House Surgeon. Salary commencing at £80, with board. Applications to the Hon. Sec. before June 25.

**Belford Hospital, Fort William, N.B.**—Non-resident Surgeon. Salary, £200, with £40 additional as Health Officer of the Lochaber District. Applications to Mr. N. B. Mackenzie, British Linen Bank, Fort William, by June 20.

**Bolton Infirmary.**—House Surgeon. Salary commencing at £120, with board. Applications to the Hon. Sec. by June 24.

**East London Hospital for Children.**—Resident Clinical Assistant. Board and residence, but no salary attached. Applications to the Secretary at Shadwell, E.

**Liverpool Northern Hospital.**—Assistant House Surgeon. Salary, £70, with board. Applications to the Chairman of Committee by June 24.

**Middlesex Hospital.**—Assistant Dental Surgeon. Honorary. Applications to the Secretary Superintendent before June 25.

**Kilrush Union, Kilkee Dispensary.**—Medical Officer. Salary, £30. Election, June 17.

**St. Peter's Hospital for Stone, London.** Assistant Surgeon on the Staff. Applications to the Secretary before July 1. (See Advt.)

## APPOINTMENTS.

**BARNES, J. G., L.R.C.P.L., M.R.C.S.E.,** Assistant House Surgeon to the Liverpool Dispensaries.

**CARSWELL, J., L.R.C.P.Ed.,** a Physician to Anderson's College Dispensary, Glasgow.

**COOPER, J. W., M.R.C.S.E.,** Medical Officer of the Infirmary and Workhouse, St. George's-in-the-East.

**HAMIL, E. J., M.R.C.S.E.,** Assistant Medical Officer to the Infirmary and Workhouse, St. George's-in-the-East.

**MERSON, A., L.S.A.L.,** Resident Medical Officer to the Workhouse of the Torteth Union.

**NANCE, H. C., L.R.C.P.L., M.R.C.S.E.,** House Surgeon to the White haven and West Cumberland Infirmary.

**PEPPER, A. J., M.B., M.B., F.R.C.S.,** Surgeon to the London Fever Hospital.

**POOLE, W. C., M.B., L.R.C.S.I.,** Assistant Master of the Coombe Lying-in Hospital, Dublin.

**PRICE, W. H., M.R.C.S.E.,** Medical Officer for the Western District of the Corwen Union.

**RAILTON, T. C., M.B., F.R.C.S.E.,** Assistant Medical Officer of the Clinical Hospital, Cheetham Hill, Manchester.

## Births.

**BIRCH.**—June 8, at Sussex House, Downes Road, Lower Clapton, the wife of George Birch, M.R.C.S., of a daughter.

**CHARLES.**—June 7, at 61 West Cromwell Road, South Kensington, the wife of T. C. Charles, M.D., of a son.

## Deaths.

**BARRY.**—June 6, at Ponrane, Dr. Edward Barry, aged 80.

**BIRD.**—June 1, at St. Leonard's Place, York, William Bird, M.D., aged 49.

**BISHOP.**—June 5, at Tonbridge, Kent, Henry Bishop, M.R.C.S.E., aged 49.

**CLOSE.**—June 5, at Sorrento, Italy, Percy Close, M.R.C.S.E., of Dringhouses, York, aged 24.

**SHEPHERD.**—June 4, at Swansea, Jas. Shepherd, M.R.C.S.E., L.S.A.L.

**STEWART.**—June 12, at 34 Welbeck Street, London, W., Louisa Mary, the loved wife of W. B. H. Stewart, F.R.C.S., aged 30.

**WARRY.**—June 7, at 8 College Road, Exeter, Mary Dorothy, widow of Elias Taylor Warry, M.D., aged 78.

**WHITE.**—May 29, at Ferryhill, Aberdeen, Robert White, M.D., aged 61.

## A Course of Lectures

ON

### THE LAWS OF INHERITANCE IN RELATION TO DISEASE.

Delivered at the Royal College of Surgeons of England, June, 1881.

By PROF. JONATHAN HUTCHINSON, F.R.C.S.,

Senior Surgeon to the London Hospital; and President of the Pathological Society of London, &c.

#### LECTURE I.

THE rough facts of heredity are so patent as to preclude all scepticism regarding them. The child is not a re-creation, but is a continuation in respect to the distinguishing features of its progenitors; every portion of the new-born body, each organ, tissue, and cell is derived from its parents; the new structures partake of their substance, and in turn assume similar functions to those discharged by their progenitors in the past. The same forces, in fact, are constantly in action, and like results follow in all cases from their activity; but although these prominent truths have been widely recognised, there cannot be yet said to have arisen definite conceptions concerning the influence exerted by them over the inheritance of qualities and of forms. Complications are set up in the endeavour to deduce important conclusions as to it: 1st. by the possession of a twofold parentage by the organism; and 2nd. by the consequences that follow from the existence of *atavism*; these together serving to invalidate the otherwise necessary law of exact resemblance between a child and its immediate ancestors; and since each child bears relation to two parents, four grandparents, eight great grandparents, and sixteen great great grandparents, it follows that one source of complication may assume almost incalculable proportions to increase the uncertainty experienced when discussing the problems of inheritance.

The influence of heredity over disease is a subject of extreme complexity, and much of the knowledge we have respecting it is, at best, only superficial, although the recent immense progress in zoology has done much to help in the matter, and in reality affords the principal items of our knowledge of it.

Everything that is born with man is capable of being transmitted to his offspring, it often indeed occurs that the date of recurrence of the defect after birth is the same in the descendant as in the ancestor; but it is observed that instances of abnormal development are repeated with more frequency when they are in the direction of excess than when in that of deficiency.

The term disease, used in relation to inheritance, must necessarily be assigned a very wide meaning, and be permitted to include also malformations. Some diseases may be strictly inherited; that is, the disease itself be transmitted, as occurs with syphilis, colour-blindness, &c.; but of others it can only be averred that a tendency to them is inherited, as epilepsy and rheumatism, the exhibition of the disease depending on the presence of certain favouring conditions, in the absence of which they mostly fail to appear.

*Connate* and *congenital* are terms employed to indicate possession at birth, but it is by no means essential that inherited disease should be apparent at this stage of existence. Intra-uterine affections of the foetus are, however, to be included under the head of inherited diseases, although this strictly, and in fact, refers only to features transmitted to the embryo.

By reason of its intimate and direct dependence on the mother the foetus is influenced in a two-fold manner by the maternal parent; whereas the father exerts but a single power over its development. The evidence, however, of an influence on the foetus through the nervous system of the mother is most untrustworthy, and in respect of intra-uterine life, it can only be said that whatever affects the blood of the female parent, reacts also on the child; but the accounts of congenital deformities, associated with mental impressions, received during pregnancy by the parent, are unsupported by any valid observations. The effects that follow on the reception of shocks are of another kind, and admit of other and rational explanations.

The birth of offspring possessing definite resemblances to far removed ancestors is by no means uncommon. The College of Surgeons is in possession of the oldest discovered proofs of this recurrence of characters after long intervals. Certain pictures of animals hanging on its walls, and representing horses born with stripes and markings resembling those of ancestors older than their immediate parents, being of this kind. Peculiarities of temper, too, as well as external markings, are oftentimes transmitted, a fact of which breeders may possibly take future advantage. Some years ago Mr.

Hutchinson made lengthened observations on the influence exerted by a foetus, begot by a syphilitic father, on its mother, and the result tended to show that the contamination suffered by the mother under these circumstances is not sufficient to account for the effects produced on children subsequently begotten, and as explaining them the suggestion offered by L. Agassiz and Darwin, that the seminal fluid may exert an influence over other ova than those actually impregnated by it, is most in accordance with the facts already known. Mr. Darwin, too, has lent new support to this theory by results obtained from experiments made with the pollen of flowers, and it is acceptable as explaining many facts not easy to understand, unless we assume that there is a law in accordance with which the agent of impregnation at one period may suffice to control the products of future intercourse.

The child resulting from the union of sexes is equally produced by each, but there are frequent cases in which it bears resemblance to one more than the other. Such preponderating traits may be inherited *directly* from father to son, or mother to daughter, or *diagonally* from father to daughter, and mother to son. There is also *mediate* inheritance, or *atavism*, under which the characteristic features do not appear in directly successive generations, one or more being skipped, as it were, and a marvellous *latency* of characters being exhibited.

The peculiarities most difficult to be transmitted are those which, like suppression of digits, &c., show a departure, in the way of deficiency, from characters a long time possessed by the race.

A very general impression has for a long time existed in scientific circles that there is a law of alternation of generation, its action being demonstrated through diagonal transmission, as, *e.g.*, is exemplified in those cases where hæmophilia in the mother alternate with colour-blindness in the son, &c. The father is said to transfer his constitution base to his descendants, but the facts adduced admit of other explanations than those offered.

*Prepotency* is a disturbing factor, the influence of which is constantly tending to interference with the effects already considered. It is by no means the same as procreative aptitude. It may be defined as a power of committing characteristics to the offspring, irrespective of their number; but it is difficult of explanation, both in itself and in its mode of action. It concerns itself with little things as with great, and may predispose every tissue and organ of the body indefinitely. The facts in proof of the reality of this power are many, and breeders are well aware of the influence it exerts over the production of stock. The power of prepotency in each sex is slightly preponderates towards the same sex, a principle possible underlying the fact of sex limitation from generation to generation; but, the balance being in other respects equal, the male parent is usually slightly prepotent towards female offspring, and thus in the great number of cases resemblance is borne rather to the father than the mother. Either sex, however, may so preponderate as to efface resemblance to the other, and cattle-breeders avail themselves of this possibility in the selection of animals for their purposes. It is remarkable to what an extent the personal peculiarities of a parent may prevail by reason of its superior prepotency. Thus a boar pig was in the possession of Mr. Hutchinson to which three sows bore 27 pigs, all but three being sows; and there is a record of an Irishman who was married three times, and who begot forty-seven children, forty of them being males.

Prepotency is itself transmissible, and occasionally the same individual exhibits evidences of its possession by both parents. In the way of assisting to determine the effects of inheritance, much valuable information is to be obtained from a consideration of the influence exerted by this power, and even the collateral descent of an individual cannot fail to be of service in helping to determine the result of his ancestors' distinguishing characters. What often appear to be irreconcilable facts may be explained by the help the laws of prepotency afford. The influences of the sexes on inheritance is assumed to be very important, and the share taken by each in the production of the offspring has been attempted to be shown. Thus the female is said to contribute the vascular and nutrient factors, while the male gives form and shape. According to a second theory the child develops in halves, one from each parent; and another suggestion imputes the determination of size to the influence of the male element. This, however, is denied by those who hold an opposite opinion, ascribing this determining power to the

female parent. The wisest conclusion, however, is, that both parents are equally concerned in the production of their offspring, and in the transmission to it of the distinguishing features of its organisation. The horse and the ass will breed easily, and the cross possesses the characters of the one as much as of the other parent; Mr. Hutchinson's own investigations on this subject all tend to show that there is no invariable law in accordance with which children especially resemble one or other parent. A mule is a modified horse, but it is also, too, a modified ass; and in the carts of certain costermongers may be seen any day in London a graceful animal whose bushy tail and drooping mane remove it from the donkey, and bring it into near relation with the horse. The callosities observed on the limbs of the horse, and the true explanation of which has yet to be discovered, have an interest in connection with the question of descent. The horse possesses four of these excrescences; the ass, two. In the mule, however, they are usually four, one in twenty being the proportion in which the number varies, on the average; but the callosities on the hind legs are very frequently small. The ass-like mule, moreover, may present no callosities at all, and consideration of all facts tend to show how little dependence is to be placed on descriptions assigning preponderance of traits invariably transmitted from one or other parent. It has been asserted that there is a constant diagonal transmission of characters, in obedience to a law governing such transmission, but the evidence in proof afforded by mules, or by any other animals, is insufficient and uncertain. Among 300 mules possessed by the London Tramways Company, there were no individuals with marked differences to determine the influence of one parent more than another, except mere size, which may easily be influenced by the mother during the existence of the young in utero.

#### ON THE DIAGNOSIS AND TREATMENT OF APOPLEXY. (a)

By THOMAS STRETCH DOWSE, M.D., F.R.C.P. ED.,  
Physician to the Hospital for Epilepsy and Paralysis,  
Regent's Park.

(Continued from page 507.)

I WOULD venture particularly to impress upon you the importance of never neglecting certain head symptoms, which are premonitory of apoplexy. That these symptoms are due to congestion of the brain I am not prepared to say, although I most firmly believe that they are when they are not associated with an epilepto-genetic idiosyncrasy. What are these symptoms? They are not usually of a severe nature. There is no intense headache, and if the patient goes to his medical man he frequently throws him off his guard by saying that there is not much the matter, and remarking "I only feel a little giddy, and become a little confused in my head at times, and occasionally my head feels heavy, and there is a sense of constriction, as though something were drawn tightly around it, and there is a feeling of stiffness at the back of my neck, and my arms feel heavy, and (a very unusual thing for me) my feet are very cold, and after my meals I feel rather sick, although my appetite is good, and my bowels are acting well. I don't think there is much wrong, Doctor, if you will just give me a little something to act upon my liver." Now, I say that the practitioner of experience will see at once that his patient is suffering from a condition of brain which may at any moment be the seat of such an amount of hæmorrhage as to produce his death in the course of a few hours. Then what course does he adopt to prevent an extravasation of blood on the brain. There are two modes of treatment which, in my experience, should be had recourse to, according to the cause of the symptoms which have just been enumerated, for these symptoms may be produced by arterial congestion with venous deficiency, or they may be produced by venous congestion with arterial deficiency. It not unfrequently happens that the general appearance of the patient will indicate to which of these two states his symptoms are referable. In that state where we find arterial congestion we shall also find increased arterial tension; the pulse will be more or less full and incompressible, it may be hard and whipcord-

like under the finger; the urine scanty, high-coloured, and loaded with lithates; the eye may be bright, and the pupils exceedingly active to light. In a case like this I never hesitate to cup my patient freely at the back of the neck, to administer a free mercurial and saline purge, followed by a mixture of ergot and bromide of potassium, perfect rest and a non-nitrogenous diet being made compulsory. On the other hand, where we have a condition of venous congestion with arterial deficiency, we find that the patient will be more or less drowsy and lethargic. The pupil may be contracted or dilated; it does contract to light, but it does so tardily. The mucous surfaces of the conjunctiva, the lips, the tongue, and the gums will be of a dark venous hue; the skin will be sweating and clammy; the pulse will be soft, small, compressible, and variable; the urine will be secreted plentifully, with a deficiency of ureo; and the heart's action will be exceedingly weak. Now, surely, our treatment in this case will, as a matter of course, vary from that of the condition previously described. I do not consider that local or general bleeding in a case of this kind is at all desirable, and I should not recommend its adoption. The treatment which I usually find most effectual is an alterative mercurial course of blue pill with quinine, to be taken night and morning, and a mixture three or four times during the day consisting of bromide and iodide of potassium, with the tr. of digitalis, and the diet should be highly nutritious and easy of digestion. I hope, in thus placing before you two opposite conditions of the brain, each of which may lead on to apoplexy, both of which, however, differ essentially in their main features, as well as in their treatment, it will not be considered that I have digressed in any way from the main object of my lecture; and I take the opportunity to state here what I have observed before—That, if the majority of nervous diseases are to be cured we must study with the utmost care and precision their initial signs and symptoms, and treat these with promptness and courage with the most potent remedies which we have at our command.

I now pass on to the diagnosis of an apoplectic fit. If a man has an extravasation of blood into the medulla oblongata (which is exceedingly rare unless in association with tumour and softening) he falls down and dies instantly. Hæmorrhage into the pons varolii and fourth ventricle, if extensive, is usually attended with sudden and profound unconsciousness, from which the patient never rallies. It is well that we should at once bear in mind that there are several conditions of the brain which may, in many important particulars, be confounded with apoplexy, and to these I shall allude. But previous to this I should like to draw your attention to the main and essential signs which are indicative of the true apoplectic condition. Profound coma is, of all others, the essential feature, and there is, of course, general insensibility to stimuli of all kinds. The cheeks and lips are swollen and livid, or, on the other hand, they may be exceedingly pale, but the face has for the most part a bloated appearance; the skin is more or less cold and clammy rather than hot and dry. The eyelids are closed, conjunctiva injected, and the eyeballs motionless; the pupil will vary according to the seat of hæmorrhage. The state of the pupil is certainly of considerable importance as a diagnostic medium, as, for instance, if there be hæmorrhage into the ventricle of the brain, the pupils will be widely dilated, and no contraction can be induced, either by direct or indirect agency, whereas, if the lesion exists in the pons varolii, the pupils will be found to be minutely contracted. Now, in these forms of hæmorrhage I have stated that the pupils of the eyes are not influenced by peripheral stimuli, like they are, for instance, in uræmic coma and alcoholic poisoning. Now, if these forms of coma which I have just referred to are not of most severe type, and of the last degree, peripheral stimulation by the Faradaic brush to the temporal region will produce reflex action of the ciliary muscles. There may be also conjugate deviation of the eyes, to which I shall shortly again refer when speaking of localised

apoplexies. The whole of the arterial system appears to have undergone a change; the circulation has become disturbed, and the carotids and temporal arteries will be seen to throb violently. The pulse is usually full and strong, and gives evidence in the majority of cases to the existence of increased tension. The respiration is regular, heaving, or deep, and is for the most part associated with stertor and puffing expirations. Now these signs and symptoms which I have just narrated are significant of a state of profound coma; but it is by no means necessary that these symptoms should be so markedly profound, and just according to the suddenness, extent, and seat of the lesion, so we shall find the degrees of coma to be more or less marked. The deepest state of coma is produced by hæmorrhage into the pons varolii and into the lateral ventricles. The variations in the body temperature during the apoplectic fit are striking and important. I remember, some years ago, when I had an unlimited field for observation at my disposal, making some experiments in rectal thermometry in these cases, which exactly accorded with the researches of MM. Charcot and Bourneville, at the Salpêtrière, in Paris. The temperatures, pulse and respirations, condition of pupil, and reflex excitability were carefully noted during the three stages—namely, the stage of depression, the stationary stage, and the stage of reaction; or, as Dr. Bastain puts it—the period of initial lowering, the stationary period, and the ascending period of body heat. The temperature during the stage of depression has been known to fall to 95° F., and during the stage of reaction, or ascending period, it has risen so high as 106° or 108°, whilst the temperature during the stationary period will vary if the patient is to recover from 100° or 103° or even 105° F. We shall find that these variations in temperature, and especially when they are considered in relation to the pulse and respiration are important guides in our prognosis, if the hæmorrhage is extensive and the depression extreme the patient dies in a state of collapse in the course of an hour or two; yet, if the patient survives the period of initial lowering he has yet to combat the stage of a too vigorous reaction; and should the temperature progressively and somewhat rapidly rise to 105° or more, with rapid pulse and respirations, and pronounced coma, there is no chance of the patient's recovery. Then we have the stationary or intermediate period, and we can almost invariably give a hopeful prognosis if, during this period, say, of twenty-four or forty-eight hours, there is merely a temporary rise of temperature, which is soon followed by a fall within the range of the normal temperature of the body. In the coma of uræmia M. Bourneville says the temperature of the body begins to fall at the commencement, and continues to sink as long as the condition persists, so that it may fall as low as 90° F. in fatal cases. On the other hand, in the coma due to cerebral hæmorrhage or softening, the lowering of the temperature is slighter in amount, and in cases not fatal within this period rarely lasts longer than twelve to twenty-four hours. If the hæmorrhage should occupy one hemisphere of the brain, giving rise to paralysis of the opposite side, we shall find that the temperature of the paralysed side will be from one to two degrees higher than upon the non-paralysed side.

I have referred to conjugated deviation of the eyes. This is a very interesting and pretty constant accompaniment of the apoplectic state. Both the head and the eyes will be, so to speak, driven over towards the non-paralysed side, and in the direction of the brain lesion. M. Provost, who has written an interesting memoir on this subject, states that this condition of conjugated deviation of the eyes and rotation of the head rarely follows lesions of the pons varolii. Both eyes are turned as they would be if the individual were looking upward over one or other shoulder. The eyes are usually motionless, but sometimes they oscillate in the same manner that they are found to do in that peculiar condition of nystagmus which we know to be a constant accompaniment of insular sclerosis of the brain.

Before leaving the question of general diagnosis of the

apoplectic state I should like to make one or two observations concerning the differential diagnosis of states of insensibility which simulate a true apoplectic state. Of course there are many causes which produce like effects. In reference to unconsciousness, which we find as the result of hæmorrhage, emboli, and thrombosis of the brain, for instance, we must not forget, when we find a patient insensible, with stertorous breathing, that this may be due to compression of the brain through an injury. An epileptic falls suddenly in a fit; the effects of the fit pass away, but he may remain apoplectic from compression of the brain caused by fracture of the skull which was due to the fall. It may, in some cases without any history to guide us, be a difficult task to diagnose between opium poisoning and hæmorrhage into the pons varolii. In the former the onset is gradual, whilst in the latter the onset is sudden; we find, however, in each case the minutely-contracted pupils, profound stupor, closed eyelids, cold, clammy, perspiring skin, and complete absence of reflex movements. Uræmic coma will not, I think, as a rule, be confounded with apoplexy; it is usually associated with a pale pasty complexion, puffy eyelids, and œdema of the extremities, and is generally associated with twitching of the limbs, and more or less rigidity, which are not localised; and furthermore, as M. Bourneville has pointed out, the temperature of the body begins to fall with the onset of uræmic coma, and continually to sink as long as this condition persists, so that it may fall as low as 90° F. in fatal cases. Epileptic coma, which not unfrequently follows the convulsive stage of an epileptic fit, is of short duration; otherwise it is almost impossible to distinguish it from apoplexy. It occasionally happens that an apoplectiform seizure with convulsions may terminate in a profound apoplectic fit, which sometimes ends in death. I may remind you that in the majority of these cases the body temperature will aid us greatly in making a diagnosis if we remember that cerebral hæmorrhage is invariably attended in the onset by a marked lowering of temperature, which gradually rises, even to 108° or 110° F.; whilst in the apoplectiform seizures which are associated with disseminated sclerosis and general paralysis of the insane the temperature of the patient invariably begins to rise from the first, so that in a few hours it may reach 104° or 105° F., and in fatal cases the temperature was still higher.

From this and previous remarks which I have made concerning the body temperature in these conditions, I think it will be at once recognised how important it must be in all these cases to satisfy ourselves upon this point before attempting to give a prognosis. It is quite impossible for me, in the course of a single lecture, to discuss and differentiate the symptoms and signs of an apoplectic state due to embolism and thrombosis apart from hæmorrhage, and I assure you that it is not always an easy matter so to do. This much I may say—that thrombosis and embolism are both much more common than is usually supposed, and especially thrombosis. Bastian, in referring to the diagnosis, says—"All that we can say is that a very abrupt onset, in a young person more especially, and in association with the condition named, tells strongly in favour of embolism, and that long or well-marked prodromata, terminating with an attack of hemiplegia in an elderly person points almost as strongly in favour of thrombosis.

Of the different regions of the brain where hæmorrhage may arise we can have no very definite evidence during the apoplectic fit. Should there be central hæmorrhage into the pons varolii the coma is very profound; the pupils are minutely contracted; the buccinators are flapped out with each expiration, and there is an entire absence of sensibility.

Where we have effusion of blood into the ventricles, following hæmorrhage in the neighbourhood of the corpus striatum and optic thalamus the coma is profound, the paralysis general and complete, and the pupils are widely dilated; tonic and clonic spasms, with rigidity, may exist,

and frequently conjugated deviation of the eyes. The anterior lobes are rarely the seats of hæmorrhage; I have, however, met with several such cases. Now hæmorrhage into the frontal lobe of the cerebral hemisphere is not usually sudden, and is not attended with immediate loss of consciousness; yet it usually terminates fatally if at all extensive. Like other cerebral apoplexies, it is preceded by more or less loss of smell and mental confusion and dulness. Hæmorrhages into the cerebellum are rare, and when they occur are most frequently associated with tumour and softening, so one may say that cerebellar hæmorrhage takes place more often in the young than in the middle-aged or the old. Death is invariable and sudden.

In the treatment of apoplexy it is highly important that we should take all the circumstances of the case into consideration. To say that it would be wise or unwise to bleed would depend entirely upon the age and constitution of the patient, the power of the heart, and the force of the circulation. To say that apoplexy is not associated with a more or less congested state of the brain in a majority of cases is to my mind untrue, although I quite believe that many of the cases of apoplectiform congestions are, in fact, no congestions at all, and it matters little to the patients whether they are bled or let alone, for they invariably recover. There is no one who has ever seen a person suffering from the initial stage of apoplexy who has not been struck with the disturbed state of the circulation. If the patient be full-blooded and æthenic with a bounding pulse, which does not yield readily to digital pressure, with the temporal arteries beating violently, with the cheeks red and livid, whether coma were profound or not, I should bleed that patient to the extent of twenty ounces, or I would cup him at the back of the neck to the extent of twelve ounces; and I should think that I had failed in my duty to my patient if I did not do so. I am not in agreement with those who do not believe that blood-letting prevents or diminishes the cerebral hæmorrhage; and I maintain, on the contrary, that where the conditions are such as I have just indicated blood-letting does relieve the force of the heart and circulation, and in this way lessens the arterial tide which has set in towards the cerebral vessels. There is, in cerebral hæmorrhage, vaso-motor nerve paralysis and inefficiency, especially in reference to the vessels of the brain there is increased arterial tension and cardiac force, due to inhibition of the pneumogastric nerve, and by thus relieving the general circulation of blood the vaso-constrictor paralysis which pre-existed is thus removed, and the vessels in a measure regain their normal contractile power and calibre. It is my opinion, gentlemen, that it is quite possible to check a cerebral hæmorrhage by bleeding. I am quite willing to admit that it is useless to bleed or to do anything else if the substance of the pons varolii is destroyed by hæmorrhage, or if the ventricles be distended with blood, but we are not sure, gentlemen, of either of these conditions until the brain is upon the post-mortem table. During the past seven years I am quite certain, as far as I can well be, that I have saved life in cases of cerebral hæmorrhage by the letting out of blood.

Now, let me draw your attention to the other side of the picture, where I believe blood-letting would aid in destroying rather than saving life, and the condition I would here depict, where blood-letting is contra-indicated is as follows:—A general feebleness and æthenic habit of body, a weak heart, and a soft, weak, and compressible pulse, a cold clammy skin, coldness of the extremities, tips of the nose and ears, and a body temperature below the normal and advanced age. I can see no reason why patients should not sometimes be bled with advantage because they are old—and by the term old I mean between the ages of 50 and 65. This is a theme upon which one may dwell for some time, but I must pass on to other modes of treatment. A very good observer, Dr. Austin Flint in his excellent work on "The Practice of Medicine," says that an emetic is sometimes indicated when the

stomach is overloaded, and he cites one case where its beneficial influence was well marked. I can only see the object of this reasoning from one point of view, namely, that a quantity of food in the stomach during an attack of cerebral hæmorrhage remains undigested and contributes to collapse, which means vaso-motor paralysis and increased hæmorrhage. I scarcely know of any condition, either of heart or pulse, when a stimulant cathartic can be otherwise than beneficial, and there is nothing better than two drops of croton oil. It is an old-fashioned but efficient remedy. An injection by the rectum of one pint of gruel, two-thirds of common salt, and 1-23rd of turpentine may be administered with considerable advantage, and without, as far as I can see, any chance of doing harm. There is one special advantage which this injection treatment can lay claim to, and it is this—that it will often clear up a case where the diagnosis is doubtful, and where the coma is apoplecticiform only or due to drink. We have, again, our asthenic apoplexy to consider where we would not bleed, and where, in fact, I should say wait awhile and do very little, but keep up and maintain the body-heat by wrapping the extremities in flannel, and apply bottles of hot water to the armpits and to the feet. If the pulse is very weak and flickering and the breathing slow, injections of brandy must be given, but very cautiously. Injections of ergotine have great power in contracting the vessels, and so arresting hæmorrhage. Dr. Bastian prefers the bromide of camphor to diminish the flow of blood through the brain. Under any circumstances the patient should be placed in a cool, airy, well-ventilated apartment; the head should be raised from the small of the back and not chucked up at a right angle with the trunk, as though every effort were being made to close the opening of the glottis; and if, during the stage of reaction the head becomes very hot cold evaporating lotions and the ice-bag must be kept continuously applied. When the patient merges from the apoplectic state, and when we are led to hope and believe that hæmorrhage has ceased, it is unwise to be too officious; it would be found that the patient at this time will swallow fluids as automatically as a new-born child, and nothing more need be given than peptonised fluid beef, or peptonised milk. If there be great exhaustion it may be necessary to have recourse to stimulants, and I do not hesitate to say that they may be administered with great advantage in many cases, but unless they are very carefully given I am convinced they may do more harm than good. Let us consider for one moment what is the pathological state of the brain with a foreign body (a clot of blood) in its midst. A brain which is the seat of apoplexy suffers from solution of continuity at the part itself, and also from displacement corresponding to the size of the cavity, so that of necessity, if the patient is to recover, the clot must be followed by numerous changes, and so also must the brain substance in contiguity with the clot. Under any circumstances the brain substance which is contiguous to the clot must undergo slight inflammatory and sclerosal change, forming a cyst wall; or, on the other hand, it produces general softening of all the adjacent parts, and I need scarcely say that the treatment of these cases must be directed to prevent this process of softening from extending, so that our great object must be to equalise blood-pressure, to maintain the nutrition of the parts, to improve in every way the condition of the blood, and to secure mental and physical rest.

#### A TYPICAL CASE OF HYDROPHOBIA.

By T. M. DOLAN, F.R.C.S. Ed., Halifax, Yorkshire.

The principal features of interest in the following case I shall first briefly summarise:—

1. It illustrates the great assistance which may be derived from the police, in connection with rabies and hydrophobia.
2. It proves the great danger from bites on the face.
3. It confirms previous evidence as to the short period of incubation in children.

4. It seems to strengthen my opinion on the necessity of having a consultant of the character pointed out in my work on "Hydrophobia."

5. The whole chain of evidence as to the boy being bitten by a rabid dog is complete, and it afforded a comparison being made of the pathological changes found in the dog, with those in the boy.

6. The excessive sensitiveness of the organs, of touch, sight, sound, are typical.

7. As one among many deaths that have occurred in Yorkshire during 1879, it convinces me that a more stringent Dog Act is required.

On November 10th, 1879, I received information from Lieut.-Colonel Ormsby, Halifax, that a rabid dog, a setter, had been destroyed at Keighley after biting several dogs, and inflicting injuries on two children and a man. I immediately wrote to Captain Stuart Russell, chief constable at Wakefield, and by his orders the animal was at once sent to my house, and at once forwarded by me to the Brown Institution, London, in order that the Committee, appointed by the British Medical Association, might have an opportunity of carefully examining the dog, so as to verify the diagnosis of rabies.

We are told that there is an anatomical lesion characteristic of rabies, consisting of the presence of an accumulation of white globules within the perivascular lymphatic sheath on the floor of the fourth ventricle, and of apoplectic centres made up of these globules. I also thought that a series of experiments might be instituted with the saliva and blood on rabbits or other animals, so as to test in various ways the virulency, or not, of the secretions and tissues. All animals bitten by the rabid dog, as far as could be known, were immediately destroyed, and the children and man were attended to by a medical man, their wounds being cauterised with nitrate of silver.

The superintendent informed me that on the first appearance of symptoms of illness, in any of the injured persons he would, with the consent of the medical attendant, telegraph for me.

On Monday, December 15th, I received the following telegram:—"The boy bitten some weeks ago at Keighley very restless, has not swallowed anything for two days. Dr. Dobie attending thinks it a case for immediate attention." I went over same day and met Dr. Dobie, who very kindly availed himself of my assistance. Through his courtesy I have been able to furnish some of my notes.

Dr. Dobie informed me that on 10th Nov., 1879, the boy, Charles Edward Lily, æt. 9½, was taken to his surgery about two hours after the infliction of the bite. There were three wounds on the face, one above left angle of the mouth crescentic, one inch, one at the lower angle, seven-eighths, and one at the ala of the nose, three-eighths of an inch.

Dr. Jack cauterised the wounds freely with nitrate of silver, and they healed in the ordinary way.

Nothing was done or said to turn the boy's thoughts to hydrophobia, or to alarm him in any way; but without letting him know he was under observation.

The boy went well up to Saturday, Dec. 13th, thirty-three days after the infliction of the bite, when he complained of general malaise, restlessness, feverishness, and inability to swallow. He was attended to by Dr. Dobie's assistant.

Condition remained the same on Sunday.

On Monday I saw him with Dr. Dobie; he was dressed and sitting on his mother's knee, as he was restless and would not remain in bed. At this time the excessive sensibility to touch and sound was well marked, and the slightest noise or current of air set up reflex action, and produced an involuntary shudder. He answered questions readily, said he felt very cold, and held his hand to injured side of mouth as if to keep it warm. Difficulty and abhorrence of drinking were most marked; he had all the will and desire to drink, but as soon as a cup reached his mouth it produced a sudden start, followed by a general convulsive wave through the body. There was not an excessive flow of saliva, though he very frequently spat on the floor. As I was anxious to collect some of the saliva, we tried to induce him to spit into a cup or saucer; but the first effort induced a similar spasm to that brought on by drinking, and he would not repeat the effort. This was probably attributable to the association, with his former experiences of drinking from a cup. His temperature was slightly raised, heart's action jerky, irregular, and accelerated;

pulse thin, irregular, and frequent; eyes bright, glistening, and expectant. He was irritable and could not bear contradiction.

The secretions had acted fairly. The expression of his face reminded me of the risus sardonicus, though it was not so marked, but there was a peculiar elevation of the angles of the mouth which produced an effect like that seen in the sardonic smile.

Dr. Dobie and I agreed:

1. That it would be desirable to get the boy to a hospital, for in the house in which he was there was no adequate means of carrying out treatment. Dr. Dobie kindly offered to undertake all expenses, and to get the child into the Keighley Cottage Hospital.

2. That a Turkish or vapour bath should be administered. Unfortunately, maternal consent could not be obtained for either of these essentials for the successful treatment of a case of this nature.

3. Under such conditions we decided that the child should have injections of bromide of potassium, beef tea, and other nutriment; so, virtually, our hands were tied by the fond but foolish love too often seen amongst mothers, who prefer their own gratification to their offspring's welfare.

Dr. Dobie and his assistant undertook to administer the injections themselves. I telegraphed to the Hydrophobia Committee, and received a reply that one of the members would come down, and it was arranged that Dr. Brunton should be the one.

Tuesday, Dec. 16th.—Condition almost same; continued treatment.

On Wednesday morning I saw the child again. He had passed a restless night, but one symptom had improved, he had expressed a fancy to drink, through the stem of a long tobacco pipe, a cup of milk, some beef-tea; he had also taken nearly half a pound of grapes and some other fruit. Otherwise he was not much better; he spat about the room incessantly, and Dr. Dobie had collected some of the saliva in a saucer in order to test my suggestion, that some rabbits should be inoculated with it. I intended to fill some tubes with it for future experiments. The sensitiveness of the body was increased, the slightest current of air sent a thrill through him; temperature slightly raised, pulse thin, thready, and frequent.

Dr. Brunton came down from London on Wednesday night, and saw him on Thursday morning, when his condition had very much altered for the worse. He had passed a restless, sleepless night; his pulse was so frequent it was uncountable, and could only be approximately estimated by listening to the heart's sounds. The peculiar facial expression previously noticed was unaltered, and he still held his hand to the side of his face. He presented the appearance of an animal who had been hunted, and was in that exhaustive, suspicious, irritable condition, with palpitating heart and anxious look so often seen when sleep and food have been denied. He had eaten some grapes and drank some milk through a pipe stem. The saliva had increased in quantity, and the spitting was now more frequent; and though he spat freely all over the floor, any attempt to spit into a circumscribed space, brought on not only an inhibitory spasm, but a general convulsive tremor. Hyperaesthesia had increased. Dr. Brunton agreed that the case was one of true hydrophobia, and thus an official diagnosis I may say was established, a most important desideratum in all cases. I have known grave mistakes made in this respect; in my work on "Hydrophobia" I have pointed out diseases with which this disease may be confounded, and produced evidence to show that this had been a not uncommon mistake. Through mistaken diagnosis the death-rate from true hydrophobia is falsified. Dr. Brunton's suggestions were to continue the bromide of potassium, and to induce sleep to add some chloral, but from the surrounding of the patient he saw there could be no other result but death. The child died on Thursday, Dec. 19th, at 6:30 p.m.

*Post-mortem Notes.*—Charles Ed. Lilley, *æt.* 9½, died Thursday, Dec. 18, 6.30. *Post-mortem.*—Friday, Dec. 19, 7.30. Present, Drs. Dobie, Rabagliati, Chaffers, Dolan, and Jack. *Post-mortem* made by Drs. Dobie and Rabagliati.

1. *General Observations.*—Body fairly nourished. Rigor mortis most marked. Hypostatic congestion; lividity about ears, less on right. Abdomen very much distended. Great escape of gas, *per anum*, when body was turned. Smell most offensive. Prepuce livid. Escape of fluid, from nostrils and

mouth, collected and forwarded to Dr. Brunton. Three cicatrices left side of face: one above angle of mouth, crescentic, one inch; one lower angle, crescentic, 7-8ths of an inch; one near ala of nose, 3-8ths of an inch. No special appearance in wounds.

2. *Cranium.*—On removing scalp, bright patches over right parietal eminence, size half-a-crown. Calvarium taken away. Brain removed for examination microscopically. Unusual attachment of dura mater at occipital region. Surface in a general state of congestion. Forwarded to Dr. Brunton.

3. *Thorax.*—Lungs normal; no adhesions of pleurae. *Heart.*—Right ventricle containing blood, left ventricle in contraction; clots at mitral valves. As regards weight, size, &c., normal.

4. *Abdomen.*—Stomach empty; some post-mortem solution; transverse colon distended greenish; the whole of large bowels same state, not so marked in lower portion. *Liver.*—Greenish black on surface; section forwarded. *Kidneys.*—Hyperæmic; on section, congested specimen taken. *Appearance* normal; specimen forwarded to Dr. Brunton. *Bladder.*—Empty; retracted and contracted extremely. Nothing else worthy of note.

5. *Spinal Cord.*—Exposed; cord examined *in situ*; six, consistence, seemingly normal, though surface appeared congested; fluid normal; cord removed, and placed in a solution of methylated spirits, and sent to Dr. Brunton.

6. Portion of sub-maxillary gland removed, and sent to Dr. Brunton.

7. Small syringe filled with blood, and sent to Dr. Brunton.

8. Small capillary tubes, charged with saliva, taken from boy whilst alive, sent to Dr. Brunton.

9. Specimens forwarded by 12.30 a.m. train from Keighley, by Dr. Dobie.

*Post-mortem* concluded at 10 p.m.

*General Observations.*—The specimens were sent to the Committee of the British Medical Association, in order to assist them in their laudable work, by placing material at their disposal.

Though this Committee was made up of physicians and surgeons who were well known to be histologists, physiologists, physicists, pathologists, and therapists, I regret to say that their services have not been called into requisition, as often as could be desired. This is very much to be regretted both in the interest of science and of the public.

No more liberal offer could be made than that men of high standing in the profession should leave London practices, to give the benefit of their advice to hydrophobic sufferers in any part of England, and it redounds to the credit of the metropolitan branch of the profession that such an offer should have been made, even though it was not responded to.

I sent some tubes filled with saliva and blood. My object was to try to solve the question as to whether hydrophobia could be communicated by human saliva to the lower animals, as I believed this would afford a *crucial test* (a) in doubtful cases of hydrophobia.

Rabbits are peculiarly susceptible of the rabid poison, and the saliva of human beings injected into them has produced rabies.

Some French surgeons have adopted this test, amongst whom I may mention M. Maurice Raynaud.

The Brown Institution offered a fitting field for solving this question, as it possessed every instrument, appliance, and material for carrying out experiments of this nature.

In reference to bites on the face, statistics prove that they are the most dangerous, and hence in our treatment of them we require more severe measures than in wounds in other parts of the body. I believe such wounds should be incised, and blood freely let out, and some form of cupping glass be applied, so as to encourage the flow of blood, and in applying caustic, nitric acid should be used. Nitrate of silver simply forms a crust, and incarcerates the poison.

Under the unfavourable circumstances under which the child was placed, any attempts at treatment were nullified, so that all such cases should be removed to a hospital, where such treatment as a Turkish or vapour-bath can be satisfactorily given, and where the patient will be under the constant care of doctor and nurse. Bromide of potassium, in 40 to 60 grain doses, appears to me one of the most appropriate sedatives that can be given, whilst we have in quinine another medicine which may be usefully turned to account, the latter being selected on physiological grounds.

(a) See correspondence, *Lancet*, under heading "A Crucial Test for Hydrophobia," 1879.

Yorkshire and Lancashire have suffered extensively from hydrophobia during the past ten years; its densely populated towns, with a dog-loving population, the want of care bestowed on the animals, and the want of restriction, partly account for this. Contagion explains the rest of the problem, and we can trace the chain as far back as 1861. In the essay submitted to the College of Physicians, under the title of "Miltarum Aurorum Opus," I have fully entered into the subject, and produced evidence which would convince the most sceptical that a new Dog Act is imperatively required.

## Clinical Records.

### LONDON HOSPITAL.

#### *Case of Fractured Base—Compression—Trepining—Death.*

Under the care of Mr. TREVES.

Reported by W. COATES, Dresser to the case.

THOMAS D., set 46, was admitted into the Hospital on January 17th, under the following circumstances:—

It appears that about three hours previous to admission he was helping to remove some casks from a ship in the West India Docks, when he slipped and fell backwards into the hold, a distance of sixteen feet, his head striking violently against an iron projection. His friends state that he was insensible only a few moments, during which time his body tossed about from side to side; but he thoroughly regained consciousness, was able to converse sensibly with those around him, and sufficiently recovered to be able to walk to the residence of a medical man—a quarter of a mile away—where a severe scalp-wound which he had sustained was stitched up. He went home to bed, but as he complained of such severe pain in the head and was evidently gradually becoming unconscious, he was removed here.

When first seen at 11.30 p.m., patient lay on his back, apparently in an almost comatose state. He paid no attention to anything that was going on; made no effort to speak; nor did he appear to hear anything that was said to him; in fact, he was insensible. But his insensibility was not profound, because reflex irritability could be induced. When disturbed he moved about, and his movements were free and forcible, and complex in character; but it was noticed that they were all confined to the right side, the left extremities remaining perfectly motionless. The movements excited were evidently not altogether without purpose, for if his beard were pulled he would at once with his right hand resist the operation; and on an attempt being made to examine the scalp-wound, he would grasp the hand and endeavour to prevent manipulation. His pulse was beating strongly but slowly, only 48 in the minute; it was full, regular, and compressible. His respirations were slow (18), somewhat irregular, and approaching the "stertorous" in character. At each inspiration the cheeks were "drawn in," and they were "blown out" again at every corresponding expiration. His pupils were markedly unequal. The right one corresponded in size to the gauge of a No. 9 catheter; it reacted slightly to light, though very sluggishly. The left one was very small and contracted, about equal to a No. 1 catheter. It was almost quite stationary, light having little or no influence upon it. A considerable quantity of bright scarlet blood was oozing from the right ear. On examining the head, a large lacerated scalp-wound was found, which commenced over the right parietal eminence, and passed directly backwards for a distance of about three and a-half inches. The scalp had been stripped from the periosteum all round, but especially behind, where the finger passed into a pocket two or three inches in depth. The bone was denuded of periosteum for the space of about an inch; but, although carefully examined, no fracture could be detected. Patient was removed to bed; his head was shaved, and an ice bag was applied.

1.45 a.m.—As the symptoms were becoming gradually more pronounced, Mr. Treves decided to trephine for meningeal extravasation. The operation was performed in the usual way. A crucial incision was made, the centre of which corresponded to a point about one and a-half inches behind the external angular process of the frontal bone, and half inch above the zygoma. The temporal fascia and muscle

were next divided, and the bone cleaned for the application of the trephine. After all bleeding points had been secured a stout trephine with strong centre pin was applied, and a circular piece of bone containing the groove for the middle meningeal artery was removed without causing any injury to the dura mater. There was not, however, any trace of clot, nor at first was there any bleeding; but after a time a little blood appeared to ooze up from the posterior part of the opening which obviously was seen to be pulsating, but the pulsations are determined to be synchronous with the movement of the brain. Very careful explorations were made in the vicinity of the opening, but as no appearance of clot could be found the edges of the wound were brought loosely together. Cold water dressing was applied, and patient was removed to bed. The paralysis seems in no way relieved by the operation; but the respirations are more regular and less stertorous, although faster (31). Pulse 76; temperature 98.4 deg. Catherisation is performed; two drops of croton oil are administered, and an ice bag is to remain applied to the head.

January 18th, 11 a.m.—Patient is no worse. He has remained in the same condition all night, evidently quite insensible and moaning loudly. His respirations are deeper and less laboured (35); pulse 64; temperature 99 deg. The condition of his pupils and the paralysis remain unaltered. He has passed his urine and feces into the bed. He has taken small quantities of milk and beef-tea.

8 p.m.—Respirations somewhat laboured (28); pulse 88, full and quick; temperature 100.6 deg. There is no improvement. His extremities are warm. Face bathed in perspiration. No movements can now be excited by irritation, although he at times tosses his head from side to side.

19th.—10.30 a.m.—Patient has been moaning all night, and seems much worse this morning. His temperature is 104 deg. His respirations are laboured and irregular (30); and his radial pulse is extremely weak, small, and very easily compressible. He has passed both urine and feces into the bed repeatedly. His feet, nose, and ears are quite cold, and his forehead is wet with perspiration. He is evidently rapidly sinking. A nutrient enema is to be administered.

11.30.—Pulse almost imperceptible.

12.45.—Died quietly.

At the autopsy, which was made on the following day, a large clot, weighing three ounces, was discovered about two inches posterior to the spot where the trephined bone had been removed, and which obviously had been the cause of the compression. There was no laceration of the brain. A fracture traversed the right half of the base of the skull, extending from the petrous portion of the temporal bone, close to the margin of the foramen magnum.

Mr. Treves remarked that the trephine was applied in the present instance because the immediate symptoms were distinctly due to a compression from hæmorrhage. The fracture of the base was, of course, a serious complication, but in cases like the present it should not forbid the performance of the operation. The instances of perfect recovery after fracture of the base of the skull are now very numerous.

The present case illustrates the great difficulty of deciding whether the trephine should be applied over the meningeal trunk or over the spot primarily injured. In this case Mr. Treves presumed that a linear fracture, commencing below the scalp wound, might have extended to the base, involving the middle meningeal artery route. On the other hand, the wound occurred over a portion of the skull where the meningeal arteries are few and not of great size. The post-mortem showed, however, that the extravasation was immediately beneath the scalp-wound.

THE annual rates of mortality last week in the principal large towns of the United Kingdom per 1,000 of the population, were—Brighton 14, Portsmouth 14, Wolverhampton 15, Plymouth 15, Newcastle-on-Tyne 15, Nottingham 16, Bristol 17, Hull 17, Bradford 17, Norwich 17, Sunderland 17, London 18, Leeds 18, Birmingham 18, Glasgow 18, Leicester 19, Oldham 20, Edinburgh 20, Salford 21, Manchester 21, Liverpool 22, and Sheffield 23.

### ON PARACENTESIS THORACIS BY ASPIRATION IN ACUTE PLEURISY.

By Dr. GEORGES DIEULAFOY,

Professeur Agrégé à la Faculté de Médecine de Paris; Médecin des Hôpitaux; Lauréat de l'Institut (prix Montyon).

Translated by C. A. OWENS, M.D., L.R.C.P. Ed.,  
L.R.C.S.I., &c.

#### CHAPTER I.

##### *On the Indications for Paracentesis Thoracis in Acute Pleurisy.*

In 1843 and 1844 my distinguished and respected master, —Professor Trousseau, made his first communications to the Academy of Medicine on the "Expediency of Performing Paracentesis Thoracis in Acute Pleurisy," and in spite of the active opposition offered to him for several years, Trousseau, persevering in his convictions, quitted the struggle victoriously, and endowed medicine definitely with paracentesis thoracis, as he had already enriched it with tracheotomy.

When I say he added definitely the operation of paracentesis thoracis to medicine, I do not pretend to say he was the inventor of it, for he said himself, with his extreme modesty, that he claimed nothing; but a perusal of the report of Bicheteau, "a true *chef d'œuvre* of learning and criticism" is sufficient to show that puncture of the chest, so often adopted and abandoned since the time of Hippocrates had only till then been directed to the treatment of purulent effusions, so that paracentesis thoracis abandoned, discredited, and severely blamed by the majority, might still have remained buried in oblivion if Trousseau had not given it his powerful authority, and thus by his success brought it into notoriety. Therefore, if I, following in the footsteps of my master, decide to re-open a subject which he treated so wonderfully, it is not with the intention of modifying the precepts left by him, but rather of replying to objections raised against the operation as performed with the aspirator, and which reflect on the whole question of paracentesis, and furthermore, to offer full explanation as regards those points which I could only deal with when I have accumulated sufficient material for the purpose. With this end in view I made notes of 70 cases of acute pleurisy, and the details of 150 operations of paracentesis thoracis by aspiration; these operations having been performed either by me, or under my orders by the students in the different wards under my charge.

Up to 1869 the operation was performed with Reybard's apparatus, and according to Trousseau's rules; a trocar provided with a valve was made use of, but whether a large or a small trocar was used, the operation was not varied, paracentesis was then actually only an exceptional mode of treatment of acute pleurisy, being generally reserved for those cases in which the effusion was considerable.

But when, in 1869, I introduced the method of aspiration in the treatment of pleural effusion, which method I had just proposed for the removal of all morbid fluids, the mode of operation became so simple, and the aspirator-needle so innocent, that hundreds of operations were performed, I had nearly said thousands, at home and abroad; and, to meet this movement run wild, 83 aspirators of different forms and sizes were invented. What became then of Trousseau's sage precepts and warnings? The chest was tapped at any period of the pleurisy, it was done during the fever as well as after it, in trifling as well as considerable effusions, and too frequently 5 pints or more of fluid were removed at one time, (not remembering that such a sudden withdrawal of a quantity of fluid with the aspirator might of itself involve dangerous consequences. With so many operations, accidents occurred which were identical in every way with those of which the old operation had been accused; a patient would be seized during, or after, the operation with violent pulmonary congestion, acute œdema of the lung with albuminous expectoration, even death resulting; in another, the effusion became purulent, and aspiration was more than once accused of these misdeeds, in the same way as Reybard's trocar had been before.

I acknowledge with regret that the abuse of the operation of paracentesis springs from the use of the aspirator; but in considering this question of abuse it must be borne in mind that the operator was sometimes inexperienced, or at any rate only possessed imperfect knowledge of the operation; for merely using a needle and aspirator is not sufficient, it is essential to know how to regulate the vacuum, and only to apply it when guided by certain rules. My intention therefore is, to give aspiration a more modest place, but at the same time to protect it from censure which it does not deserve; to do this I propose to analyse in detail the different accidents which have been observed, to ascertain their cause and mechanism, and to estimate their worth, hoping to prove that if sufficiently indicated and properly carried out, puncture of the chest by the aspirator is the simplest and most innocent of all operations.

In this important matter of paracentesis, the first point to be considered is:—What are the indications for the operation!

May we operate during the fever or must we wait till deference is established? Should we reserve the operation for those cases in which the effusion is considerable, and apply it as well to cases of medium intensity? and finally, how must we act as regards dealing with the complications which accompany pleurisy? The whole of these oft-mooted points resolve themselves, in my mind, into two propositions which I thus sum up. Given a case of acute pleurisy, two conditions have to be met. *In the first, the operation of paracentesis is imperative, in the other it is a matter of question.* When is it imperative, and when doubtful? This is the field of discussion open to us.

The urgent necessity for the operation can only be based on one element, viz:—by estimating the quantity of fluid effused. The patient may be feverish or not, the disease may be beginning or ending, the breathing may be oppressed or free, it matters little, these are only secondary considerations, we must before everything consider the quantity of fluid effused. To trust to dyspnoea as a guide would be a great mistake, because it is such a deceptive symptom, and I could cite numerous examples, where a person affected with pleurisy walked about with 4 or 5 pints of fluid in his pleura. Trousseau relates the case of a nurse who walked, carrying her child with her, from Point St. Eustache to the Hospital Necker, having thus walked about 2½ miles without feeling very fatigued; and the effusion in her chest was so considerable, that paracentesis, which was at once performed, gave issue to four pints of fluid.

The history of that waggoner will be remembered, who drove his horses to the last moment, feeling only trifling discomfort, although his pleura contained a very large quantity of fluid (Andral). Landouzy says, do we not see repeatedly during the year, people coming several miles to the hospital on foot, only complaining of trouble in the stomach, or with initial fever—people still at work, and who are the subject of enormous effusions? I have frequently noted analogous facts; and a few months ago I was sent for by my *confère* Dr. Mallet, to the bedside of a patient who only experienced slight oppression of the chest, and in whom paracentesis gave vent to 5 pints of fluid in repeated operations. It is useless to multiply these examples, dyspnoea is a deceptive and untrustworthy guide as is well known, whence I conclude that, to look to oppression of breathing to decide the necessity for performing the operation would be a very grave error.

The error is more serious still, when it is remembered that, unfortunately, instances are not rare of patients being carried off suddenly by syncope or rapid asphyxia, where it had been thought possible to defer paracentesis, the patients having shown so little oppression of breathing. Trousseau gives three examples; in one of these the patient in spite of a large effusion had so little dyspnoea, that the operation was put off for a day, but the next morning death resulted from asphyxia and syncope.

In another case M. Laségue saw a young medical man affected with pleurisy, die before him, while he was preparing to perform the operation. These cases of sudden death, where the effusion is large, are often due to cardiac or pulmonary clots. M. Blachez in an interesting memoir, gives the history of a patient who was suffering from left pleurisy, who succumbed suddenly from syncope, and at the autopsy a clot was found commencing in the pulmonary artery, and which was prolonged until its ramifications to the third and fourth degree. In other analogous cases death has been suddenly caused by thrombosis or embolism of the cardiac and pulmonary vessels. In the works of M. Lacaze-Duthiers, &c., and in

several other publications will be found numbers of cases showing the extreme gravity of cases of large effusion of the pleura, and explaining the causes and mechanism of death in these cases. Louis was, therefore, mistaken in asserting that simple pleurisy is not a cause of immediate death. "Death may result, and suddenly too, in consequence of acute pleurisy with effusion" (Trousseau). This was the opinion of Chomel and Briquet; and of Jaccoud, Peter and Potain as well; and it is the generally received opinion of the day; moreover, it is evident that inasmuch as a large effusion, putting aside the addition of any other complication, may kill the patient, even without any previous dyspnoea, whether from deviation of the heart, thrombosis of the pulmonary artery, cardiac clots or any other cause, it matters little, but I repeat, it is manifest that it is the quantity of fluid effused which should *alone* show the urgency for paracentesis. But it will be objected, given a case of pleural effusion, at what precise moment does dyspnoea become urgent, is it with 5 pints of fluid, or 3½, or 2½? and besides, how will the quantity effused be estimated? how can it be known whether there are 3, 3½, or 4 pints?

In the first place as regards appreciating the time when the fluid by its quantity gives pressing indications for paracentesis, after consulting numerous authorities, I may state that death has never resulted from a less effusion than three-and-a-half pints; in one case, however, of Dr. Blachez's, the pleura only contained two-and-a-half pints of serum. An exceptional case, it will be agreed ought not to serve as a basis for observation, therefore, I consider that in *simple* pleurisies in well developed individuals the necessity for operating will only be shown at a higher figure, viz.: when the effusion amounts to 3 or 3½ pints.

But then another question arises, how can the quantity of fluid be estimated within a quarter or half a pint, what are the signs and what are the symptoms? To elucidate this part of the subject I endeavoured to draw up a comparative table of pleural effusions, hoping to be able to measure or graduate the pleural cavity. For example, if an effusion which reached as high as the sixth intercostal space corresponded to two pints of fluid, one which rose to the third space would be equal to three and a-half pints, and so on. But I met with so many contradictions and encountered so many errors in the supposed estimates of the quantity of fluid that I was compelled to relinquish the scheme. At the same time I foresaw this result; in fact, to succeed in such estimates the sex and shape of the patient must be borne in mind, as well as the form and development of the thorax; for if the pleural cavity of a small thorax is almost filled with two and a-half pints, it can only be partly filled if the thorax is well developed. Moreover, we must also consider the displacement of neighbouring organs, the heart being pushed aside, and the diaphragm depressed, all proving that the valuation of effused fluid can only be arrived at in a general way, and that it varies in each particular case. Then, how can this estimate be arrived at? We are told that small effusions (from twelve ounces to a pint) are characterised, when auscultation of the chest is performed, by a veiled respiratory murmur during expiration and by egophony; that in medium effusions (from one to two and a-half pints) the respiratory murmur acquires a bronchial character, affecting inspiration as well as expiration; and that in large effusions (five to six pints or more) the normal and abnormal sounds may disappear or be replaced by cavernous and amphoric sounds. This is certainly quite true; but, at the same time, what exceptions are met with, and how untrustworthy and insufficient are these results of auscultation in estimating the quantity of fluid effused! And the same with regard to measurements with the cystometer, an excellent method, but not infallible (Woillez). It is therefore absolutely necessary to have recourse to other means, and I believe that the most certain signs are furnished by percussion and by the displacement of the organs, especially the deviation of the heart in left pleurisy. Thus, when dulness reaches posteriorly as high as the spine of the scapula, when obscurity of breath sounds under the clavicle is replaced by abnormally clear tubular sounds ("son skodique"); when, in fact, the pleurisy being left, the apex of the heart beats to the right of the sternum, although the pleural cavity may still not be filled to the maximum; such signs in an adult denote an effusion of three to three and a-half pints, and constitute a formal indication for paracentesis. It matters not that the patient is still in the febrile stage of the pleurisy or that the oppression of breathing is insignificant, we must operate at once without delay, and not forget that procrastination is full of danger, and may cost the patient his life.

I must now remark that we have as yet only discussed simple acute pleurisy which is that most frequently met with; but it must not be supposed that the same principles are not applicable to complicated pleurisy; on the contrary, pleurisy with direct or indirect complications, old adhesions, valvular changes in the heart, pericarditis, pneumonia, in a word, all the lesions which impede the pulmonary circulation or which narrow the field for aération of the blood, far from being a contra-indication to paracentesis, render it imperative so soon as the amount of liquid effused reaches large proportions; but the evacuation of the fluid demands in such case the exercise of certain precautions which will be pointed out further on.

I must also observe that in estimating the quantity of fluid effused, I have chosen as a type what is most generally met with, viz., pleurisy in a well-formed adult; but it must be understood that the indications for the operation remain relatively the same, be the patient young or less developed in the chest, although in this case a smaller quantity of fluid may cause equal danger.

Apart from this question of urgent necessity for operating, the indications for which I have just enumerated, and for which, I repeat, the only safe guide is the quantity of fluid effused, in every other case it is a matter of question; some permitting it, others rejecting it, while some go so far as even to condemn it as harmful. Let us examine these different opinions.

Here is a patient affected with pleurisy, having a moderate effusion of one and a-half to two pints. What is to be done? Shall we adopt a purely medical treatment, repeated blisters, painting with iodine, purgatives, diuretics, sudorifics, &c. ? or is it not preferable to have recourse to the more expeditious treatment by paracentesis? In a word, must we operate? and if so, when? In cases of moderate effusion and where the symptoms are not urgent the problem is always offered in this shape. Although aspiration performed during the febrile state does not appear at all prejudicial to the patient (Moutard-Martin), it is better nevertheless, in the absence of urgency to trust to medical means and to await defervescence before coming to a decision. But defervescence in pleurisy has no fixed epoch; in other inflammations, for instance, in lobar pneumonia, the probable crisis of the fever is known; in pleurisy, on the other hand, nothing is known, and defervescence, sharing as it does the uncertainties of the disease, occurs irregularly from the seventh to the thirtieth day. Moreover, the fall of the fever is far from always being a sign of the diminution of the fluid. Dr. Woillez has very properly insisted on this; the liquid may be absorbed during the height of the fever; and, on the other hand, the effusion may increase although defervescence has occurred. For the rest, do we not daily see cases of so-called latent pleurisy (I do not say hydrothorax), in which the fever subsides unperceived while the effusion reaches considerable proportions? It is therefore necessary to watch the patient and the effusion at the same time, since physical signs and functional symptoms are not always trustworthy, besides attending closely to the period of defervescence often marked by the phenomena of crisis, such as abundance of urine and diaphoresis. When the fever falls the pleurisy is generally at an end, a relic alone remaining—a foreign body, the effusion. Now, if the subsidence of this effusion coincides with the cessation of the fever or with the crisis, or if absorption is progressing favourably, intervention is useless, for in a few days with or without the aid of derivatives or diuretics, its disappearance will be complete; but if, notwithstanding defervescence, the fluid remains stationary, if, after waiting two or three days, its absorption is found to progress slowly or with difficulty, then it becomes necessary to remove this foreign body—this obstacle in the way of recovery—and aspiration must be resorted to.

I have always acted in this manner in dealing with the numerous cases on which this work is based, and I am convinced that this line of treatment has often shortened convalescence by several weeks. It offers still further advantages. Inflammatory products are not allowed to remain in the pleura with impunity, displaced organs will become fixed in their false position, the flattened and sometimes adherent lung becomes impervious or scarcely pervious to air; in short, two of the principal functions of the economy—the aération and circulation of the blood may be compromised for a long time, to say nothing of the transition, in those predisposed, of the inflammation into a chronic state or condition of purulence (Trousseau). Paracentesis practised at the proper time

prevents these drawbacks; and I hope to be able to prove that, subject to precise rules it is absolutely free from danger.

*Résumé.*—Given an acute effusion into the cavity of the pleura one of two alternatives must be chosen. In the first the necessity for operation is urgent: in the second it is open to question.

Urgency can only, and must only be based on an estimate of the quantity of fluid effused, that is to say when the quantity reaches three to three and a-half pints in a well-formed adult.

In the other cases the operation is debatable; to decide the question deservescence must be waited for; and aspiration is only to be resorted to in the event of spontaneous absorption, or this, aided by medical means, proving inefficient.

(To be continued.)

## Special.

FRANCE.

(FROM OUR OWN CORRESPONDENT.)

**FERMENTATION IN THE URINE.**—Another member read a work on fermentation of the urine in a physiological and pathological point of view. The following are the conclusions of his paper:—Atmospheric germs cannot penetrate into the bladder by the urethral canal. Supposing that by catheterism ferment germs entered the bladder, they are not the cause of ammoniacal fermentation of the urine. Bacteria might exist in the urine contained in the bladder without causing ammoniacal fermentation. When the urine becomes ammoniacal the phenomenon is correlative of the lesion, or of the morbid state of some part of the urinary apparatus. Ferments of ammoniacal fermentation can ferment sugar. Ammoniacal alteration of the urine can always be prevented by phenic acid or cresote.

**HYDROPHOBIA.**—M. Pasteur read, at the meeting of the Académie de Médecine, a note upon hydrophobia. Considering attentively the external symptoms of this disease, with certain observations made on the brain of persons or animals who died from hydrophobia, and considering that up to the present the affection has not been communicated by inoculation, M. Pasteur was led to believe that the nervous system, and especially the bulb, were particularly interested and active in the development of the malady. Experiments made by M. Pasteur confirmed him in this opinion. On several occasions, and often with success, he has inoculated the bulb, and even the frontal portion of one of the hemispheres. It results from these experiments that the seat of the virus is not alone in the saliva. The brain contains it, and with a virulence at least equal to that contained in the saliva. Further and more complete experiments on this grave subject will be followed with interest by the profession.

**CALOMEL, QUININE, AND SALICYLATE OF SODA IN THE TREATMENT OF TYPHOID FEVER.**—Before the Société Médicale des Hôpitaux M. Hallopeau advocated the exhibition of calomel, quinine, and salicylate of soda in the treatment of typhoid fever. The anti-pyretic effects of these agents he has fully proved from forty-four cases thus treated. M. Hallopeau commences by giving from fifteen to twenty grains of calomel the first day, to be followed, twenty-four hours afterwards, by ten grains. The second day, if the evacuations be not too frequent, the alternatively sulphate of quinine, at first from twenty to thirty grains, according to the intensity of the reaction, the fifteen grains during three days. Salicylate of soda in the same quantity as the quinine; and so on until the complete cessation of the fever. Salicylate of soda is, however, counter-indicated in the cases where the patients have dyspœa, hæmorrhages, or deliriums. Of forty-four cases treated by this method, there were only five deaths. In almost all the patients the features were but little altered; the tongue remained moist. The strength of the patients was relatively well preserved, and convalescence was not prolonged. The calomel, administered in the doses given above, was observed to lower the temperature remarkably. The quinine was always well borne. M. Hallopeau employs but rarely the cold bath or wet sheet, and only where the temperature resists the reputed anti-pyretic medicines; and he believes

that soon direct refrigeration by cold water will be replaced by anti-pyretics, administered internally, in the treatment of typhoid fever.

**FISSURE OF THE ANUS,** as is well known, causes burning pains, especially at the moment of evacuation. So painful is the affection that often patients abstain from food to avoid the necessity of going to stool, as long as possible. The treatment in vogue to-day is that recommended by Recamier—namely, forcible dilatation of the anus, which severs the concentric fibres of the sphincter. This treatment has always been attended with success; but it has one inconvenience—it is exceedingly painful, and often requires chloroform. To obviate this inconvenience, as much for the surgeon as the patient, Dr. Mascarel, of Mont-Dore, recommends the following treatment, which he has found very successful:—1st. Every day an enema of warm water, with a tablespoonful of glycerine. 2nd. After each evacuation introduce into the anus a small plug of lint, coated with the pomade as follows—glycerine and almond (sweet) oil, of each an ounce; axunge, an ounce and a-half. Before introducing the plug, the *pourtour* of the anus should be coated with the same ointment. Dr. Mascarel affirms that eight times out of ten the fissure is gradually cured after three weeks of this treatment. The beneficial effect of glycerine in certain affections of the rectum, such as hæmorrhoids, fissures, &c., has been of late fully recognised, whether administered internally or applied locally. Your correspondent has prescribed it frequently in teaspoonful doses, three times a day, in painful hæmorrhoids, with the most satisfactory results. The relief was almost immediate. In bleeding piles a little tannin was added, and always arrested the flux.

**OTORRHOEA.**—Dr. Brieson advises, in the treatment of otorrhœa the instillation into the ear diseased of, five times daily, a few drops of a mixture thus composed:—Hydrate of chloral, 45 grs.; sulphate aluminus, 70 gra.; water three ounces. In all the cases cited by the author these instillations have healed the otorrhœa, if not the deafness, in a few days, where no osseous lesion was present. General constitutional treatment is also advised, to prevent a relapse.

**INJECTIONS AGAINST OZÆNA.**—BORAX ʒiiss.; acid salicylic ʒj.; glycerine ʒiiss.; aqua ʒiij. A drachm of this solution in ʒviii. of warm water, to be injected into the nares (*Union Médicale*), or might be used as a gargle in syphilitic ozæna.

## WARD COOLIES.

SUCH is the term by which native attendants upon our sick and wounded soldiers in India have hitherto been designated. And it represents pretty nearly the measure of their qualifications for the special duties required of them. There is no doubt that the description of men usually obtained for the purpose of taking care of our countrymen in Indian hospitals has, for many years back, constituted a decided blot in a system in many respects presenting great superiority over that which prevails even in England; any attempt therefore to effect an improvement in this respect is to be welcomed and encouraged.

In bygone times the manner in which attendants upon sick soldiers were procured was somewhat thus:—The "strength" in hospital having increased beyond that for which the authorised establishment of servants was in due proportion as laid down in the "Medical Code"—a requisition or indent for the additional number and description was sent to the Commissariat, the duty of that department being to furnish all supplies to such establishments. In the majority of military stations a certain number of persons who occupied themselves with job-work, as it may be called in connection with hospitals, were readily to be found; these men, from one reason or another, evinced a partiality to the work required of them, and were content to take employment off and on until such time as they were permanently attached to the establishment of one or other of the regimental hospitals in cantonments. But as to training they had none whatever, save and except what they picked up as to the requirements of sick men by constantly living among them, and seeing what was being done by others. No doubt, some medical officers took much pains in an endeavour to impart something in the shape of technical knowledge to these men, and the Regulations of the service inculcated such

tuition; but, as a matter of fact, the ward coolie was far too apathetic, far too regardless of the importance of the duties confided to him to exert himself willingly in the slightest degree in the acquisition or practice of such knowledge. And so it came about that unless some other help was available, than that of such men, the condition of the unfortunate patient would have been deplorable indeed. Hence arose the system of having in each regimental hospital two or more soldier orderlies in addition to the ordinary native establishments. These orderlies themselves, for the most part, steady old soldiers—we speak now of the days when there were old soldiers—acting under the orders of, and assisting, the hospital sergeant, superintended the ward coolies, saw that they paid proper attention to their patients, and were themselves for the most part, tender and adept as nurses—far more so than it is the fashion of the day to say it is in the province of mere men to be. Nor was this all. Individual patients needing special attention had each a special soldier orderly assigned to him. In the olden times when the existence of *esprit de corps* was believed in, a comrade or friend of the sick man was usually “told off” to the particular duty of attending him, and this duty he continued to perform so long as his services in that capacity were required; then again, patients trivially ill, and those who were convalescent, were expected to, and did, in effect, lend a helping hand in the wards, so that in reality the patients did receive far greater and better attention than might at first sight appear to have been the case under the conditions as stated. There was no conflict of authority; the surgeon nominally under command of the colonel was in reality absolutely independent in all that concerned his own proper sphere; all hospital establishments, including orderlies, coolies, or nurses, were directly under his control, and, as a result, things worked smoothly and efficiently.

When in 1864 Sanitary Commissions were established in the several Presidencies of India, the subject of general hospitals in supersession of regimental was among those early brought before them. In connection with it, a proposal was made that the native establishments of hospitals should be re-organised; but after a number of “minutes” regarding it had been penned, the whole question was shelved, and so continued for several years. In the meantime, new men have arisen, the conditions as previously existing, by which the obvious disadvantages of a system as it existed in theory were neutralised, in fact, were forgotten, and now the question comes up again under altogether altered conditions. With the new “system,” steady old soldier orderlies, *esprit de corps*, comradeship in the ranks, and even association in hospital wards of men of the same regiment are all things of the past. Is it really to be expected that all these conditions, whether actual or sentimental, are to be compensated for by the one novelty, however good in itself, namely, the formation of a Native Army Hospital Corps? Two very opposite replies to this query will be given by officers, according as to whether they are of the old school of experience, or of the new theory.

## Department of Lunacy.

### WONFORD HOUSE HOSPITAL FOR THE INSANE.

ONE-HUNDRED-AND-EIGHTEEN patients were under treatment last year in the Wonford Hospital for the Insane at Exeter, which is a middle-class asylum, with a charitable department, and which evidently meets a pressing want in the West of England. The reports of the Commissioners in Lunacy indicate that the hospital is conducted in no niggardly spirit, and yet the average weekly cost of maintenance is only £1 18s. 9d. per patient. This modest rate of board did not prevent the Committee of Management from devoting £1,302 last year to charitable purposes, two patients having been supported gratuitously, and a considerable number having received grants in aid of maintenance.

Dr. Rees Phillips, the present energetic medical superintendent of the hospital, has introduced many improvements, and now holds in view a comprehensive scheme for the

complete renovation of the interior of the building. Even without any such renovation, however, Wonford House offers excellent accommodation and many amenities to lunatics drawn from the professional classes, who cannot afford the charges of private asylums, but whom it would be cruel to place in association with paupers. The statements formerly made as to the connection subsisting between phthisis and insanity have had to be largely discounted, the excessive mortality of lunatics from consumption in some asylums having been shown to be due to defects in their hygienic arrangements, rather than to any special proclivity of their inmates to lung disease. But still a considerable proportion of lunatics are phthisical, and to some of them, as well as to lunatics who are debilitated by other bodily diseases, the Wonford Hospital offers singular advantages.

Beautifully situated on a rising ground, near Exeter, commanding splendid views over the estuary of the Exe, carefully constructed, drained, warmed, and ventilated, it is a sanatorium, as well as an asylum; and might become a special health resort for lunatics, for whom the salubrious climate of South Devon was judged to be a desirable adjunct to treatment.

### LUNACY DISTRICTS (SCOTLAND) BILL.

THE following are the terms of the Lord Advocate's Bill, introduced into the House of Lords, “to make provision for altering and varying lunacy districts in Scotland” :—

Whereas by the forty-ninth section of an Act passed in the Parliament held in the twentieth and twenty-first years of Her Majesty's reign, intituled “an Act for the regulation of the care and treatment of lunatics, and for the provision, maintenance, and regulation of lunatic asylums in Scotland,” it was enacted that with a view to the erection of asylums for the reception and care of pauper lunatics, and for the purposes of the said Act, Scotland should be divided into districts or divisions as set forth in a schedule thereto annexed, and that the General Board of Commissioners in Lunacy should have the power, on the application of the Prison Board of any county interested, to alter or vary said districts, either by combining counties, or otherwise, as they might think fit: and whereas by the operation of the Prisons (Scotland) Act 1877, Prison Boards in counties have ceased to exist, and there is no existing legal authority having the power to make such application for altering or varying the said districts: be it therefore enacted, &c. :—

1. The Lord Advocate shall have the power, on the application of the General Board of Commissioners in Lunacy for Scotland, to alter or vary the said districts, either by combining counties or parts of counties, or dividing counties, or otherwise, as may be requisite.

2. This Act may be cited as the Lunacy Districts (Scotland) Act, 1881, and shall be construed together with the first-recited Act.

### THE CAUSES OF INSANITY.

In his recently-issued Report on the Derby County Asylum at Mickleover, Dr. Murray Lindsay, the indefatigable Medical Superintendent of that institution, dwells on the importance of ascertaining the causes of insanity in each case not merely as a matter of scientific interest, but as a guide to treatment. The difficulties which are generally alleged to obstruct such inquiries are not, in Dr. Lindsay's experience, insuperable. In 154 out of 158 admissions into the Asylum during 1880—that is to say, in all but four cases—histories

more or less complete were obtained from relatives, friends, or relieving officers, the result being that in all but sixteen cases, definite causes of insanity were satisfactorily ascertained. This large measure of success in etiological investigation was mainly due to the intelligent co-operation of relieving officers taking an interest in their work and responding willingly to the wishes of the Asylum medical staff. By their endeavours, and from information derived from other sources, Dr. Lindsay feels justified in concluding that an hereditary predisposition to insanity existed in 34 per cent. of the patients admitted last year. In 20 per cent. there had been previous attacks of insanity, which is significant as showing the liability to a recurrence of mental disease after the mind has once been disordered, and the instability of what are called cures. Epilepsy was the ascertained cause of insanity in 15 per cent. of the cases admitted, and intemperance in 13 per cent. The latter cause of insanity was responsible for the mental disease in 18 per cent. of the cases admitted in 1879, the slight reduction in its morbid influence being coincident with a slight revival of trade in Derbyshire.

#### SALINE AND TABLE-WATERS.

We have now to do with an important class of waters. They are those which have generally been classed under distinct heads, namely, saline, (waters owing their chief efficacy to salt) faintly alkaline waters, and indifferent waters. Now, we prefer to class all these waters under one head—it is immaterial to us what the exact analysis may give; it is evident that as regards classification we must consider them from the point of view of their application, the justification of the application being determined by the analysis. If they are used as a table water, or a food product—they are certainly equally important, we may say, *more* important than other waters, because of the very large quantities consumed.

#### SELTZER.

The most important of such waters we give first. Advertisements may have done a great deal, quality has done something, but no water has been able to displace seltzer water as regards its hold on the public mind, and its position as a natural table water. It is the one which has been the type of artificial table waters. The consideration also of seltzer water will justify us in a system for the first time adopted in these articles, of keeping the salines, such as chloride of sodium distinct in our classification from the strong purgatives such as

sulphate of sodium. It has been pointed out in the therapeutics of our work, that even water itself may be viewed as an aperient under certain circumstances. It is not practically so, however, when drunk at the table with our meals, and the same may be said of salines such as chloride of sodium. We could have no better illustration of this than the very general use of seltzer water, which if it acted at all energetically as an aperient, would not be in use as a table water. These remarks must be always borne in mind, in considering the analyses of table waters, the presence of rather large quantities of chloride of sodium, is no detriment providing the sulphates of magnesia and soda are low. The seltzer spring contains nearly 200 grains of chloride of sodium but very little sulphate of sodium and no sulphate of magnesia.

It is perhaps not too much to say that the most celebrated waters perhaps in the world are those obtained at the small post town called Selters, a short distance from Schwalbach. Although we have never been at that town we think we are justified in stating that the spring or springs are not used as baths, and that it is entirely consumed in bottles for home and export consumption. Murray, in 1876, stated that a million and a half of bottles were exported annually, and that the quantity was increasing. We can readily believe that the consumption of this water has been even further increased owing to the extensive use of it as a table water. Although, strictly, a mild saline alkaline water in its natural state, its piquant flavour is increased by the addition of salt which brings its solid ingredients up to 297 grains, the added salt is nearly one half of the entire solids.

The antacid properties of this water are largely due to the alkaline earths, and the consequence is, that it does not present any marked alkaline reaction with phenol phtalein even after prolonged boiling. Still it does exhibit a slight alkaline reaction, particularly

if warmed. The water as examined by us differs very considerably from the published analysis, more particularly as regards the smaller amount of alkaline carbonates, and the presence of chloride of magnesium, which is ignored in the other analyses.

WEDNESDAY, JUNE 22, 1881.

### THE INTERNATIONAL MEDICAL CONGRESS.

THE arrangements made with respect to the forthcoming International Medical Congress may now be considered as fairly complete, since there will be probably only a few alterations in the programme as it stands at present. The principal change made from the original scheme has been necessitated by the conditions under which the ex-officio presidency of the Council falls by right to the head of the College of Physicians, Sir William Jenner replacing Sir Risdon Bennett in both capacities, consequent on his election to the presidential chair of the premier medical corporation of the kingdom. The pathological section will be presided over by Dr. Burdon Sanderson, a fresh appointment to this important office having been rendered necessary by the lamented decease of Professor Sanders, of Edinburgh. Death also has removed one of the vice-presidents of the meeting in the person of Dr. Hudson; and a vice-president of the section of anatomy in the person of Dr. Rolleston, of Oxford. It is sad, indeed,

even while the time at which the Congress is summoned to meet is yet some weeks ahead, to have to record these heavy losses; and all who had anticipated an association with the distinguished men just named will be painfully reminded of the calamity their loss occasions, during the time when by their absence they will be mournfully conspicuous. Notwithstanding, however, there is every reason to hope and believe that the Congress will be a most successful demonstration of the dignity and importance to which the science and art of medicine and surgery have attained. There is already rich promise of ample discussion on subjects of interest and importance, and the names of many foreign visitors who have engaged to attend the Congress is an earnest of the additions likely to be made to our scientific knowledge, as a consequence of the meeting. Possibly there has never been witnessed in this country the assembling together at any one time of a like number of eminent and learned men, as will assuredly congregate in St. James's Great Hall on Wednesday, August 3rd, when the President of the Congress, Sir James Paget, will deliver his inaugural address. The interest of this, the first day of the meeting, will culminate in Sir James Paget's oration, and on the succeeding days we shall look for such special communications to be read before the various sections, as will be likely to bear plentiful fruit in the future development of our knowledge. These sections are fifteen in number, and relate respectively to anatomy, physiology, pathology and morbid anatomy, medicine (sub-section diseases of the throat), surgery, obstetrics, diseases of children, mental diseases, ophthalmology, diseases of the ear, diseases of the skin, diseases of the teeth, State medicine, military surgery and medicine, and materia medica and pharmacology. It says much for the energy and devotion of the committee of management appointed to arrange the details of the meeting, that in every section a prospectus of the subjects suggested for treatment in connection with it has been drawn up, printed in three languages, English, French, and German, and communicated to all medical practitioners in Europe and America likely to be interested in the various branches dealt with. The syllabuses, too, have many of them a high value as indicating the lines along which special research is required for the elucidation of points as yet not fully explained. Of course the task of preparing these outlines has been accomplished for each section by the officers appointed to carry out the work falling to it; but none the less we feel it will be universally considered that unqualified praise should be bestowed on the honorary secretary-general, Mr. McCormac, to whom especially has fallen the work of superintending the systematic execution of the whole stupendous undertaking. Much of the harmony with which hitherto the work of the committee has been accomplished is undoubtedly due to this gentleman's active and unceasing devotion to the cause he has espoused; and we can heartily record our own appreciation of the value of his exertions and the influence they have exerted in determining the great result to be achieved.

England has earned among Continental and American members of the medical profession a reputation for genial hospitality which it will be essential for us to maintain on this occasion. The number of strangers who will certainly

visit London for the purpose of taking part in the coming Congress will be very large; and the finding accommodation for these is a matter of anxious consideration with the executive committee. That, many as there will be, all will find a welcome with those who are prepared to receive them with the most friendly feelings, is probably certain; but, notwithstanding, the unusual circumstances surrounding the occasion may prove a severe test to the powers of the committee. For this reason they will gladly receive offers to entertain guests from all who have not as yet engaged to do so, and may be willing to extend the hospitality of their homes to any of the expected visitors for the week. The hint will be, we are convinced, more than sufficient, and we hope to find that only a very few who come to England expectant of the warm greeting of which so much has been said and written, will be disappointed by the result of their visit.

A number of entertainments and excursions are already announced as arranged for others will, doubtless, be yet provided for, and we have every reason to anticipate an unequalled success in every respect, as a result of the great International Medical Congress of 1881.

#### AN IRISH POOR-LAW WIDOW AND ORPHAN FUND.

It is several years since the proposal to establish a fund to provide annuities for the widows and orphans of Irish Poor-law medical officers was started at a general meeting of the Irish Medical Association, by Dr. Darby, of Bray. The suggestion having been then approved and adopted by the meeting, was submitted to an actuary for the purpose of obtaining from him an opinion as to the amount of the deduction from the salary of the medical officer which would be required in order to provide suitable pensions.

The report thus obtained was not conclusive, and the subject fell into abeyance for a couple of years, when it was taken up by Dr. Jacob, who sent out circulars throughout Ireland for the purpose of obtaining reliable statistics, and upon the figures thus calculated built up a scheme, which he put in pamphlet form, and afterwards published in our columns. Dr. Jacob's proposal was that each Poor-law medical officer should be asked to sign a document, authorising the Council of the fund to stop a small sum each quarter out of his salary, which deduction was to be collected from the Local Government Board, and stopped by the Board from the grant made by the consolidated fund to the union in which the contributing officer resided.

It will be observed that this scheme contemplated the bringing of the younger Poor-law medical officers within its provisions by means of a voluntary mortgage on their salaries. The proposal was submitted to the Irish Medical Association, and was also submitted to an actuary, who gave it as his opinion that no arrangement would be safe and practical, which did not make the contribution to it compulsory, because it might be expected that a voluntary fund would be gladly availed of by the elderly men, with wives and children, for whom they had made no provision, while the younger and more healthy men, who had neither wives or children,

would stand aloof. Thus the class of contributors, with long life before them, and no uxorial responsibilities, would be lost to the fund, while it would be immediately laden with claims arising after the death of contributors, who joined it when advanced in life. When this opinion was given by the actuary, employed by the Association, there was no precedent in Ireland for a prosperous widows and orphans scheme, and, thereupon, the question passed a second time out of notice, and so remained until the past year, when Dr. Jacob reopened the subject under more encouraging conditions. In the interval a similar fund had been established, and satisfactorily worked in connection with the Irish Church, the calculation upon which it was based, having been fully worked out under the auspices of the General Synod, and the scheme thus matured was adopted as a safe basis for the Poor-law medical fund.

Having examined the Act of the General Synod for the management of its fund, the following Bill of a similar character was prepared and submitted first to the Executive Committee of the Irish Medical Association, next to the Council, and afterwards to the general meeting of the Association itself, and it has been approved by all three bodies.

#### A BILL TO ESTABLISH A FUND FOR MAKING PROVISION FOR THE WIDOWS AND ORPHANS OF MEDICAL OFFICERS OF UNIONS IN IRELAND.

Whereas it is expedient that medical officers of unions in Ireland should be enabled to make provision for their widows and orphans by periodical contributions to a fund to be established for that purpose.

Be it therefore enacted by the Queen's Most Excellent Majesty, by and with the assent of the Lords and Commons, and by the authority of the same, as follows:—

1. This Act may be cited as the "Union Medical Officers' Widows and Orphans Fund (Ireland) Act."
2. Under the provisions of this Act a scheme for the establishment of a fund, to be called the Union Medical Officers' Widows and Orphans Fund may be submitted to the Local Government Board for Ireland, and that Board, if it shall approve of the terms of such scheme, may make an order declaring that such scheme shall be carried into effect: and, thereupon, such scheme shall take effect, and be as binding as if its provisions were herein enacted.
3. The Council of the fund may, from time to time, alter or revoke, or add to the provisions of the scheme, provided that such alteration, revocation, or addition, shall be approved by the Local Government Board for Ireland, and shall not be inconsistent with anything contained in this Act. Every alteration or revocation of any provision of the scheme, and every addition thereto shall be laid before the contributors to the fund at their first general meeting after the adoption of same by the Council, and before same is submitted for the approval of the Local Government Board for Ireland; and the contributors may, thereupon, rescind and annul such alteration, revocation, or addition.
4. The Council of the fund shall, on or before the first day of March, June, September, and December, in each year, furnish to the clerk of each union in Ireland, in which a contributor to the fund is entitled to receive either salary or superannuation allowance, an account setting forth the quarterly contribution, which such contributor is liable under this Act to pay to the fund, and the clerk of such union shall, thereupon, be entitled to deduct, and shall deduct such amount from the next quarterly payment to be made by him to such contributor, and shall hand over such deduction to the trustees of the fund.

*Classes of Contributors.*

5. Every medical officer of a union in Ireland who, after this Act shall have come into operation, shall enter into the Poor-law service for the first time, or who, having left the said service, shall be again appointed to the same, and who on entering or being again appointed shall not be more than [40] years of age, and shall be unmarried, or a widower without children, shall be required to contribute [£6] per annum to this fund.

6. Any other medical officer of a union in Ireland may be admitted as a contributor to this fund upon such terms as the Council, with the advice of an actuary, may determine.

*Benefits to Widows and Orphans.*

7. The widow of every contributor shall be entitled to receive an annuity of [£33], to terminate absolutely on remarriage; provided (a) that her husband, at the time of his death, held office in the Poor-law medical service of Ireland, or was in receipt of superannuation under same, or had continued to make payment of an amount equivalent to the deduction from his salary as provided in clause 10 of this Act; (b) that, at the time of marriage, he was under [60] years of age; (c) that he was not more than [25] years older than his wife; (d) that they were married for at least one year before his death; and (e) that the contribution to which such contributor was liable was paid up to the last term day before his death.

8. Every orphan whose mother is, or should have been, if living, entitled to an annuity on her husband's death, shall be paid an annuity of [£5] each until he or she attains the age of 21 years, or in the case of a girl, until she marries, if before that age; provided no more than [£25] per annum shall be paid to any one family orphans.

9. In cases where orphans are afflicted with any mental or bodily infirmity, rendering them incapable of supporting themselves, the Council may continue the payment beyond the age of 21 years.

10. If a medical officer who is a contributor under section 5 retires from the Poor-law medical service, his widow and orphans shall, after his death, be entitled to the benefits of this fund if a sum equivalent to the deduction from his salary is paid, during his life, to the Council.

11. In case any member of the fund shall, for any cause, vacate his Poor-law office, and shall not be in receipt of superannuation allowance in respect thereof, and shall be unable or unwilling to continue, under clause 10, his voluntary subscription equivalent to the deductions from his salary, then the Council shall at his death, award, as annuity, to his widow and orphans a sum less than that set down in clauses 7 and 8 of this Act, in proportion as the member's payments are less than he should have made; but they shall not refund to the member, during his life, any part of the sums deducted from his salary or voluntarily paid by him.

12. In case any member shall marry more than once, he shall—in order to recoup the Fund for the probable increase in the time of survivorship of his widow and orphans—authorise the Board to receive, from the date of each such marriage after the first, an increased deduction from his salary, the amount of which shall be decided by the Board.

*General Provisions.*

13. The annuities shall be payable quarterly, on every 1st day of January, 1st day of April, 1st day of July, and 1st day of October, and the first quarterly payment of an annuity shall be paid upon the gale day next following the death of the medical officer upon whose death it becomes payable.

14. All moneys or other property accruing to the funds, whether from contributions, as hereinbefore provided, or from bequest or donations, or from interest or other profits derived from investments, shall be vested in three trustees, who shall be elected every five years

by the contributors in general meeting. All annuities and other charges payable under this Act shall be paid out of such monies, and any sums which may remain in the hands of such trustees after such annuities and charges have been satisfied, shall be placed to the credit of the reserve fund.

15. The reserve fund shall be invested in such securities as are approved by the Court of Chancery for the investment of trust funds.

16. The Council shall have investigations of the state of the fund made by a competent actuary at the end of every five years, and they may increase, or reduce the annuities payable under this Act, to such extent as in their opinion shall be expedient. If it shall then appear that the moneys in the hands of the trustees are more than sufficient to satisfy all present or future liabilities of the fund for annuities and expenses of management, the Council may order that the interest arising from the reserve fund and of such grants or donations, unless otherwise appropriated by the donors, shall be applied to reduce the contributions or to increase the annuities in such manner as may be determined on, from time to time, by the Board, with the sanction of the contributors.

17. The Council shall report to the contributors at least each year, and publish a statement of finances at each general meeting.

It will be observed that, if this Bill is approved by Parliament, every Irish Poor-law medical officer will, *ipso facto*, on joining the service (or rejoining it if he already held office therein) be subject to a small quarterly deduction from his salary. Officers already in harness may also place themselves within the scope of the fund if accepted by the Council, but the amount of the deductions from the salaries of such officers will vary according to their ages, condition of health, and condition as regards marriage and paternity. Once an officer becomes a contributor he will know no more about the transaction except that his quarterly cheque for salary will be slightly less than the full amount. The Council of the Fund will collect the money from the clerk of the union and invest it, and thereout will pay after his death a fixed sum to his widow and children who survive. Thus the contributions by the medical officer who leaves no widow or children chargeable on the fund will go to help the widow and orphans of his professional brother who leaves behind him those for whose maintenance he was responsible.

A handsome reserve is, of course, an essential element in the safety of such a scheme, because without such reserve an unusual mortality amongst its contributors might produce insolvency. But there will be, under the proposed arrangement, such a fund. For many years after its first starting there would, probably, be no demand at all upon the fund, because all the contributors would be young men, in rude health, possibly unmarried, or with only one or two children. During these years the contributions to the fund will be laid by untouched and will bear substantial interest, and it is calculated that these accumulations will yield a capital of £10,000 before the period arrived at when the claims on the fund would equal its income. The amount of the deduction from salary to which the medical officer would have to submit is an important factor in the settlement of this question, and it must be at once understood that as yet nothing has been decided on this point. The figures printed in the foregoing Bill are those to which the Irish clergy have bound themselves, and it may be taken for granted that the con-

tributions and the pensions are proportioned to each other on sound financial principles, and on the best actuarial advice. But for Poor-law medical officers these amounts may be fixed at any scale, so long as the proportion remains the same, and it will, of course be a subject for careful deliberation what deduction from salary can be afforded by the average Poor-law medical officer, and what is the least pension that ought to be secured to his widow and orphans. In connection with this aspect of the scheme it ought to be closely borne in mind that the proposed fund does not at all aim either at forestalling the necessity for life insurance or at superseding the benevolent work of our valuable organisation the Royal Medical Benevolent Fund. On the one hand it must be recollected that the best pension which could possibly be granted to a widow or orphans in respect of a deduction from salary at all reasonable would be altogether inadequate as the sole support of the pensioners. It would be a valuable help, and would make for them the difference between penury and moderate comfort; but it would be, at least, only the supplement of other income which may be hoped for from insurance or accumulated property; on the other hand, the pensions granted could never do away with the Royal Medical Benevolent Fund, or do more than relieve it of the excessive strain upon its resources. There would always be many claimants to whom charitable help was a real necessity, and we should hope to see the day when these two organisations would work side by side to rescue the widows and orphans of Irish medical men from indigence.

This scheme has been submitted to the Irish Local Government Board, and has, in principle, received their approval, and we have every hope that, before long, its details may be fully matured and parliamentary sanction obtained for it.

## Notes on Current Topics.

### Royal College of Surgeons, England, Annual Election.

THE annual election of Fellows of the Royal College of Surgeons, to fill the vacancies occurring in the Council, will take place on the first Thursday in July. The time by which nominations had to be sent in expired on the 13th inst., and there are now announced for the three vacant seats the following gentlemen:—Sir James Paget and Mr. Haynes Walton, who offer themselves for re-election; Mr. J. W. Whittaker Hulke, F.R.S., Surgeon to the Middlesex Hospital; Mr. Christopher Heath, Surgeon to University College Hospital; Mr. John Croft, Surgeon to St. Thomas's Hospital; and Mr. Reginald Harrison, Surgeon to the Liverpool Infirmary. All the gentlemen named above are Fellows of the College by Examination. The election will take place at 2 p.m., on Thursday, the 7th of July. It should be mentioned that at the election last year, when Mr. Cadge, of Norwich, was a successful candidate, Mr. Harrison, of Liverpool, would have presented himself, in obedience to the wishes of numerous provincial surgeons, but for a desire to present no obstacle to the election of Mr. Cadge. The representation of the

provincial branch of the surgical profession is by no means at present as considerable as should be the case, and it is to be hoped that those who wish to see Mr. Harrison returned will make an effort to secure so desirable a result. Mr. Harrison's fitness for the honour he is seeking is unquestionable, and we wish him all the success in his candidature he so eminently deserves.

### Death of Prof. Skoda.

THE well-known Vienna Professor of Medicine, Joseph Skoda, died on Monday the 13th inst., at the age of 75. He had been ill for a considerable time, and no hope of his recovery had been entertained. The labours of the deceased physician in connection with pathological changes in the thoracic viscera, are sufficiently well-known and appreciated to make his death a subject of general regret; while the generous gifts made by him in the later part of his life in aid of the families of medical men, will serve to excite grateful recollections of his goodness. Skoda was undoubtedly one of the greatest teachers of the Vienna School, and to him in no inconsiderable measure is due the high position it occupies at present as a centre of medical instruction. He was compelled, some years ago, by frequently recurring and painful attacks of gout, to resign his post as Professor of Clinical Medicine at the General Hospital of Vienna, but there are many men in this country and America who will preserve kindly recollections of the amiability and harmony which distinguished him.

### Storage of Electricity.

THE application of the electric light in medicine is attracting a considerable amount of attention just now in connection with the employment of the Faure battery, by aid of which, what is called *storage* of the electric fluid, may be accomplished. According to Sir William Thompson (*Nature*, June 16), Reynier's statement that an accumulator (Faure's) weighing 165 pounds can store up and emit again 2,000,000 foot pounds of energy, is confirmed by fresh observations. He continues, "I have not yet succeeded in making the complete measurements necessary to say exactly what proportion of the energy used in charging is lost in the process of charging and discharging. If the processes are pushed on too fast there is necessarily a great loss of energy, just as there is in driving a small steam engine so fast that energy is wasted by 'wire drawing' of the steam through the steam pipes and ports." Slow action, too, is attended with some loss, but the escape from local action may, Sir William thinks, be reduced to a small amount. He considers that accumulators weighing three-quarters of a ton, will suffice to work a single charge for six hours at the uniform rate of one horse power, and with a loss of only ten per cent. of the charge. These results are interesting to the profession, for if they are verified by application to heavy work, the question of modifying the apparatus for medical purposes is simply one of mechanical ingenuity. Prof. Tyndall, in a letter to the *Times* of Saturday last, denies the accuracy of the explanation given by Sir William Thompson respecting the action of the "accumulator." According to him there is no actual "storage" of electricity, but the machine acts as a constant battery. **D**

this as it may, however, the usefulness of the discoveries already made, and their possible applications in the future, would appear to be all but demonstrated, and this, irrespective of scientific controversy, is a matter on which we may well congratulate ourselves.

#### The British Association.

THE British Association for the Advancement of Science will hold the 1881 meeting at York during the week ending September 8th next. Peculiar interest will attach to it by reason of its being the jubilee of the Association, and also from the fact that the first meeting in 1831 was held at York. In order to celebrate the event a special exhibition will be held, in connection with the meeting, of instruments and scientific tools, to illustrate the advances made during the past half century. Men of science, societies, and manufacturers are invited to lend articles for exhibition; these will be insured by the Association, and carefully preserved and returned to their owner.

#### The Harveian Oration.

ON Saturday last Dr. A. Whyte Barclay delivered the annual oration commemorative of the life and work of the discoverer of the blood, before a large and select meeting of the medical profession at the Royal College of Physicians. Sir Wm. Jenner, President of the College, occupied the chair. The address was like most of its predecessors, a laudation of Harvey's great achievement, and was an eloquent and able composition. We venture to think, however, that the time has come when these annual lectures should be something beyond a modified obituary notice, and take the form of a contribution to our higher knowledge. Will no one take the hint?

#### Fish for Food.

THE publication of the truth concerning the scandalous manner in which the Metropolitan fish market is "rigged," and a large amount of highly nutritious and wholesome food thus lost to the public, has done a considerable amount of good, and may be expected to result in a reform of the abuse that has been permitted to grow up in connection with the subject. Most persons are acquainted with the fact that a fish diet is a safe and desirable substitute for coarse meat, which can be advantageously resorted to at frequent intervals. As supplying the material for restoring tissue waste in those whose brains are overtaxed in city pursuits its value cannot be over-estimated, nor as a staple article of consumption among the poorer classes would fish compare unfavourably with whatever is most usually consumed by them. Hence the knowledge that it is to be regarded as a luxury rather than as a common article of diet, because of the avarice of those whose interest it is to maintain a fictitious value for it, reasonably forms a subject of complaint with the public generally. The question of the indignation felt against the fish-brokers is further intensified by the assertion, hitherto uncontradicted, that a daily destruction of tons of fish goes on, simply to maintain high prices, and this in a city where thousands of poor are daily suffering the pangs of hunger. It is safe to assume that no other country in the world would tolerate such gross injustice, and it adds no palliation that the

object of the iniquity is the enrichment of some few dealers whose common honesty is too feeble to rebel against the wrong they are committing.

#### Act Relating to Colour-Blindness.

THE following Act has been passed by the Legislature of Massachusetts and approved by the Governor:—

SECTION 1. No railroad company shall employ or keep in its employment any person in a position which requires him to distinguish form or colour signals, unless such person, within two years next preceding, has been examined for colour-blindness or other defective sight, by some competent person, employed and paid by the railroad company, and has received a certificate that he is not disqualified for such position by colour-blindness or other defective sight. Every railroad company shall require such employé to be reexamined at least once within every two years, at the expense of the railroad company.

SEC. 2. A railroad company shall be liable to a fine of one hundred dollars for each violation of the preceding section.

SEC. 3. This Act shall take effect on the first day of July next.

#### Trichinæ in Meats.

THE *Progrès Médical* reports that Mr. Pouchet has made experiments in his laboratory, on three rats, which he fed on both salted and smoked trichinous meats. On dissecting those animals, he found no trichinæ cysts in their muscles, but great quantities in the intestinal cavity, showing no signs of having been acted on. He therefore concluded that those meats were not dangerous.

Mr. Bert says that pickling, when recent, does not kill trichinæ, but that after a time they die of their own accord in salted meats, in the same way as they die in the human muscles. How long does it take to bring about this result? From experiments made in Denmark, it would seem that from one to three or four months are necessary. The fact is, this point is still in darkness, and it is the more to be regretted that there exists no reliable method by which it is possible to ascertain whether trichinæ contained in meats are alive or dead.

#### Death of Dr. Otis, of America.

DIED at Washington, on the 23rd of February, æt. 50, George Alexander Otis, M.D., Surgeon U.S.A. Dr. Otis, who is widely known as an eminent writer on military surgery, and as the compiler of the surgical volumes of the Medical and Surgical History of the War, was born at Boston, Massachusetts, November 12, 1830; he graduated in the Arts at Princeton College, and in Medicine at the University of Pennsylvania, in 1860. He then visited Europe, and prosecuted his studies in London and Paris, and, returning to this country, he began the practice of his profession at Springfield, Massachusetts. He entered the army as Surgeon of the 27th Massachusetts' Volunteers, in September, 1861, and after the close of the war, he entered the medical corps of the regular army.

DR. FARQUHARSON will move the rejection of the Vivisection Abolition Bill, which stands for reading on Wednesday, July 13th.

### Syphilis Propagation.

IN reply to Mr. O'Kelly, Mr. Forster stated in the House of Commons, last week, that it was not intended to apply the Contagious Diseases Acts to Dublin. The more the pity! No city has greater need of some means of checking the ravages of venereal disease. But probably the Chief Secretary has enough on his mind without invoking the virtuously indignant protests of the few but very talkative goody-goodys who constitute the anti-contagious diseases party in Dublin.

### Abnormal Muscular Development.

DR. R. W. CORWIN, of Chicago, held a post-mortem over a very muscular Bohemian, killed by accident last October, and found in the right pectoral region a muscle about seven inches long, two and one-fourth inches wide, and one-third of an inch thick, lying nearly at right angles to the ribs, having its origin by aponeurotic fibres from the lower border of the sternal end of the second rib (some of the fibres piercing the pectoralis major), and its insertion by an aponeurosis in the lower anterior border of the pectoralis major. No trace of a similar muscle could be found on the opposite side.

### Artisans Dwellings.

SIR RICHARD CROSS has, after considerable delay, secured the appointment of the Select Committee on Artisans' and Labourers' Dwellings. The members are, besides the right hon. gentleman, Mr. Courtney, Sir S. Waterlow, Sir M. Ridley, Mr. W. Holms, Mr. Brodrick, Mr. Torrens, Sir H. Holland, Mr. Bryce, Sir J. McGarel Hogg, Mr. Cropper, Viscount Emlyn, Mr. F. Buxton, Mr. A. Balfour, Mr. Hastings, Mr. Rankin, Mr. Brand, Mr. Leamy, and The O'Donoghue.

### The Health of Ireland.

IN the year which ended on the 31st of December last the number of deaths registered in Ireland amounted to 102,955—51,671 males and 51,284 females—equal to a ratio of 19.3 per 1,000 of the population, being 1.5 per 1,000 persons over the average rate for the ten years 1870-79, the mortality being the highest recorded in any year since registration was established in 1864, except the year 1876, when the rate was 19.6.

During the year, 11,750 deaths were returned by the registrars as having occurred from the eight principal zymotic diseases, being 11.4 per cent. of the total deaths, and equal to 2.21 in every 1,000 persons living. The average annual number of deaths from these diseases during the previous ten years was 11,125, or 2.08 in every 1,000 of the estimated average population, the lowest number during that period being 9,162 in the year 1877, and the highest 14,216 in 1872; the number registered during the year 1879 was 9,895.

Of the 11,750 deaths from these diseases last year, 369 (266 of which occurred in Dublin and its suburbs) were caused by small-pox, showing a decrease of 303 as compared with the number in the year 1879; 979 by measles which in the preceding year caused 860 deaths, and in the year 1878 2,212; 2,350 by scarlet fever, being 662 in excess of the number for the year 1879, and 1,371 ver

the deaths in the previous year, but still 12 under the average for the ten years 1870-79; 289 by diphtheria; 2,199 by whooping-cough, being 461 over the average for the ten years 1870-79, and 16 in excess of the highest yearly number in that decennium; 2,986 by fever, being somewhat over the number in any of the preceding five years, but slightly under the average for the ten years 1870-79; 2,518 by diarrhoea, a number considerably over the average; and 60 by simple cholera.

The births registered during the year number only 128,010, affording a ratio of 24.0 per 1,000, against an average rate of 26.6 per 1,000 for the previous ten years.

### Sickness Caused by Putrid Meat.

AT a recent meeting of the Michigan Board of Health, a letter was presented from Dr. Mulvany, M.D., of the British Navy, detailing the effects of food rendered unwholesome through putrefactive taint. All of the crew of a large merchant vessel that put into the Falkland Islands who ate of pork, opened on a certain day, became ill, and the illness continued until the ship was disabled and medical assistance was sought for in the Falkland Islands. There it was found that not only the pork but the beef was bad, and the meat was condemned by a board of surveying officers. Seven of the affected died, and post-mortem examination revealed immense effusion into the pericardium, a stench from the brain and congestion at the point of the calamus scriptorius in the fourth ventricle, with congestion of the jejunum and ilium. During life the chief symptoms were paralysis of the hands and feet, and agonising pain in the toes; uncontrollable sleeplessness, loose bowels; stench from the skin, etc. Symptoms entirely *sui generis*. The Board requested Dr. Mulvany to present a complete account of the sickness.

### Alcohol—Clinical Phases of Poisoning.

DR. WOODBURY (*Philadelphia Medical Times*) makes the following points on this subject:—(1) Acute alcohol poisoning, manifesting itself in the forms of coma, convulsions and mania-a-potu, is characteristic of the physiological action of alcohol upon a system unaccustomed to its use. Its treatment in cases of coma and convulsions is like that of the other narcotic poisons producing paralysis of the respiration, but in mania powerful cerebral sedatives are required. During the after-treatment alcohol is not necessary, but on the contrary, every encouragement, both by precept and by prescription, should be given the patient to adopt total abstinence as his only chance of safety. (2) Chronic alcoholic poisoning, exhibiting itself in the form of horrors, vigilance, delirium tremens or melancholia, on the contrary bespeaks the existence of a depressed condition of the vital powers due to saturation of the system with alcohol and consequent degenerative changes. Such unfortunate cases, suffering from what might be called an alcoholic diathesis, require careful nursing, a supporting treatment and the continuance of stimulants, which to them have become both food and drink.

MR. WARTON, the House of Commons bore, has given notice of his intention to move the rejection of Mr. Litton's Lunacy Law Assimilation (Ireland) Bill.

### Excision of the Pylorus.

SOME time ago we drew attention to the performance, by Billroth of Vienna, of excision of the pylorus in a woman affected with cancer of the part. This, the first operation of the kind, did remarkably well, union occurring rapidly and completely, and terminated in complete recovery from the immediate effects of the severe proceeding. The operation was undertaken in January last, and all continued well until about a month ago, when symptoms of anorexia set in, and proceeded rapidly until the woman succumbed. The success of the operation has, however, been thoroughly well testified, and it has since been repeated several times, but with success in only a small proportion of the cases. Whether it will become generally adopted must, of course, depend on the results obtained from it in a large number of hands; that it is feasible and fairly safe may, even now, be accepted as proved.

### Liebig's Extract.

THAT this preparation has lost nothing of its popularity may be judged from the fact that the Company in their fifteenth annual report, report sales during the year amounting to £141,137. This comprises sales of extract of meat, hides, tallow, horns, &c. The net profit amounts to nearly £70,000, which allows for the usual 10 per cent. dividend and £15,000 to be carried to the reserve fund. The company own about 37,000 head of cattle, and they have lately purchased about 27,000 acres more of grazing land in Uruguay for £18,419, and have taken on lease 52,149 acres more land, so as to be able to increase their cattle stocks.

### The Unqualified Assistant System.

OUR contemporary the *Globe* says:—"Not a moment too soon, a raid has been proclaimed in the Midland counties against the unqualified medical practitioners who there abound. The evil has now reached dimensions which render united action on the part of the faculty imperatively necessary, if any good is to come from the present agitation. So far, the enemy has prospered, chiefly by reason of dissension in the opposite camp. At a late meeting of the Midland Medical Association it was affirmed that many members of the profession have actually been in the habit of joining in partnership with unqualified practitioners. Others it is asserted, allow their names to be used by these untrained practitioners, while, in some cases, practices have been sold to them by retiring doctors. As was well said by one speaker, these doings really amount to a fraud on the public by causing them to imagine that they are being attended by skilled experts, when in reality they are in the hands of ignorant empires. Another evil is, that when poor patients who have been attended by the unqualified partner die, the one possessing the qualification signs the death certificate, although he may never have seen the deceased.

### Maintenance of Irish Lunatics.

MR. O'SHAUGHNESSY has given notice that on Thursday next he will ask the Chief Secretary to the Lord Lieutenant of Ireland, if he can hold out any hope that in allocating the cost of non-paying lunatics in Irish lunatic asylums, the executive will, in cases where the district of

the asylum includes a county and a county of a city, so exercise the powers given it by statute as to avoid throwing on either portion of the district, exclusively of the other, the cost of non-paying lunatics who have been but a short time residing in such first-mentioned portion of the district; and whether he will consider the advisability of so exercising the aforesaid powers as to follow, between such portions of such district, the analogy of the law regulating the liability of different electoral divisions in the same union for the cost of the relief of in-door paupers.

### Unqualified "Vets."

LORD ABERDARE has carried in the House of Lords the second reading of his Bill for imposing a penalty, not exceeding £20, on any person who, without due qualifications, certified by the Royal College of Veterinary Surgeons, describes himself as a member of the veterinary profession.

### Fire in the Cambridge Anatomy School.

AN accident, which at one time caused serious alarm, occurred in the Anatomical Schools of Cambridge University last week. By the ignition of some spirit the preparation room caught fire, to which apartment, however, it was, by the exertions of the servants of the museum, and of the fire brigade, fortunately confined. No specimen of value appears to have been destroyed, though the room was much damaged.

### Bequests to Irish Charities.

MR. JOHN McCANCE has bequeathed £100 to the Belfast Royal Hospital. Mr. E. Pike has given a donation of £50 to the Hospital for Women and Children, Cork. Mr. Forster Green has given £50 to the Society for Providing Nurses for the Sick Poor, Belfast; and a similar amount has been bequeathed to this charity by Mrs. Bushell.

MR. CADGE, of Norwich, a member of the Council of the College of Surgeons, will take the chair at the annual festival of the Fellows on the evening of the election.

DR. VIVIAN POORE has been nominated to deliver the "Bradshaw" lecture at the Royal College of Physicians of London in August next.

ELIZA PATMORE, æt. 21, cook, in the employ of Messrs. Brickwell, surgeons, Sawbridgeworth, committed suicide on June 2nd by swallowing 3 oz. of aconite liniment, the largest recorded dose of this poison.

AN examination of candidates for commissions in the medical department of Her Majesty's army, will be held at the London University, on the 15th August next, and following days.

THE adjourned discussion on Dr. S. S. Alford's paper on "The Practical Treatment of Dipsomania," will take place before the British Medical Temperance Association, in the rooms of the Medical Society of London, on Friday, June 24th.

IN view of the prevalence of small-pox the Admiralty have directed a general examination of the officers and men of Her Majesty's ships at the home ports, for the purpose of ascertaining the extent to which re-vaccination may be necessary, such re-vaccination to be performed by the medical officers of the ships.

THE "Harvey Memorial" will be unveiled at Folkestone, on Saturday, August 6th. Members of the Medical Congress wishing to be present will have a special train provided for them, free of cost, by the South-Eastern Railway Co., and the Mayor of Folkestone will subsequently entertain them at a banquet.

THE National Hospital for Consumption, Ventnor, has received a legacy of £1,000, free of duty, from the late Major C. S. Barron, and one of £300, less duty, from the late Miss Martha Relfe. The Leeds General Infirmary receives £250 under the will of Mr. H. W. Eyres, and the Halifax Infirmary and Dispensary £500 by the will of Mr. James Farrar.

It seems hardly credible, says the *Liverpool Courier*, but it is a fact, that patients who resort to the dispensaries there for surgical aid, frequently steal the instruments employed in their behalf. In a case before the magistrates last week it was stated that a man who had had a wound in his head dressed, stole the doctor's scissors, and was soon afterwards found threatening to stab a woman with them in the street.

THE fiftieth anniversary of Professor Pirogoff's commencement of official life was celebrated in Moscow on the 5th instant. Addresses of congratulation were received from all parts of Russia, and from foreign countries; and deputations, said to be one hundred and thirty in number from all the Russian universities and scientific societies, either waited personally on him, or sent addresses.

It is with sincere regret that we have to record the death of Professor Rolleston, M.D., F.R.S., Linacre Professor of Anatomy and Physiology in the University of Oxford, and representative of that Corporation in the General Medical Council. Deceased was not present at the last meeting of the Council through an illness which last Thursday cut short a valuable life at the early age of fifty-two.

LAST week the Lord Mayor of London published a very telling appeal in the lay press in favour of increased contributions to the Hospital Sunday Fund, annual collections for which took place on Sunday. It is, of course, too early to give even an approximate estimate of the total collected in the various places of worship; we can only hope that his lordship's appeal will be fruitful of good results, and that last year's contribution of £31,100, which was the highest sum reached, will be this year considerably exceeded.

IN the principal foreign cities the rates of mortality, according to the latest official weekly return, were in—

Calcutta 29, Bombay 34, Paris 28; Geneva, 9; Brussels 23; Amsterdam 26, Rotterdam 17; The Hague 13; Copenhagen 24, Stockholm 26, Christiana 25; St. Petersburg 61; Berlin 25, Hamburg 26, Dresden 26, Breslau 32, Munich 37; Vienna 36; Buda-Pesth 41; Rome 28, Turin 23; New York 29, Brooklyn, 18, Philadelphia, 22, Baltimore, 18 per 1,000 of the various population.

FROM diseases of the zymotic class last week in the large towns measles showed the largest proportional fatality in Bristol, Sheffield, and Liverpool; scarlet fever in Norwich, Oldham, and Birmingham; whooping-cough in Leicester, Portsmouth, Glasgow, and Birmingham. The 17 deaths from diphtheria included 11 in London. Small-pox caused 67 more deaths in London and its outer ring of suburban districts, 2 in Liverpool, 1 in Brighton, 1 in Glasgow, and 1 in Hull; whereas no fatal case of this disease was registered in any of the other large towns.

## Scotland.

(FROM OUR NORTHERN CORRESPONDENT.)

ABERDEEN.—A YEAR IN THE LUNATIC ASYLUM.—The Annual Report of Dr. Jamieson, the medical superintendent of the Lunatic Asylum, which has been published, is a document possessing interest to the profession, and interest often of a painful nature to the public. From the statistical part of the report, we gather that the number of patients under the charge of the Institution during the past year was 717, the admissions having been 183, as compared with 182 in the preceding year, and the average number of persons resident 534, as compared with 523 in 1879. The results as to recoveries had been more favourable, the death-rate had been slightly over the usual low average of the Institution, and there had been a slight decrease in the number of parochial patients, with an increase of private patients at the lower rates. Almost all these admitted belonged to the district, only six having come from beyond it. As usual, the females preponderated, only 83 of the admissions having been males. The occupations of those admitted were of the most varied character, and not any of them apparently forming special cause for mental disorders. Sailors and fishermen formed one marked group, and farm labourers another, standing next in number to those of a larger class still—people specified as having no occupation. A large proportion of the cases at the time of admission were of an unpromising description as regarded recovery under any treatment. Of the 183 admitted, about 50 were hopeless, and 30 or more unpromising. There were 81 patients discharged during the year as recovered, their average period of residence being seven months. In half of the cases no cause could be assigned for the disorder, in about a fourth the cause is hereditary predisposition, and in the remainder undoubtedly intemperance took the lead.

THE DUNDEE ROYAL INFIRMARY.—The annual meeting of the directors of this institution was held on the 13th inst., Mr. Thomas Taylor in the chair. The report for the year stated that 1,672 patients had been admitted, being 48 fewer than last year, and that the total number of cases treated to a

termination amounted to 1,677, against 1,700 in 1880. Of these 1,452 had been relieved, 79 unrelieved, and 146 had died. There had been 80 fever cases during the year, about one-half fewer than in 1880, and there had been 14 deaths. The total of general cases was 1,597, being 53 more than in 1880. 6,957 out-door patients had been visited, and 335 had been sent to the Convalescent Home. The revenue for the year amounted to £6,257 4s. 10d., and the expenditure to £5,809 1s. 5d., leaving a surplus of £448 8s. 5d. Of legacies, £1,000 had been received from Mrs. Curr's trustees, and £3,000 from the residue of How's estate, as well as £372 from smaller legacies, and there had also been received £250 of donations. During the year £1,779 had been expended on new buildings and alterations. The chairman remarked that the report was exceedingly satisfactory, and pointed out that a great saving in the expenditure had been effected by more careful and economical management. The system of training nurses had also worked well, and from fees derived from private families there had been an increase of £61. The nurses were trained for three years, and were therefore better qualified than those whose probationary term was a much shorter tenure. The reports were approved.

**THE COMBE LECTURES.**—In continuing the course of Combe Lectures on Physiology on the 14th inst., delivered in the Training College, Edinburgh, to a large audience, Dr. Andrew Wilson dealt with the teeth and the important function they played in the preservation of health by the adequate mastication of the food. As a suitable dentrifice for their preservation he recommended camphorated chalk or magnesia. The uses of saliva and the manner of its secretion were next dealt with, the anatomical construction of the stomach described, and the manner in which food was received into it and digested explained. Speaking on pepsine, Dr. Wilson incidentally alluded to specific medicines, and remarked that so long as the British public poured medicines of which they knew nothing into frames of which they knew less, so long must the popular standard of physiological knowledge be considered low. They should take their medicine, as they took their law, from legal and authoritative sources.

**HEAVY BILL FOR MEDICAL ATTENDANCE.**—On the 15th inst. Sheriff Hallard, of Edinburgh, was engaged hearing evidence in an action for £107, at the instance of Dr. Dionysius Wielobycki of that city, against Isaac Atkinson, tailor, residing in Portobello. The amount claimed was said to be due for medical attendance on Mrs. Atkinson from 1871 to 1881; and the defence is that Atkinson did not order pursuer's attendance, and that the account is overcharged. The case had not concluded when we went to press.

**EDINBURGH—HEALTH OF THE CITY DURING MAY.**—At a meeting of the Public Health Committee of Edinburgh Town Council held on the 14th inst., the monthly report by Dr. Littlejohn, medical officer of health, was submitted. It showed that during the month of May there had been 381 deaths, giving a rate of 20·49 per annum for every 1,000 of the population. Of these, 124 were due to chest diseases, and 47 to zymotic causes, of which 24 were cases of scarlatina, 13 of whooping-cough, 1 of typhus, and 4 of typhoid fever. In the corresponding month of last year the deaths numbered 407, but the average death-rate for the month of May during the past five years has been 22·40 per 1,000. Several samples of milk had been taken and analysed, and in one-fifth of these it was suspected that there had been adulteration.

**LEITH—INCREASE OF TYPHUS FEVER.**—A short time ago

it was reported that typhus fever, which had been somewhat prevalent in Leith for some time, had been on the decrease. Since then, however, the epidemic has again increased, and at present there are in the temporary hospital in King Street ten cases, and in Leith Hospital other ten cases. Three deaths from typhus fever occurred on the 13th inst.

## Correspondence.

### THE PAY OF SANITARY OFFICERS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR.—In poor rural districts where the salary is the only income of dispensary doctors it is evident that every little emolument is more closely scanned and more highly valued than in large towns, and it would consequently appear only just and proper that the various emoluments appertaining to dispensary appointments should be equally divided.

Are they equally divided? Is it right that one man who happens to hold both the dispensary and workhouse in a town should retain the *sanitary* officer as belonging to the dispensary, and the salary of *consulting* sanitary (which is usually £30) as belonging to the workhouse? Or would it not be fairer in such a case to appoint each of the medical officers of the union consulting sanitary officer *consecutively*, each holding office one year.

To this matter I hope to be able to draw the attention of the authorities. And I trust to your justice that you will assist the less fortunate of the profession by giving the affair the prominence it deserves.

I am Sir, your obedient servant,  
VILLAGE DOCTOR.

### ROYAL COLLEGE OF SURGEONS' MEETING.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR.—There appears to me to be a misunderstanding on the part of a number of members of Council as to the wishes of the country Fellows in regard to the publication of the *procès* of their proceedings. We do not want a detailed account of every debate or trifling matter of home arrangement; a mere note of such subjects could be furnished by a member chosen as reporter, *pro tem*, at each meeting; nor would we require the division lists in such matters. But when questions of importance to the general interests of the profession arise, when the details of such a measure as the Educational Scheme, so ably elaborated by the Council, has been worked out, and the entire question brought for final decision, a short-hand writer might be employed, and a full account of the debate and the division lists should be given. The expense would not be heavy, and, I venture to say, not grudged by those who think with me. We country fellows would then, at the annual election, not only know who they vote for, but what they vote for, instead of following a blind lead as at present.

I am Sir, yours,  
JAMES MARTIN.

## Literature.

### AN ATLAS OF ILLUSTRATIONS OF PATHOLOGY. (a)

THE diseases of the kidneys, supra-renal capsules and spleen having been completely illustrated in the first and second parts of this Atlas, already reviewed in these columns, we now begin the extensive and important department of diseases of the liver. We have plates of lymphadenoma; of dilatation of the hepatic ducts in one instance from gallstones and in the other from cancer; of syphilitic cirrhosis; of red

(a) "An Atlas of Illustrations of Pathology, compiled chiefly from Original Sources, for the New Sydenham Society." Fasciculus III. Plates 11 to 16 inclusive. Pp. 8, folio. London: H. R. Lewis.

atrophy with acute yellow atrophy, with histological detail, of each; of lardaceous liver, and of the same under the iodine reaction; and, lastly, of cancer of the liver, and of the well known nutmeg liver. Appended to the Atlas is a brief but clear letter-press description of each specimen; and we have in the prefatory note a promise that the next number will conclude the subject of hepatic disease; and will contain further illustrations of morbid histology as well as a *resumé* of the present state of our knowledge of the morbid anatomy of the largest of the glandular organs. If this little treatise, so modestly styled a *resumé*, be accomplished in the same admirable manner as that on renal disease, it will be indeed valuable. We look on this Pathological Atlas, in all its three fasciculi, as one of the best things that the Society has as yet done. The illustrations are nearly life-size; the colouring is beautiful and true to nature; and we have not seen in this or any other country any work of this kind that satisfied us so much. Taken alone, it would be well worth the annual guinea; and will, when finished, constitute a treatise which every practising physician should possess.

#### THE NEW SYDENHAM SOCIETY'S LEXICON OF MEDICINE AND THE ALLIED SCIENCES. (a)

We have already reviewed the three preceding parts of this lexicon, and have hardly anything to add to the opinions which we have already expressed. The work is carefully and elaborately done; and comprehends every reference which the medical or scientific inquirer could possibly require. In fact, it is a little too diffuse; and, as with four parts it has only reached "Caffeine," we fear it will, when completed, be nearly as voluminous as the catalogue of some great university or national library. We must repeat our objection to the exceeding smallness of the type; which although our vision is excellent, is to us inconvenient. A little more care might be taken with the formulæ; for example, hydrated carbonate of bismuth is written  $2 [Bi_2 CO_3] H_2 O$  an expression which is usually and rather more correctly rendered  $2 Bi_2 O_3 CO_3, H_2 O$ . Upon the whole the work is valuable, although we think that one of a lesser size might have been more practically useful. We doubt if it be wise policy of the New Sydenham Society to issue works the coming out of which extends over a long series of years. This process has a tendency to deter new subscribers from joining—perhaps, however, judicious liberality in enabling them to make up a complete set of any current work might obviate this difficulty.

#### THE DESCRIPTIVE ATLAS OF ANATOMY. (b)

MESSRS. SMITH, ELDER, and Co., by publishing this work, have placed within the reach of students of "slender means" an accurate descriptive atlas of anatomy, in which they should have little difficulty in finding a correct representation of a part they are about to dissect. But should "subjects" be scarce, careful study of the drawings will enable them to lay in store an amount of information that will reveal itself in presence of the "body" in a more plentiful season; for, as the publishers truly remark, a thorough knowledge of anatomy can only be attained by careful and repeated dissections, combined with the study of one or more of the text-books upon the subject.

This atlas, the plates of which have been carefully revised "by a metropolitan hospital surgeon and a successful teacher of Anatomy in one of the chief London Medical Schools," will enable its possessor to economise time by dispensing with text-books having small-sized illustrations, many of which are more bewildering than otherwise.

Having spoken so far favourably of the Atlas, we think that a few of the illustrations are too darkly tinted for easy reference, particularly when the eye is assisted by artificial light only. Indeed, we had ourselves some difficulty, even with a good lens, in reading several of the names in the darker printings. But notwithstanding these limited obscurities, we do not hesitate to record our opinion that, considering the

(a) "The New Sydenham Society's Lexicon of Medicine and the Allied Sciences." By Henry Power, M.B., and Leonard Sedgwick, M.D. Fourth Part. Arteroid to Caffeine. London. 1880.

(b) "The Descriptive Atlas of Anatomy." A Representation of the Anatomy of the Human Body. In 92 royal 4to Plates, containing 550 figures. London: Smith, Elder, and Co., 15 Water-loo Place. 1880.

price at which it is offered to the professional student, there are hardly any illustrated anatomical works capable of competing with this excellent Atlas of Anatomy.

### Literary Notes and Gossip.

DR. SAMUEL CROMPTON, Consulting Physician to the Salford Royal Hospital and Dispensary, has presented a valuable collection of medical books to the committee of the Bolton Infirmary.

THE subject chosen for the Jacksonian Prize for the ensuing year is "Wounds and other Injuries of Nerves, their Symptoms, Pathology, and Treatment." For the present year it is the "Pathology and Surgical Treatment of Diseases of the Hip-joint."

SURGEON-GENERAL BILLINGS, of the United States Army Medical Department, joint author of that voluminous "Catalogue of Medical and Surgical Literature," in course of publication, and editor of the "Index Medicus," has been chosen to deliver the address on "Our Medical Literature" before the International Medical Congress in London next August.

OUR *confères*, in this country, need not fear that justice will be denied them in competing for prizes in the United States; as the Boylston prize for 300 dollars on the best dissertation "On Injuries of the Back," has just been awarded to a London surgeon, Mr. Herbert W. Page, F.R.C.S., Assistant-Surgeon to, and Lecturer on, Operative Surgery at St. Mary's Hospital.

WHILST on the subject of prize competitions, we would impress upon intending essayists, that their work must be original, and must not have been previously published in any journal or book. One gentleman, Mr. Dolan, F.R.C.S., of Halifax, a frequent contributor to our columns, has had to pay dearly for his forgetfulness of this rule, as one of the Boylston prizes "would have been awarded for his essay as the best on its subject, but that it had previously been published in the *Practitioner*."

THAT excellent little handbook, "The Edinburgh Medical School Guide," published by Messrs. E. and S. Livingstone, contains much valuable information for those intending to enter the medical profession, and especially for those proposing to study in Edinburgh. The guide contains the regulations of the University and Colleges of Physicians and Surgeons, together with full syllabuses of all the lectures and teachers in the school. Much time and money may be saved by a careful perusal of this little book.

THE Council of the Royal College of Physicians of London are to be complimented upon their choice of a recipient for this year's Baly Medal for physiological research. There can be but one opinion as to the appropriateness of the reward, and Dr. Burdon Sanderson, than whom none has done more distinguished service in the cause of physiological science, is to be congratulated upon this just recognition of his labours. That the award is popular was amply testified by the assemblage present at the Harveian oration on Saturday last, when the President of the College announced Dr. Sanderson's name.

THE proprietors of that valuable publication, *The American Journal of Obstetrics and Diseases of Women and Children*, have, we understand, completed arrangements for its simultaneous issue in London and New York. Dr. Robert Barnes—than whom a more excellent choice could scarcely have been made—is the responsible English editor, and Messrs. Baillière, Tindall, and Cox, the English publishers. The editorial and publishing arrangements in the States will remain as heretofore. Since the unfortunate collapse of the *Obstetrical Journal of Great Britain*, this large and important section of the profession has had no representative organ. The *American Journal of Obstetrics* now seeks to supply the deficiency, and starting with a subscription list of nearly 6,000, a distinguished array of contributors, editors of known ability, a journal of goodly proportions and finish, and publishers of pushing, business-like reputation, its success is assured.

We are asked by the American Neurological Association to announce that a prize of 500 dollars, to be known as the "Hammond Prize," will be awarded at the annual meeting of the Association in June, 1882, to the best essay on the "Functions of the Thalamus in Man." The conditions under which this prize is to be awarded are as follows:—1. The prize is open to competitors of all nationalities. 2. The essays are to be based upon original observations and experiments on man and the lower animals. 3. Essays are to be sent to the Secretary of the Prize Committee, Dr. E. O. Seguin, 41 West 20th Street, New York City, on or before February 1, 1882; each essay to be marked by a distinctive device or motto, and accompanied by a sealed envelope bearing the same device or motto, and containing the author's visiting card.

ALREADY there have passed from life no less than three well-known members of the medical profession, who, had they been alive, would have occupied prominent positions at the forthcoming International Medical Congress. These are Professor Sanders, of Edinburgh, in whose place, as President of the Pathological Section, Dr. Burdon Sanderson has been elected; Dr. Hudson, of Dublin, whose name is among the list of Vice-Presidents of the Congress; and Prof. Rolleston, of Oxford, who had been chosen as a Vice-President of the Section of Anatomy. Drs. Rolleston and Sanders have enriched the literature of their profession with several valuable contributions; a little book on fevers, and one or two papers to medical journals, being Dr. Hudson's only literary records.

THE following American works will be published during the next few months:— "A Manual of Obstetrics," by Dr. T. Parvin, of Indianapolis. "A Practical Treatise on Impotence, Sterility, &c., of the Male Generative Organs," by Samuel W. Gross, M.D. "Lectures on the Diseases of the Nervous System," by S. Weir Mitchell, M.D. "A Practical Treatise on Electricity," by Prof. Bartholow. Volume iii. of "Agnew's Surgery." "The Applied Anatomy of the Nervous System," by Dr. A. L. Ranney, and "Diseases of the Eye," by Dr. W. F. Mittendorf. A third edition of Beard and Rockwell's "Medical and Surgical Electricity," has just appeared.

GEOLOGICAL studies are amongst the most elevating and interesting of the many scientific "ologies" of the day, but there can be no doubt these have been greatly restricted by the very expensive appliances required for their pursuit. In Letts's "Popular Atlas," part 16, now before us, we find an admirable attempt in the right direction to popularise this branch of learning by the insertion of a geological map of the environs of London, Dublin, or Edinburgh, as the case may be, showing the varied character of the surface soil by as many as sixteen variations of colour, and when we add that there are four other excellent maps, on a large scale, of portions of India, England, and Ireland, and the price is only 1s., we think no difficulty ought to be experienced by those anxious to obtain what used to be an expensive luxury, viz., a good and cheap geological map.

THE first series of these valuable maps is now complete, and can be had bound for half-a-guinea. The size of each map is 17 by 14 inches, and the series includes:— Africa, and ditto South. America, North and South. Asia, Australia and Tasmania. Belgium and Netherlands. British Isles. Canada, Dominion of. China. Egypt. England and Wales, and ditto Geological. Europe. France. German and Austrian Empires. India and Ceylon. Ireland. Italy. New Zealand. Norway, Sweden and Denmark. Pacific Ocean. Palestine in the time of Our Saviour. Russia in Europe. Scotland. Spain and Portugal. Switzerland. Turkish Empire and Greece. United States and South-Eastern Canada. West Indies. World, in Hemispheres, and on Mercator's Projection.

NEW BOOKS AND NEW EDITIONS.—The following have been received for review since the publication of our last list, May 18:—"Student's Guide to Medical Case Taking." By F. Warner, M.D. "Students' Guide to Medical Diagnosis." By S. Fenwick, M.D. (5th Ed.) "On the Mont Doré Cure." By Horace Dobell, M.D. "Contributions to Military and State Medicine." By John Martin, Surgeon, Army Medical Department. "Practical Botany for Elementary Students."

By D. Houston. "The Scientific Roll." Vol. I. Edited by Alex. Ramsay, F.G.S. "Supplement to Ziemssen's Cyclopædia of the Practice of Medicine." Edited by G. L. Peabody, M.D. "Lectures on Diseases of the Rectum." By W. H. Van Buren, M.D. "Human and Animal Variola." By George Fleming, F.R.C.V.S. "Practical Biopathy." By E. Haughton, M.D. "The Hunterian Oration of 1881." By Luther Holden, F.R.C.S. "Treffriw and the Vale of Conway Spa." By J. W. Hayward, M.D. (3rd. Edition). "The Student's Guide to the Practice of Medicine." By M. Charteris, M.D. (3rd Edition). "Ninth Annual Report of the Local Government Board."

## Obituary.

### GEORGE ROLLESTON, M.D., F.R.S.

DEATH has been grievously busy of late among the members of the General Medical Council. Within two years have passed away—first, Sir Dominic Corrigan, next, Dr. Hudson, then, Dr. Andrew Wood, and now the representative of Oxford University. Dr. Rolleston had been so identified with the scientific progress of Oxford, had so intimately associated himself with all that has been done of late to raise the condition of medicine in this country, that to all interested in the welfare of our profession his loss must come as a severe blow. Himself an accomplished scholar, Rolleston ever insisted on the advantages accruing from a liberal education; and though he always was first to deprecate vexatious restrictions, he never failed to impress on friends and pupils, the great benefit to be obtained by bringing to medical studies a previously well and widely trained mind. His lectures at Oxford were eagerly attended; and though at the time when the writer of this notice was an undergraduate, the numbers who were engaged in biological study under Prof. Rolleston were fewer than at present, yet the labour bestowed on his work by the lecturer was invariably the most careful and painstaking. What, however, made his discourse so remarkably attractive, was the rich profusion of illustration introduced into them; and in a high degree, too, the elegant and classical delivery, inseparably associated with one who, previous to entering on a scientific career, had already obtained that highest proof of scholarly culture—a first class in the School of Literæ Humaniores. At this period, 1850, Rolleston was a member of Pembroke College, having proceeded thither from the Sheffield Collegiate School. In 1851 he was elected a fellow of Pembroke, being at the time a medical student of St. Bartholomew's Hospital. This school has much reason to be proud of, and grateful to, Rolleston, for the impetus his connection with it gave to its progress; for, undoubtedly, the large amount of favour with which Oxford men have regarded and do regard St. Bartholomew's, is chiefly due to the fact that the man, to whom of all others in Oxford they were attached, had himself done honour to the school in Smithfield. In 1854 Rolleston proceeded to the M.B. degree of Oxford, and immediately after underwent a term of active service as assistant-physician in the British Civil Hospital at Smyrna, during the Crimean war. Returning to Oxford, he was elected physician to the Radcliffe Infirmary in 1857, having the year previously added M.R.C.P. to his medical qualification. In due course, in 1857, he became M.D. Oxon., and two years later, F.R.C.P. Lond. In 1860, the re-arrangement of the science teaching staff at Oxford led to the creation of the Linacre professorship of physiology, and to this Rolleston was elected; a happy-choice, and one which did more to elevate the study of natural science at Oxford than any appointment of recent time. During his tenure of the Linacre professorship, Rolleston has influenced a large number of men who are now in the foremost ranks of the scientific worthies; and it is just to say that it has been no less the admiration exerted by his personal charm of manner than the universal recognition of his marvellous abilities that excited the enthusiasm of his pupils. To them he was, at all times, accessible, and there is probably no one of them who has not, at some time, been indebted to him for some act of disinterested kindness. We, who have again and again experienced his readiness to assist with counsel, and by the exercise of a far reaching influence, can never cease to remember with real affection, one who was—that rare combination—both teacher and friend.

In 1873 Dr. Rolleston delivered the Harveian oration at the

Royal College of Physicians, and in 1879 appeared his incomparable treatise on comparative anatomy, "The Forms of Animal Life." For some time he has been engaged on a new edition of this work, and it is to be hoped that it is so far advanced as to be available for publication. Against this, as against many of his masterly monographs—that on the prehistoric pig especially—it has been charged that the style in which they written is beyond the ordinary student. But such objectors forget that Rolleston, with all true well-wishers to medicine, placed science on a level with the highest culture, and would never admit that it could be rightly pursued save by such as were already educated in the best sense of the word. This it was that marked the man above all things else, his devotion to the supreme idea of the importance of natural knowledge, an importance which carried it outside of the pale of mere culture, and made it something to be sought for earnestly, and with the aid of all the powers that education could sharpen to be more effectual. The honours the world confer were by no means grudged to Rolleston. He was a Member of the General Medical Council, a Fellow of the Royal, Linnæan, and Zoological Societies; and at Oxford no less than three colleges, Pembroke, Christ Church, and Merton, claimed him as a foundationer. But the truest distinction of all was that which he most cherished—the love and admiration of his pupils. This was given to him in full measure indeed, and the sense of personal loss that has come with his death to all whose privilege it has been to listen to his teaching, is the best and noblest testimony to the generosity and learning of the late professor.

## NOTICES TO CORRESPONDENTS.

MR. NORMAN PORRITT.—MS. of Dr. Clarke's case received with thanks. Proof will be sent in due course.

THE PRACTICAL TREATMENT OF DIPSO MANIA.—The discussion on Mr. Alford's paper, which appeared in our issue for June 8th, will be resumed at the Medical Society of London on Friday afternoon next at 4 o'clock. Members of the profession, whether or not members of the Medical Temperance Association, are invited to take part in the discussion.

DR. BUZZARD.—Continuation of Clinical Lecture received too late for insertion in present number; proofs will be sent you in time for next.

STUDENTS' NUMBERS.—Although we are frequently at variance with opinions expressed in the lay press on matters medical, it nevertheless gives us pleasure to admit that one of its most respectable organs, *Public Opinion*, is correct on the present occasion. At page 792 of that publication for Saturday last the Editor, replying to a correspondent, says: "Each September the *Lancet*, *Medical Times*, *British Medical Journal*, and *Medical Press and Circular* publish a students' number, all of which are good; we are inclined to recommend the arrangement of the last named." In thanking the Editor of *Public Opinion* for his favourable criticism, he will be glad to learn that his judgment is confirmed by a large section of the community, our last "Students' Number" having been long since out of print.

### THE COMING INTERNATIONAL MEDICAL CONGRESS.

The following two letters were received by the Honorary Secretary, Mr. Wm. MacCormac, F.R.C.S., in acknowledgment of notices of the Congress and programmes sent to the Empress of Germany and the King of Italy:—

Berlin, March 26th, 1881.

I had great pleasure in receiving your communication of the 14th of March, and have taken a lively interest in its contents, as well as in those of the programme of the International Medical Congress which is to meet in London during August next. I have much pleasure in informing you that on account of the great importance of your deliberations, I have commissioned Sanitäts-Rath Prof. Dr. Kuster, Principal Surgeon of the Augusta Hospital in Berlin, which is under my patronage, to attend the Congress. I, at the same time, express my desire that during his stay in London you will aid him in all matters which may concern his important mission, or the interests of the above-mentioned Hospital. I conclude with the sincere desire that this international meeting of medical authorities on English soil, the birth-place of so many important discoveries for the alleviation of human suffering, may contribute to scientific progress, and prove an enduring bond of union between nations in the cause of humanity.

(Signed) AUGUSTA.

Rome,  
Office of the King's Private Secretary,  
May 29th, 1881.

THE King, my august Sovereign, has received the programme of the International Medical Congress which will take place in London in August next. His Majesty much appreciates this attention, and recognises the importance the Congress possesses for the interests of science and humanity.

Moreover, the courteous and polite expressions with which you accompany your offering have been warmly appreciated by the King, who desires me to render to you his most cordial acknowledgments. His Majesty most sincerely desires that the work may be fruitful in the best results, and will be happy to see Italy compete with other nations in the study of medicine.

In intimating to you these gracious sentiments of my Sovereign, I am glad to profit by the occasion to assure you of my distinguished esteem and respect.

THE MINISTER OF THE KING'S HOUSEHOLD.

The following lines to the memory of the late Dr. Peete, of Dublin, composed by a learned judge, and set to music by Sir Robert Prescott Stewart, were produced for the first time at the last meeting of the Hibernian Catch Club:—

THAT voice is hushed, the tuneful tongue is still,  
Whose music oft thrilled through this hallowed fane,  
That hand now cold, whose touch, with healing skill,  
Was prompt to soothe the sufferer's bed of pain.  
Mid squalid homes, Death claimed thee for his prey,  
Helping the helpless, thou thy life hast given,  
One place is vacant in our midst to-day;  
Our voices falter—thine is heard in Heaven.  
Yes, we believe, Physician, Minstrel, Friend,  
Those tones are heard amid th' angelic throng,  
That voice and form, remembered to the end,  
Too soon departed, live in praise and song—  
And strains, which here below our souls have riven,  
Now swell the glorious symphonies of Heaven.

J. A. L.

MR. H. Y. SAINTON will find the subject exhaustively treated in the last edition of "Aitken's Science and Practice of Medicine."

F. R. C. S.—Not now, he has withdrawn from the candidature.

MR. G. K. COOK.—Our Publisher informs us that the number is out of print. You can refer to it at the office, or in the library of the College of Surgeons.

MR. B. ROBERTS.—MS. not yet to hand, we cannot say.

DR. J. O. F.—Sorry we cannot oblige you, the puff is too pronounced.

MR. WHATFORD (Brighton).—The cases are decidedly interesting; space shall be given them as early as convenient.

DR. T. M. D. will please receive our best thanks.

PHYSICIST will find his question answered in our "Literary Notes and Gossip" column.

MR. E. A. B.—You have begun at the wrong end.

FRAUDULENT PAREGORIC.—At the Hyde Police Court John Wild was summoned for selling paregoric which the certificate of the Cheshire County Analyst showed to have been adulterated with 25 per cent of water. Mr. Wild said he did not make the paregoric; he merely sold it as he got it and the traveller gave him his word that it was pure. The Magistrate's Clerk: You should get that in writing. Mr. Wild: Ah! it's too late now; it's like locking the stable when the horse has gone. If I'm sent for here again it will not be paregoric that will bring me. (Laughter.) A fine of 5s. and costs was imposed.

## VACANCIES.

Ashton-under-Lyne District Infirmary.—House Surgeon. Salary commencing at £80, with board. Applications to the Hon. Sec. before June 25.

Bolton Infirmary.—House Surgeon. Salary commencing at £120, with board. Applications to the Hon. Sec. by June 24.

Boyle Union.—Medical Officer. Salary, £120, and £10 as Medical Officer of Health. Election, June 27.

Farringdon Union.—Medical Officer for the Shrivensham District. Salary, £70, with extra fees. Applications to the Clerk by June 22.

Liverpool Northern Hospital.—Assistant House Surgeon. Salary, £70, with board. Applications to the Chairman of Committee by June 24.

Luton Union.—Medical Officer for the Barton District. Salary, £75, with extra fees. Applications to the Clerk by June 27.

Salford.—Resident Medical Officer to the Wilton Fever Hospital. Salary, £150. Applications, endorsed "Resident Medical Officer," to be sent in by June 30.

St. Bartholomew's Hospital, London.—Two Casualty Physicians. Applications, with testimonials, to be left at the Clerk's Office before July 8.

St. Peter's Hospital for Stone, London. Assistant Surgeon on the Staff. Applications to the Secretary before July 1. (See Adv.)

## APPOINTMENTS.

COOKE, E. M., M.B., M.R.C.S.E., Medical Superintendent of the County and City of Worcester Lunatic Asylum, Powick.

COOPER, W., M.R.C.S.E., House Surgeon to the Croxdon Hospital.

DEANE, E., L.F.P.S.G., Medical Officer to the Second District of the Shepton Mallet Union.

FOSTER, N. S., M.D., C.M., Medical Officer to the Stoke Lyne District of the Bicester Union.

GAMGER, J. S., F.R.S. Ed., M.R.C.S.E., Consulting Surgeon to the Queen's Hospital, Birmingham.

HILLIARD, H. C., M.D., L.R.C.P.L., M.R.C.S.E., Medical Officer to the Caterham District of the Godstone Union.

HOPK, E. W., M.B., B.S.C., L.R.C.P.L., Resident Medical Officer to the Netherfield Fever Hospital, Liverpool.

## Births.

SAGER.—June 14, at the County Asylum, Melton, Suffolk, the wife of Wilson Sager, Medical Superintendent, of a son.

WICKERS.—June 15, at Upper Tollington Park, London, the wife of Henry A. Wickers, L.R.C.P.Lond., of a daughter.

## Deaths.

JONES.—June 15, at his residence, Sydenham Park, S.E., Edward Jones, M.D., aged 66.

MATTHEWS.—June 3, at his residence, The Acacias, Dovercourt, Arthur Matthews, M.R.C.S.E., aged 75.

MURDOCH.—June 13, at 106 Pembroke Road, Dublin, Sidney Murdoch, M.D.

NUTTALL.—May 21, in San Francisco, California, Robert Kennedy Nuttall, M.D., F.R.C.S., youngest son of the late Colonel J. C. Nuttall, J.P., of Tittour, co. Wicklow, aged 66.

### A COURSE OF LECTURES

#### ON THE LAWS OF INHERITANCE IN RELATION TO DISEASE.

Delivered at the Royal College of Surgeons of England, June, 1881.

By Prof. JONATHAN HUTCHINSON, F.R.C.S.,

Senior Surgeon to the London Hospital; and President of the Pathological Society of London, &c.

#### LECTURE II.

DR. JOSEPH ADAMS, in a work on hereditary disease, drew a distinction between inheritance and family prevalence, which, though of questionable importance, may be found serviceable in considering those instances of maladies which, apparently not transmitted from generation to generation, yet exhibit a remarkable tendency to occur in the members of a single family. Dr. Adams conjectured that congenital disease was not hereditary, and that confusion had been introduced into the discussion of such diseases as were strictly inherited, and such as occurred with single family prevalence. So firmly convinced was he of the truth of his supposition, that he would place no restrictions upon the marriage of persons in whom there was nothing to indicate inherited weakness, according to his definitions. In support of his theory he quoted Haller, to the effect that transmission of diseases does not invariably occur, a fact noted also by Sir Henry Holland. Against these, however, we must oppose that the existence of atavism was unsuspected, and that the histories of the cases did not extend sufficiently far back to warrant the conclusions drawn. In fact, Sir Henry Holland's explanation, that the diseases considered under the head of non-inherited ones, were to be ascribed to derangements of the nervous system, shows the common misappreciation at that time of the real causes at work.

Family prevalence is to be regarded in the light of an intensification, rather than an origination, of disease. Ichthyosis, for instance, is rarely found in a family which has not some record of hereditary tendency to the condition; and full consideration of all the circumstances connected with the phenomena presented by one family prevalence, necessitated the conclusion that the factors supplied by prepotency and atavism were adequate to afford explanation of them. The lecturer's views on this subject had undergone modification as a consequence of his observations; and particularly the fact, that inquiries as to family histories of affected persons rarely extended beyond one, or at most two, generations, inclined him to regard one family prevalence as an intensification of a tendency aided by favouring circumstances. The deaf and dumb schools at Old Trafford, Manchester, yielded evidence in support of this opinion. At this institution, inquiries made respecting the family history of over 100 children—deaf mutes—elicited accounts of members of the respective families afflicted in the past, in but a very few instances. The records, however, rarely extended beyond a single antecedent generation, and their value is hardly worth considering.

Hereditary transmission of deficiencies, arising from suppression of parts, is of very rare occurrence, a fact commented on by Dr. Adams, who declared that malformations due to suppression were not inherited. Examples of such deformities are occasionally met with, the more usual forms being the absence of one or more fingers, of the radius or ulna, &c. A case was recorded in which a hand malformed in this direction had been transmitted from father to son, but in the same family several members had been born with club-foot, and there was in it a tendency to malformations of the extremities; and speaking generally, these defects are rarely repeated in descendants of the affected individuals, while examples, even, of suppression of digits are of very unusual occurrence.

Some defects—hare-lip, for instance—appear to be sporadic and accidental, and often are associated with other imperfections in the same family. Histories of hare-lip occurring in many members of the same family are not uncommon, and one exceptional case, in which, out of

a family numbering twenty members, ten were so affected, had come under Mr. Hutchinson's own notice. Neuro-muscular malformations, e.g., club-foot, are but seldom accompanied by family histories of the defects; but, according to Dr. Little, the congenital club-foot is hereditary, he having operated on three generations in direct descent for the same variety of the deformity; and, further, he believes that it is only rarely that the heredity is not traceable. Whether the loss of balance between opposing sets of muscles in these cases is of nervous origin or not, is impossible to say. Similar deformities of the hand are rare; but in the eye, interference with the power of the levator superioris results in ptosis, which is decidedly capable of transmission, and affords, too, in the congenital form, a remarkably good example of the effects which may follow on a disturbance of function of even a weak muscle. Slight symmetrical ptosis is frequently met with in females whose systems are wanting in tone; but, as a rule, it is not characterised especially by one family prevalence, though a case of the kind is recorded where three children in the same family were affected by ptosis.

Coloboma iris is often hereditary, and may prevail in several members of the same family in a mild form, agreeing in all in the degree of injury set up. The size of the cleft, however, may vary much in different children of the same family.

Animals and men are not rarely born with superfluous structures, such as supernumerary digits on one or both limbs, &c., and the condition in which these additional parts exist may vary within very wide limits. With them there may be *webbing* of the extremity; the extra finger may be pedunculated or sessile, thick or thin, long or short; in fact, it may be almost indefinitely peculiar. These structures are invariably associated with the history of similar growths in the ancestors of the person exhibiting them; and there are generally two or more members affected in a family. One family prevalence in connection with them is not uncommon, and it is recorded of a family of six females that they all refused to marry, lest by so doing they should perpetuate a deformity of this kind born with them. This class of malformations acquires high importance from their relation to the theory of atavism, which receives the strongest confirmation through them. Neither sex is especially affected by tendency to over-growth, nor does either enjoy a special immunity from it. The facts of inheritance requiring special explanation, become clear in their connection with these occurrences, when considered under the light shed on them by the laws of prepotency. Thus descendants from a parent stock endowed with supernumerary digits, in the third generation may develop the redundant structures without either the parents or grandparents having exhibited it, reverting, in fact, to the great great grand-parent type.

The strength of the tendency, moreover, would appear to be increased by atavic inheritance; but in cases of marked one-family prevalence, the probability of inter-marriages helping to explain the phenomena is deserving of consideration. Such a case, for instance, is cited by Dr. Stirling, in which the subject of digital malformation had two children similarly affected, one of which had likewise two descendants, and in the third generation there were two children who inherited the deformity. In the sixth volume of the "Ophthalmological Reports," Mr. James Higson published the account of a woman suffering from malformation of the lens, whose daughter suffered likewise. In 1874 these same patients came under Mr. Hutchinson's notice at Moorfields, and with them other members of the family in another generation. These all presented for treatment on account of the same defect of the lens, and thus afforded a history of direct transmission of an inherited disease through four generations. In these families those subjects of the defect who were girls were the eldest born, but they had not then inherited it from the female parent. In all the

cases the eye was, in other respects, sound and strong, and there had been no convulsions or other illness during childhood. These instances show that disease consisting in malformation of the lens is easily transmissible, and there seems good reason to believe that congenital occurrence of the condition is associated with family tendency to ophthalmic disease. Malformation due to disease in the eye set up during intra-uterine life, was referred to by Sir Wm. Wilde, who in 1862 published an account of the knowledge then current concerning these deformities, and to which even now there is scarcely anything to be added that is new.

*Albinism* affords many interesting examples of hereditary transmission of structural defects, the condition being always congenital, and being but little modified subsequently. The degree in which it occurs varies a good deal, but, as a rule, pigment is absent altogether, and hence the name. It exhibits no preference for either race or sex, but in some cases it may occur in exaggerated forms. It less frequently prevails among many members of the same family than does ichthyosis, but it is with little doubt hereditary, although Sachs, himself an albino, and with a sister similarly affected, could not trace hereditary transmission to himself. Possibly, there may be some unknown, or hitherto undiscovered, individual in his family from whom it has been derived, as in the case of an albino born by a negress, whose alarm at the occurrence was appeased by her husband's explanation to the effect that the same thing was of frequent occurrence in his family. It is curious, however, that in this case the result was a perfect albino. There are no intermediate stages between this and the dark parents; and we find, too, that albinism is more common, as is leucoderma, among dark, than among fair people. In the lower animals the condition is certainly transmitted; nothing, however, is positively known as to its causation, except that it is more complete among darker races. There is an account of two French families, indeed, entirely unrelated, who, residing in the same cottage in the country, subsequently possessed albinos among their members; but this affords no explanation of the fact. It is a common observance, however, that special colour of hair and eyes are transmitted, but this affords nothing to account for the *mode* of transmission. Prof. Osborn, of Dublin, has published the account of a family marked by the possession of a tortoise-shell eye, all the descendants of which were born with the same peculiarity.

*Pangenesis* affords an explanation of the facts, supported by observation, and noted by Dr. Joseph Adams, that conditions of excesses are more easily transmitted than those of deficiency. The doctrine of Pangenesis originally enunciated by Herbert Spencer, has been elaborated and elucidated by Darwin, in whose hands it has been made to serve the explanation of the most difficult problem of heredity. It shows clearly how the new organism may arise from the composite seed made up of contributions from every structure of the parent, and, through the *geminules* derived from them, sufficing to reproduce them in every particular.

This conception is the most daring, perhaps, ever essayed by man, and it assuredly affords the most feasible explanation of growth yet offered. The union of ovum and sperm cell is at once followed by mutual assistance and opposition among the *geminules* constituting them. We may liken the process to the mixing by a farmer of all the seeds gathered from many meadows in various stages of perfection and growth, which he sows, and the multifarious characters of the resulting crop from which might be taken to resemble the consequences following the hereditary transmission of forms and peculiarity, &c.

Since the existence of defects implies the loss of those *geminules* derived from the parts extinguished, there can be no perpetuation of the character, and thus atavism is here at fault.

## CLINICAL LECTURE

## ON THE DIFFERENTIAL DIAGNOSIS BETWEEN CERTAIN HYSTERICAL CONDITIONS AND MYELITIS.

*Delivered at the National Hospital for the Paralysed and Epileptic.*

By THOMAS BUZZARD, M.D., F.R.C.P.

*(Continued from page 505.)*

ABOUT a year ago I admitted a young woman on account of paralysis in all four limbs. She was described by those who sought admission for her as a case of hysterical paralysis. Seven months before she came here the patient had complained of pain in her back, side, and head. The pain was very bad on the vertex. Next she became very weak on her legs, and moved them in an incoordinate manner. At this time there was great weakness of the right hand, and the right side of the face was paralysed. Soon she became unable to walk at all.

A month after she had begun to be ill this patient had a fit, and this had been repeated on five or six occasions before her admission. I have little doubt that it was the occurrence of these fits, associated, as they were, with paralytic symptoms, confined at first to the lower extremities, which gave rise to the diagnosis of hysteria in this instance. The apparent want of connection between the two symptoms would be suggestive (unless the possible existence of multiple lesion were insisted upon) of the inconsistencies of certain forms of hysteria.

When we came to examine this patient with the ophthalmoscope (which we never omit doing), it was found that she had optic neuritis. This fact, of course, immediately carried us a long way on to a diagnosis of serious brain lesion. Moreover, in addition to this, she had a bedsore, and the presence of this alone was significative of organic disease.

Let me call your attention to the note respecting the state of the muscles of this patient's legs on admission. "Lower limbs powerless; not the slightest power of movement; no wasting, no rigidity. No difference between the two limbs. The muscles respond to faradaic currents of somewhat higher strength than is required normally." (As the case advanced there was much wasting, and the legs were rigidly drawn up.) I shall have occasion to refer to the question of wasting of muscles and its diagnostic value. For my present purpose it is only necessary to add that this patient grew worse and worse, that in spite of the most diligent attention her bedsores extended, and that she died some months after admission. The autopsy showed basilar meningitis and spinal meningo-myelitis, the cord being disorganised and softened throughout. The patient, it should be said, was the subject of inherited syphilis.

One feature of this case was of especially great importance. As a rule, the pain in the back, which is associated with spinal meningitis, is chiefly felt when the patient turns from one side to the other. But, in this instance, if the patient's account is to be accepted, the description of pain was exceptional. The following note was taken on her admission:—"On inquiry it seems that throughout her illness she had suffered from pains in the back, that would come on suddenly, and leave her whilst she walked about the room. At no time during her illness has she had pains in her back, which were made worse by sitting up, or by movement." Now it is possible that the inflammation of the membranes of the cord occurred as a sequel of the myelitis, and had not begun when the note was taken. I do not know that this was so, but simply suggest the possibility. It is well to remember the point, because, in the case described, I can well understand that the character of the pain was very liable to mislead as to its nature. It would divert the attention from the idea of meningitis. Whilst upon this point I will refer to another case, which may be conveniently contrasted with the last.

In 1872, a married lady, *et. 26*, was sent to me by a medical man in the country, on account of loss of use of both lower extremities. She had been married three years, and had two children, the youngest being six weeks old. In early life her back had been "weak," and she was made to lie down a good deal. Her health had generally been very good. There was a history of gout in the family.

The following note was taken:—"Fourteen months ago, after getting very wet in a ride, she was seized with rigors,

and went to bed. A few days afterwards she began to have pain in the lower part of the dorsal region of the spine, and this spread all over her arms and legs. She was not confined to bed. Off and on, ever since then, she has had these pains about her. There has not been any swelling of her joints.

Her mother told me that in June last she was complaining exceedingly of her back—always the lower part of the dorsal region. At that time there was nothing wrong with her legs. She had, at times, paroxysms of flying pains about her head, face, and arms. The pains were always most severe at changes of weather. She has never, she says, gone a fortnight, or even a week, without pains since she was attacked fourteen months ago.

Three months ago these pains were especially bad, and it was then that her legs began to feel weak. There was nothing wrong with the sensibility. A month later she would be liable to be attacked with great pain from her hips to the feet, accompanied by sudden loss of power, so that she was obliged to lay hold of something. At this time she was approaching her confinement, and one morning, within a month of it, she lost power to such an extent that she had to crawl upstairs on her hands and knees, and three days afterwards became completely powerless in her legs. At this time she could not lie on the left side on account of pressure of the gravid uterus.

Nine days after her confinement, her toes, she says, became perfectly dead numbed, and she could feel nothing with them, not even pinching. At this time she could just slide her feet about, but could not lift them.

When I saw her she lay in bed, and averred that she was unable to move her legs at all. She could move some of her toes a little. Ticking the soles produced no reflex action. There appeared to be almost absolute loss of sensation in the legs: but on inquiry, she said that she was aware of the position of her feet. She had never had any feeling of waist constriction. She could not raise her body in the least without using her arms.

On examination there was tenderness on pressing upon the spines of the dorsal vertebræ from the fifth downwards. There was nothing wrong with the arms, bladder, or bowels, and no tendency to bed-sores. The legs looked thin, but there were no signs of muscular atrophy. I applied electrical tests. There was a little delay in getting the muscles to contract by induced currents, but after application for a few minutes of strong currents, they reacted to a much lower power, to a strength, indeed, which did not at first influence them. The reaction to interrupted voltaism appeared normal. The induced currents were employed vigorously for about five minutes. At first she could not feel them, but after a minute or two she complained of their making her feel ill. The muscles of the legs generally were well exercised by the currents. Five days afterwards I saw her again. The power of movement had much improved. She could lift either foot from the couch, and could dorsal flex them. I noted now that elaborate and prolonged tickling was felt merely as touch on either sole, although she stated that she was naturally very ticklish. I now faradised all the muscles of the lower extremities energetically. The process gave her evident pain, and there was a great deal of voluntary movement. Two days afterwards she walked across the room, supported by two persons. Faradism was again applied very freely and sharply. Another two days past, and the patient was able to walk downstairs by herself. She returned home a day or two afterwards quite recovered, and has had no recurrence of the paralysis. In this case the exposure to wet and cold, followed by rigors, suggested spinal meningitis, and made the diagnosis somewhat doubtful at first. Where there is a history of injury, the same kind of doubt may easily arise.

Three or four years ago I saw Mrs. B., a young married lady, *et. 22* (one child), who had just come from abroad. A year previously she had slipped and fallen down twenty-five steps striking her spine between the middle and lower part. She is said to have been unconscious for ten minutes. She then got up, as she told me, and felt a tingling and pricking in her legs. She walked upstairs, dressed, went out to dinner, and that night slept quite well. Next morning she found herself unable to move her legs, and had not the least feeling in them. She was in great pain in the back and outer part of her thighs. For forty-eight hours she was powerless in her legs. Then they were rubbed and she recovered power, though whether completely or not she

does not know. But she could move her legs about to new postures.

For three months she was kept to her bed, except on one occasion, five weeks after her fall, when she was allowed to get up. But she had so much menorrhagia that she took to her bed again. Whilst lying there she lost muscular sense downwards from the waist. Had no idea of the position of her body from the waist downwards, but if she were touched she could feel perfectly well. During the time she lay in bed the catheter had to be employed on one occasion only, otherwise she never suffered from any difficulty with the bladder or the bowels. Nor has there been any feeling of waist constriction. At the end of three months she got about again, and was soon able to walk two miles without fatigue. Six months after the accident she gave birth to an infant which she nursed perfectly well, and was in excellent health for two months. After this, from time to time, always after fatigue, she got pain in the back where she had been hurt. On the voyage to England she had been quite well, except a little of this pain, until a week before I saw her. She had been up all one night with her baby, who was fretful, walking up and down, and carrying it in her arms. This brought on great pain in her back and pain all down the legs. She lay down all day, and it seemed to pass off. Next day she found her legs would not go where she wanted them to go. They kept crossing one another. This was on a Sunday. She went to church, but coming out found she could not command her legs. Two hours later, when trying to rise from her chair, she found she could not move. She was carried upstairs. She could not feel a touch, or pinching, or hot applications. She was very cold in her body, as well as in her legs. There was no starting of the limbs.

I found, on examination, that there was no irregularity in the spinal column, but she complained of tenderness when the 11th and 12th spines were touched. The faradaic excitability of the anterior tibial muscles was normal. Her general health seemed good, but she was of a nervous temperament, and of somewhat delicate constitution. It was said, indeed, that for three years at an earlier period she had suffered from disease of the hip-joint, but I had no means of verifying this. She was advised to lie in bed, and in a few days all pain had gone, and she felt quite well.

A few weeks later she was at the seaside and swam one day for half-an-hour out to sea, besides going through much fatigue with picnics and walking. For some time she remained perfectly well. Then, after unusual fatigue, she got a return of menorrhagia, but still persisted in going about and swimming, till one day she "collapsed." Then her feet and hands became icy cold, and for hours it was impossible to warm her. At first she could not walk. She did not lose sensation in her legs, nor control of the bladder. In a day or two she succeeded in walking again, but could not co-ordinate her legs, and was unable to go up or down stairs. She soon recovered, and when I saw her a month later there was nothing the matter with her legs. She then complained of difficulty with her breath occurring just before menstruation. She had, whilst talking, a hysterical gasping respiration. I have since lost sight of this patient.

A case which first came under my notice in March, 1879, has proved to present such difficulties in diagnosis that I think it may be mentioned with advantage.

Miss ———, æt. 16, was seen by me in consultation on account of loss of power in the left leg. It seems that she was well until the previous July when, in walking, she began to trip with the left leg. This gradually increased so that she had come to walk with difficulty. She told me her leg would not move properly, it dragged and did not bend. She sometimes caught the foot and fell.

She had not suffered any pain. There had never been anything wrong with the left arm. She began to menstruate between 12 and 13 years of age. The catamenia had always been natural and regular. She is naturally, her mother describes, very nervous, and she laughs a good deal. She is not now depressed in spirits. In walking I observed that the movement was a good deal like that of a limb asleep. The leg was swung round in an arc, the knee not being bent, and the point of the foot being dropped. She had no power, she said, to dorsal flex the foot.

On examination I found the legs well nourished. The skin was cold, and there were chilblains on the left foot. There was nothing wrong with the function of the bladder or

legs I found the patellar tendon reflex greatly in excess. In both, but especially in the left, there was well-marked foot clonus. In neither was there any reflex action on tickling the sole. The faradaic excitability of the muscles was normal.

It is only, so she told me, since her illness—*i. e.*, since she began to trip in walking, that she has ceased to be ticklish in the soles of the feet. She used to be very ticklish. Before she lost power she used to complain of tenderness in the spinal column. When she bent her head down she felt that something was dragging her back. Sometimes she felt this on going to bed at night, at others in getting up in the morning. It was not constant, and was a sort of aching. Twice it has happened to her when in a warm room to feel giddy, and as if there were a weight in her head, and then she could not walk at all. Her mother told me that since this began, *i. e.*, about eight or nine months, she had never on one single occasion walked properly, and that she had remained exactly as I saw her for two months. At the commencement she complained that her leg trembled, and the knee fell backwards. Percussion on the spinal column gives no sign of tenderness.

There has never been anything wrong with the bladder or rectum, and she has never complained of waist constriction. Her medical attendant some months since found some tenderness about the tenth dorsal vertebra, for which he blistered her.

I prescribed for her, and she was afterwards taken to two distinguished consultants, who both thought the case one of hysteria. I heard, a twelvemonth later, that she had not improved in her walking, and that her medical adviser (who was not visiting her) sometimes saw her about his neighbourhood clinging to the arm of an attendant and hobbling along.

In March last (a year after my first examination) I again saw her in consultation with a colleague. At this time, whilst the right calf measured 12½ inches, the left was only 11½. With the left leg she could not feel quite so well as with the other. A purple discolouration was noted on both legs near the ankle. The feet were cold, and there were chilblains.

On applying induced currents, we found that the excitability was slightly lessened in the tibialis anticus of the left leg as compared with that on the right side. Examination of the spinal column showed a slightly abrupt change of level (as though from the prominence or sinking of a vertebra) at the lower part of the dorsal region. Below the level of this there was a decline of cutaneous sensibility.

We recommended that a Sayre's jacket should be applied. This was done. I have since heard that she is somewhat improved.

This case may easily be of an hysterical character, and if it be so, it furnishes a good illustration of my remark that you cannot cure a case of hysteria so long as you have any serious doubts as to its nature. The girl has been ill 3 years. If the condition be one of hysteria she will be cured suddenly some day, probably by a bone-setter, and my eminent colleagues, as well as myself, will be covered with ignominy!

Such symptoms as this girl presents might be caused by slow compression of the spinal cord in the dorsal region. One would have expected, however, that a cause of compression sufficient to produce the very considerable loss of power seen here would, in accordance with Brown-Séguard's observation, have been attended with considerable anaesthesia of the opposite limb. The anaesthesia, such as it is, occupying the same side as the motor paralysis, is suspicious, though not of itself conclusive. Suspicious also is the slight lowering of electrical excitability in the muscles on the front leg; but I did not have the opportunity of testing this, as I should have done, on some other occasion. The exaggerated reflex and foot clonus are, as I have already pointed out, quite consistent with the case being purely of an hysterical character. It is, I think, very important to remember this. The only thing remaining is the slight anatomical peculiarity described. You will find all sorts of peculiarities in the spinal columns of healthy people if you look for them. I should not, therefore, count much upon that alone, but when associated as it is with symptoms which may be due to slow compression of the cord one is bound to allow the possibility of some Pott's disease of the vertebrae lying at the bottom of the case. It was for that reason that we recommended Sayre's jacket. I should add that the absence of sole reflex in the circumstances points strongly in the direction of hysteria.

(To be continued.)

## THE PRESENT STATE OF THE SEWAGE QUESTION. (a)

By Prof. W. H. CORFIELD, M.A., M.D., Oxon., F.R.C.P. Lond.,

Professor of Hygiene and Public Health in University College; Examiner for the Sanitary Science Certificate, University of Cambridge.

AFTER some introductory remarks on the importance of removal of refuse matters and the results of their non-removal as shown by the spread of black death, oriental plague, cholera, and enteric fever, the entire depopulation of many ancient cities being doubtless due to such causes, and after pointing out that utilisation, though no doubt important, was a secondary matter, and, indeed, what an athlete would call "a very bad second," the reader of the paper proceeded to consider the systems of sewage removal and treatment at present in use under the two heads of Conservancy Systems and Water Carriage.

In the former the refuse matters were either collected unmixed with anything else, or mixed with ashes, earth, &c. The first of these plans was now being adopted in several large towns, as Birmingham, Rochdale, &c., and it might be said to be the only successful one among the conservancy systems, it is certainly the only one from which a profit has been obtained; the manure in all other plans is nearly valueless, and the results obtained by the Sewage Committee of the British Association show that the earth compost after having been used in the cloest six times is only as rich as good garden soil, and will not bear the cost of carriage.

After a summary of the results obtained by the conservancy systems in which they were shown not to be solutions of the questions, especially as they leave the liquid sewage still to be treated, but in which it was admitted that under certain circumstances, as where it was necessary to reduce the bulk of the sewage, they might, with proper precautions, be adopted, the water carriage system was considered somewhat in detail; its advantages in the continuous removal of refuse from houses pointed out its advantages, shown not to be inherent in the system, but to be mistakes made in carrying it out; as for instance, sewers pervious to water, or too large, or not ventilated, or without sufficient fall, or with a blocked outlet, or discharging into rivers, house-draining not properly disconnected, the folly of turning surface waters, and, in many instances, even springs and streams into sewers, and so increasing the difficulty of dealing with the sewage at the outfall was insisted on. The various chemical processes for the treatment of sewage were passed in review, and all shown to be quite inadequate to cope with the difficulty, though some might be useful as preliminary aids to purification.

Filtration through soil and wide irrigation were next treated of at some length, and the results obtained by them described. Certainly the sewage had been satisfactorily purified in many cases, the conditions for satisfactory purification in winter being that the sewage pass through the soil, and not merely over it. Crops of all kinds had been grown by means of it, and in soil that would otherwise bear nothing; and the British Association's Sewage Committee had shown that as great a percentage of the manurial constituents had been utilised as was, on an average, utilised of the best commercial manure. Although, for various reasons, it had seldom been found to be remunerative, the reader adhered to his opinion, formulated ten years ago, that sewage irrigation would ultimately be remunerative in many instances, and that opinion was abated by the committee appointed by the Local Government Board in 1876 to inquire into modes of treating town sewage. An irrigation farm should be supplemented by a filter-bed to receive and purify sewage when it is not wanted on the farm. The supposed dangers from the proximity of such farms, or from the spread of entozoic disease, were found to be purely imaginary; it was, on the whole, a better solution of the question for a large number of places than any other, and if, as was very likely, we had a series of dry years, its adoption would receive a great impulse. Where towns cannot make sewage utilisation pay, they must be content to be taxed, to a slight extent, to get rid of a most serious nuisance, and to secure a low death-rate.

(a) Abstract of a Paper read before the Sanitary Institute of Great Britain, Tuesday, June 21st, Dr. Alfred Carpenter in the chair.

## Clinical Records.

NORTH-EASTERN HOSPITAL FOR CHILDREN,  
HACKNEY ROAD.

*A Case of Acute Tonsillitis.*

Under the care of Dr. C. E. ARMAND SEMPLE.

E. H., *æt.* 11½, came as an out-patient on May 18th, having had severe sore throat and difficulty in swallowing for four days. The child was evidently much distressed, and complained of great pain on the right side of the neck when any attempt at swallowing was made. The face was flushed, the skin all over the body very hot; pulse very full (120); tongue brown; breath very foul; severe headache; bowels constipated. She had taken nothing but liquids for three days.

*Throat on Examination.*—The soft palate and pillars of fauces are tense and markedly congested—the right side far more so than the left, where the soft palate is pushed forward by the corresponding tonsil. The right tonsil is greatly enlarged, extending beyond the mesial line. On the anterior surface are two small yellow points, almost coalescing. The whole tonsil is very tense and globular. The uvula is also much swollen, and is, as it were, "glued" to the right tonsil; glands beneath right lower jaw much enlarged.

As the breathing of the child was distressing, and the pain great, it was decided to puncture the tonsil, and this was done with a sharp-pointed bistoury, and quite a drachm of thick, yellow pus was let out. There was no immediate marked relief, but the child was placed in a special ward, in a *steam tent*, and the following mixture was ordered—

℞ Tinct. guaiaci ammoniati, ℥ss.;  
Mucilag. tragacanthæ, ℥j.;  
Aqua, ad, ℥ss. t. d. s.

Port wine, 4 oz., milk, beef-tea.

This was at 4 p.m., and by midnight the child was sleeping quietly. The breathing was somewhat harsh, but not in the least distressing.

May 19th.—The throat on examination this morning shows the right tonsil much decreased in size; still discharging pus; this discharge continued until May 22nd, but the inhalation of steam, the treatment by guaiacum, and the above diet were kept up until the 25th, or for one week from admission.

The other tonsil did not become affected, as is frequently the case, and the patient went out well on June 5th.

During the last week in the hospital she was ordered—

℞ Potass chlorat., gr. x.;  
Tinct. ferri. perchl. mx.;  
Aqua, ℥j. b. d.

No fomentations or poultices were applied to the throat. There was no history of any previous attack.

## Huddersfield Infirmary.

*Otorrhœa—Stoppage of Discharge—Hyperpyrexia, which subsided after Ejection of Small Quantity of Pus from the Ear.*

Under the care of Dr. CLARKE, F.R.C.S.

Reported by Mr. NORMAN PORRITT, House Surgeon.

On the morning of the 29th May, William Henry Salter, weaver, married, *æt.* 28, presented himself in the Casualty-room of the hospital. He complained of pain in the right side of the head, radiating from the right ear, and stated that for eight years there had been a running from this ear. Twelve days ago the discharge stopped, and his symptoms and distress (for which he consulted without benefit a prescribing chemist), culminated in the condition in which he was found.

He was quite rational, but had an anxious restless look, at times alternating with one of stupidity. The skin was cool, pulse 92—regular, temperature in the axilla 102.8. The signs in the chest were negative, there had been no diarrhoea, and the physical examination of the abdomen revealed nothing abnormal. The pain was most intense at a point a little above and behind the right ear. He had vomited once before leaving home, but never previously, and there was some (but not distressing) vertigo. On examining the ear the bottom of the meatus was found strewn with a layer of old secretion, and the surface of the membrane could not be seen. There was no sign of redness, and he showed no sign of tenderness

during the time the speculum of the auroscope was within the meatus. Nor was there externally over the mastoid process or adjacent parts any swelling or redness, nor tenderness on percussion, but the lymphatic glands at the anterior border of the right sterno-mastoid were enlarged. Close to the patient the unpleasant odour of old necrosed bone was faintly perceptible. When put to bed, he told us that ten years ago he fell from the top of a bus, alighting on his head, and remained unconscious several hours. He pointed out a scar along the posterior border of the right lower jaw, which he said was produced at the time. However, he was able to work two days afterwards. He continued well for two years, when what appears to have been an abscess formed near the angle of the right lower jaw, and in a week or two afterwards a running commenced from the ear of the same side. He can assign no cause for the abscess, and he had had no previous pain. The running has continued ever since, and he "always felt better when there was free discharge."

He has always enjoyed good health, and never had much headache. Three or four years ago he began to grow deaf, and has become much worse lately. He had measles and scarlatina when young, and recovered well, no running from the ears supervening. There are no signs of syphilis.

The right temple was shaved, and after the ear had been syringed without bringing away more than what appeared to be a few epithelial scales, poultices were applied. Seven grains of calomel were at once given, and followed in three hours by two ounces of black draught.

In the evening his temperature rose to 105°. The pulse rising to 102. He was quite rational, but complained much of the pain, which was "just same as marbles running all over his head," and now most severe over the position of the sub-occipital fossa. The ear was again syringed with negative result. Half a drachm of bromide of potassium with fifteen grains of chloral hydrate were given.

May 27th.—The bowels have been well moved, and he slept well after the draught. Temp. has fallen to 97.8, and he expresses himself as feeling much relieved. At 12 noon, the temperature had risen to 100.4, and at 2 p.m., to 106—when a consultation was held.

The patient himself, beyond appearing somewhat stupefied, being otherwise unaffected. It was then decided to trephine the mastoid process, as the history and symptoms pointed to the probability of pus lodging in them or the tympanum, although the absence of the usual signs of inflammation did not support this view of the case.

Ether was selected as the anæsthetic, but was not taken well by the patient, and during the struggling and coughing which the first three or four respirations caused, about three fluid drachms of sticky and extremely offensive pus were ejected with considerable force from the ear. The diagnosis was thus unexpectedly confirmed, and after the ear had been syringed with weak Condy's fluid, the man was put to bed when his temperature fell as follows:—

May 27th, 3.15 p.m.—103.2°.  
4.15 p.m.—102.4°.  
5.30 p.m.—100°.  
6.40 p.m.—99°.  
12 midnight.—99.2°.

28th, 6 a.m.—99°.

8 a.m.—97.4°.

7 p.m.—98.4°.

29th, morning.—97.2°.

Evening.—97.6°.

30th, morning.—98°.

Patient dismissed, with astringent carbolised lotion to syringe the ear daily.

June 5th.—After syringing, he lay down with the diseased ear undermost, and about a cupful of badly-smelling matter ran out of the ear. After this he felt very sick.

8th.—Is well, discharge from the ear continues. There was no facial paralysis, nor numbness in the face, nor any symptoms due to interference with the functions of cranial nerves.

*Remarks by Dr. Clarke.*—The absence of internal redness and tumefaction is unusual in these cases, and the result of the struggling during the attempt to breathe the ether suggests the possibility that forcible inflation of the tympanum, either through the Eustachian catheter, or by the pneumatic bags of Valsalva, or Politzer, might be found of value in cases of retained otorrhœal discharge.

### ON PARACENTESIS THORACIS BY ASPIRATION IN ACUTE PLEURISY.

Par Dr. GEORGES DIEULAFOY,

Professeur Agrégé à la Faculté de Médecine de Paris; Médecin des Hôpitaux; Lauréat de l'Institut (prix Montyon).

Translated by C. A. OWENS, M.D., L.R.C.P. Ed., L.R.C.S.I., &c.

(Continued from page 532.)

#### CHAPTER II.

##### *Accidents following Paracentesis Thoracis.*

HAVING discussed and detailed the indications for performing the operation of paracentesis, let us now consider the chapter of objections. When the effusion is sufficiently considerable to menace the patient's life, every one recognises the necessity for operating, although even then it is still put off till urgency is more pronounced and asphyxia is imminent; want of accordance steps in when effusions of medium intensity have to be dealt with; and if medical men can be found who do not hesitate to puncture the chest for an effusion of two pints, there are others who reject the operation formally, once and for all. It is rejected as an operation which urgency alone will justify, although experience shows that certain pleurisies, in spite of repeated vesications, take entire months to be absorbed, possibly becoming chronic or purulent, although it is known that the formation of cardiac and pulmonary clots will be much more likely to result from the displaced heart and flattened lung, which will be also much more exposed to become fixed in their new positions (false membranes) the longer they have been compressed by the fluid. It is not denied that the damage thus done to the aëration and circulation of the blood is very prejudicial to the patient; and yet, in the face of these considerations, it is acknowledged preferable to run the hazard of an effusion, which will be badly absorbed, than to encounter accidents which have occasionally accompanied puncture of the chest, so much are these accidents feared. Doubtless the discussions and publications of late years have largely tended to render hesitating or timid those whose convictions were not firmly rooted. The goal has been passed, and, nevertheless, those conscientious observers who have reported the unsuccessful cases cannot be thanked too much, for the more a danger is known the better is it avoided. Congestion and pulmonary œdema, albuminous expectoration, slow or rapid asphyxia, syncope, hemiplegia, apoplexy, more or less sudden death, &c., are the accidents which have been noted as following paracentesis; and these I now proceed to examine and discuss, ascribing to each its just value.

Pulmonary œdema and congestion, albuminous expectoration, asphyxia. The lesions of the respiratory function, which I will now describe, may be classed in a primary group. They occur as follows:—

A quarter or half-an-hour after the completion of the operation of paracentesis the patient is seized with cough and oppression of breathing, expectoration frothy, and sanguineous or albuminous; on auscultation fine sub-crepitan râles of pulmonary œdema are heard, sometimes mingled with blowing sounds and cœgophony, these last symptoms possibly persisting after the evacuation of the fluid; then, by degrees, the cough ceases, respiration is re-established, and in an hour the mischief is at an end, the patient now only showing benefit from the operation. In other cases the symptoms are more serious. The cough is spasmodic, there is increased anxiety, and the patient coughs up 1½ ounces (Woillez), 7½ ounces (Vulpian), 2 pints (Desnos), and as much as 2½ pints (Moutard-Martin) of expectoration, which forms layers in the vessel—the upper, foamy and yellowish; the lower, denser and albuminous. The intensity and duration of the dyspnoea, and the quantity of expectoration are variable; and generally half a day, or a day elapses before a return to the normal state. Finally, in some cases, fortunately very exceptional ones (I am only aware of six), these accidents prove fatal, the asphyxia following the operation declaring itself so rapidly and with such intensity that the patients were carried off in ten minutes (Girard), a quarter-of-an-hour (Gambault), in a

few minutes (Legendre), very rapidly (Dumontpallier), in four hours (Béhier and Lionville), and in two hours (Bouveret).

Besides these, other fatal accidents occur, but they form part of a series of cases which I shall classify in another group, and to the nature of which I shall recur further on. At present I confine myself to an examination of cases in which the operation was complicated with accidents from dyspnoea, with œdema and pulmonary congestion, for the most part accompanied by albuminous expectoration. These misfortunes had been noted by Dr. Pinault already in 1853; later they were observed by Drs. Epine, Woillez, and Marotte; since then they have been discussed at the Academy of Medicine, and at the Medical Society of Hospitals, and have been fully gone into by Drs. Terrillon, Foucart, Mercier, and Lereboullet. Whenever this question has been broached, the discussion has naturally borne upon the origin and nature of these casualties. A patient on whom paracentesis has just been performed is seized with cough and oppression of breathing, the mouth is filled with froth and foam, and the sputa are albuminous. Whence do these complications spring?

Can we attribute them to a wound of the lung done while operating? No, because the primary vacuum renders such a puncture impossible; however, a post-mortem examination has never revealed a wound of the lung, and supposing a wound of this organ had allowed the pleural fluid to enter the bronchi, it would at the same time have permitted air from the bronchi to enter the cavity of the pleura during the fits of coughing, and symptoms of hydropneumothorax would have been manifested, and which has never happened. Therefore we can no more accuse a puncture of the lung while operating of this accident than we can its spontaneous perforation. But what is responsible is the acute œdema of the lung, and the rapid pulmonary congestion, which in their turn cause albuminous expectoration and asphyxia.

This is the theory which has been cleverly defended by Dr. Hérard—a theory we now uphold, and which I believe to be absolutely correct. Under the influence of congestion and acute œdema, the serous and albuminous parts of the blood exude into the alveoli and bronchi; the sub-crepitant râles heard during life, and the pulmonary œdema found after death, demonstrate clearly the nature of the lesion. If the serous exudation is moderate in quantity, and the congestion is not very intense, the symptoms of dyspnoea need not be dreaded, as the patient escapes with frothy expectoration of albuminous fluid, of which the duration and intensity are variable. But if these phenomena are more marked, if the lung is invaded by œdema, and the bronchi and trachea are embarrassed by fluid, asphyxia becomes imminent, and death may supervene suddenly. At the same time, albuminous expectoration is not always a constant symptom. It was wanting in two cases where there was a fatal termination; and it is even asked whether this absence of expectoration (pulmonary œdema being present) is not rather an unfavourable symptom.

The cause of this rapid congestion and acute œdema remains for explanation. If physiology be consulted, it is seen that section of the pneumogastric nerves is generally followed by "the presence of frothy exudation in the bronchi, and sanguineous engorgement of the pulmonary tissue" (Cl. Bernard), this congestion and œdema being, doubtless, due to the paralysis of vessels. As far as we are concerned, the mechanism of this, as explained by physiology, matters little. The well-observed fact remains that following certain operations of paracentesis thoracis, pulmonary congestion, and acute œdema of the lungs, with or without albuminous expectoration, are known to occur. Why is this?

(To be continued.)

THE committee of the International Medical and Sanitary Exhibition are sparing no pains to promote the success of this exhibition, and judging from the admirable plans which have been issued to exhibitors, the collection of medical and sanitary appliances to be opened at South Kensington on July 16th, will be of national importance.

## Special.

### GOVERNMENTAL INQUIRIES INTO THE CAUSES OF RECENT OUTBREAKS OF FEVER.

#### "Typhoid Fever" in Haverfordwest.

HAVERFORDWEST has a population estimated at 6,662, composed chiefly of classes usually resident in the country and market town of an agricultural district. In 1871 and 1872 an outbreak of typhoid fever, causing 7 deaths, occurred in the borough; *little light* was thrown upon its causes. In the winter of 1874-5 another outbreak of the same disease took place during the winter season. In 1879-80 7 cases of fever were recorded in the western district of Haverfordwest. Four cases occurred at Albert Town, a suburb of the town consisting of small overcrowded cottages without drainage. The subject of the first case had come home ill from a place in the rural district; the others had probably visited at his house when he was ill. One case occurred in the lower part of the town. Of the cases in Albert Town 2 were fatal; the last which occurred recovered about February or March, and from that time, as far as could be learned, it remained free from fever during six months. In August several cases of typhoid fever occurred in different parts of the town, in widely separated localities, in some instances unconnected with town sewers or water supply, without apparent direct communication among each other, or common cause. Sanitary defects existed in the localities infected; but so also did they at others not infected. The reporter is unable to account for means by which the specific poison of the disease may have been introduced, or how these patients came, at the same time, to be exposed to it. There is no evidence that fever was introduced by persons indicated in the report. But when the fever began the weather was hot and dry; the rainfall during the 12 preceding months  $2\frac{1}{2}$  inches less than in any corresponding period during the preceding 32 years. For the cottage in which the first case occurred, water, for a time, was obtained from wells, or purchased at the door. The watercart supposed to have been filled from a stream which received sewage from houses and privies; inmates of other houses, however, drank water from the same stream, and yet had no fever. This contradictory evidence being noticed, the report says:—"It is more probable that the cases owed their origin to a common and widespread cause in operation at an earlier date, such as the contamination of the town sewers or water service by infectious matters from some previous case, the nature of which escaped recognition, or which was not reported." Up to the middle of December there occurred 88 cases; the number of households attacked were 60. Of the 88 cases 20 were in female servants; these being, as a class, mostly exposed to exhalations from sink and water-closets, and most in the habit of using water as a beverage. In the succeeding paragraph, however, the statement occurs that "it is not possible to say in what way typhoid fever came to be in Haverfordwest." There can be no doubt that the various insanitary conditions existing in the town have conduced to the spreading of the disease, but how much of the result may be attributable to each of those conditions, there are no means of ascertaining.

#### "Typhoid Fever" in the Totness Urban and Rural Sanitary Districts.

The estimated population of Totness as given is 35,557; of the remaining portion of its sanitary district, 17,027, equal to a total of 52,584. During the years from 1876 to 1880, both inclusive, the recorded deaths by fever were respectively 8, 9, 6, 10, and 13; by diarrhoea, 4, 4, 7, 6, and 10. In 1876 there occurred 3 by measles, and 7 by scarlet fever; in 1877, none by the former, but 3 by the latter affection. In 1878 none by either; in 1879, as in 1876, there were 3 by measles, 7 by scarlet fever; in 1880 the numbers were 2 and 3 respectively. The only other epidemic disease noted was whooping, namely, 1 case in 1876; none in 1877, but in the three succeeding years, 9, 2, and 10 respectively. With regard to typhoid fever, although there had been some scattered cases, mostly of doubtful nature, yet the majority of fatal cases occurred in distinct groups, and particular localities. With few exceptions, the scattered cases have either a history of probable or possible importation, or the fever has probably not been of a specific infectious nature. The grouped cases were assumed to have been all cases of enteric or typhoid fever,

for although in some of them the cause of death was *certified* as *typhus*, the difference appeared to be one of nomenclature, determined by the appearance of the *skin*, and amount of *abdominal* symptoms, rather than one of nature. Cases occurred in close connection at the same time in the same family, some being called *typhus*, others *typhoid*. In other instance of so-called typhus, the nature of the sequelæ, namely, *hæmorrhage* from the bowels, pointed to typhoid rather than to typhus.

Adverting to certain places named as belonging to the same district, the following represents the purport of remarks made, namely:—

a. *Haberton*.—Altogether 21 cases set down as of *fever* occurred between June, 1877, and February, 1878; of that number, 6 died, namely, 3 by *typhus*, 3 from *typhoid*. Eight households were affected. Except three cottages by the brook, all received their water supply from *different* sources, and their drainage went in *different* directions. The reporter is unable to say that any evidence shows that the disease was distributed by the agency of milk supply. At East Leigh, a hamlet of Haberton, there have been a *few* cases of fever at *various* times. No history of introduction was made out, but *nuisances* exist in the vicinity of cottages where the *fever* occurred; a well, from which *some* of the inhabitants used to get their drinking water was condemned by the county analyst; it has been closed.

b. *Ugborough*.—Twenty-two cases of *fever*, with six deaths between February and August, 1879. It is *suspected* that sewage percolated into the water reservoir; when opened some *black slime* was found oozing from the face of the rock, and to this contamination the outbreak of fever was attributed. The reporter, while *not prepared* to deny the *possibility* of this explanation, indicates, as a difficulty, the *partial* distribution of the water. No history of infection could be ascertained. With regard to cases in Modbury Street, it *seems probable* that percolation from the privy *may have* reached the well, and that the use of contaminated water *may have* conveyed the disease to other houses. It *seems likely* that that *effluvia* from *specifically* infected sewers *may have helped* to spread the disease. In a yard behind the Ship Inn, described as low, ill-paved, and filthy, cases occurred in *summer*.

c. *South Brent*.—*Typhoid* fever has not been absent any year since 1875. *About* 30 cases in 19 households. This village occupies a high and open site; many cottages, old and dilapidated, inhabitants employed, some in agriculture, others at a flock manufactory. The water supply from a reservoir fed by a hill side spring. Out of six back-to-back houses, fever occurred in *two* about the same time. In an alley near them is an untrapped grating, *believed* to lead to a drain. The window of a kitchen opened into a slaughter-house; immediately under the windows of the public meeting room, a huge heap of pig's dung was piled. But these circumstances do *not* bear directly upon the question of fever production.

d. *Galmpton*.—An outbreak of *enteric* fever here in the *summer* of 1881; its special incidence upon shipwrights in a boat building yard. The cottages, superior, some new; water, spring, and good; village clean; sewage runs into the brook, its bed excavated, to form catchpits, for sediment to be used as manure. Formerly a tidal pond, containing large quantities of sewage and river mud, emitted offensive effluvia, but these *unheeded* by persons accustomed to them. On the margin of this pond, a spring or well, its water formerly used for drinking. It *does not* appear that the tide had reached that well while fever was prevalent; but it is *probable* that the spring *may have* become contaminated by *percolation* from the stream above. A farmer was the first person attacked. He *may have* contracted the disease at Totnes, though *no history* of infection was ascertained. Late in *May* several cases occurred among *workmen* in the yard nearest the tidal pond, and among inmates of *adjacent* houses; the total cases till *August* about 30. Of these *some* 14 shipwrights in that yard, 8 children near the pond, 1 a shipwright in another yard, but who would have to pass the pond on his way to and from work, 2 in persons not employed near the pond, but who were in the habit of going there, and 6 in members of families previously attacked. It thus appears that the cause of fever existed locally, but whether in effluvia from *specifically* infected sewage mud, or from drinking sewage polluted water, or both combined, the reporter was *unable* to say.

d. *Buckfastleigh*.—Population considerably over 2,638, a busy manufacturing village. In the *summer* of 1880 a group of cases of fever, 21 in all, with 8 deaths, occurred at Buck-

fast, an outlying hamlet. *No history* of infection traced in regard to the first case of the series; the house in which its subject resided, like others of the group, was new, well-built, and well-drained, but at the *lowest* part of the village. The fever prevailed in *dry* weather. All the persons attacked had been in the habit of getting water from a pump well near a dairy and general shop. The inhabitants of houses at the *upper* part of the hamlet, who drank water from a well, but escaped with one exception. The water used at the dairy was always soiled, and no fever appeared in the household. The cause of the outbreak is *obscure*, but circumstances *appear* to point to the water of the pump-well as having *probably* been concerned in it. In 1875 an epidemic of scarlet fever occurred in the village, the deaths thereby, 27. The origin of the disease was *uncertain*. Since that date a good deal of improvement has been effected in the "sanitary condition" of Buckfastleigh.

### THE "MEDICAL PRESS" ANALYTICAL REPORTS ON THE PRINCIPAL BOTTLED WATERS.

By CHARLES C. R. TICHBORNE, LL.D., F.C.S., F.I.C.,

President of the Pharmaceutical Society of Ireland, Lecturer on Chemistry, Carmichael College of Medicine, &c.

WITH

### NOTES ON THEIR THERAPEUTICAL USES.

By PROSSER JAMES, M.D., M.R.C.P.Lond.,

Lecturer on Materia Medica and Therapeutics at the London Hospital, Physician to the Hospital for Diseases of the Throat, &c.

(Continued from page 535.)

SELTZER—continued.

WE have already referred to the difference in the composition shown by the analysis published by us, and those previously given. We subjoin a copy of Kastner's analysis, and the discrepancies pointed out will be readily perceived.

*Seltzer according to Kastner.*

Bicarbonate of soda	...	...	...	9.7741
Chloride of sodium	...	...	...	17.2285
Chloride of potassium	...	...	...	0.2390
Sulphate of soda	...	...	...	0.2615
Phosphate of lime	...	...	...	0.0004
Phosphate of alumina	...	...	...	0.0002
Phosphate of soda	...	...	...	0.2615
Fluoride of calcium	...	...	...	0.0016
Bicarbonate of lime	...	...	...	2.6678
Bicarbonate of magnesia	...	...	...	2.5586
Bicarbonate of protoxide of iron	...	...	...	0.1088
Bicarbonate of manganese	...	...	...	0.0032
Bromide of sodium	...	...	...	0.0002
Silica	...	...	...	0.2500

33.4054 grs.

The most important discrepancy here is the non-appearance of any soluble salt of magnesium except the carbonate. This is decidedly wrong as applied to the bottled waters, as evidenced by the fact that, on the evaporation of the seltzer water to dryness in a capsule, and on re-solution in water and filtering, the greater part of the magnesia is found in the filtrate; had it existed entirely as carbonate, it would have been all left in the insoluble form on the filter. The larger portion of the magnesia is evidently present as chloride, and this fact

accounts for the pleasant, sweet taste which the seltzer water possesses. The chloride of sodium adds to this a piquant flavour which is very grateful. It is not generally known that the magnesium bitter taste is peculiar to sulphate of magnesium. It is that salt which has induced the name, "bitter wasser," to be applied to so many of the Continental purgative waters. The bitterness may be perceived in a solution of carbonate of magnesia in carbonic acid gas, or in a few of the other salts in a more or less degree, but not so in the chloride of magnesium.

The discrepancy observed in the analysis may be accounted for by a remark made by Messrs. Ingram and Boyle, the well-known mineral water importers. They say, "that the water as it flows from the spring contains a small quantity of iron, and when bottled in glass bottles, is liable to discolour wine or brandy when mixed with it." (From the tannic acid present in the wine forming tannate of iron.) "This disadvantage, which applies not only to seltzer, but all waters of a chalybeate character, is obviated when the water is bottled in earthen jars, as a small quantity of common salt is placed in the jar, which causes the iron to deposit. The omission of this precaution, or carelessness in performing it, which sometimes occurs, explains the misapprehension."

We cannot see that it explains anything, except the fact that the amount of the chlorides, as compared with the original spring, is largely increased. Nor can we see what difference the bottling in stoneware as compared with glass, has to say to the precipitation of this iron without some of the lime or other salts in the imperfectly glazed bottles act upon the water, and cause a precipitation. If such were the case it would be a very strong argument for discarding the earthen bottles. We are rather inclined to think that the real object in using these bottles is to hide any deposit which might fall, and which would look ugly in the glass bottles.

In describing the Vichy waters, we dwelt at some length upon the bottling of the waters, and as the seltzer waters represent a typical system of bottling in which stoneware jars are used, we will devote a small space to the description of the bottling process as carried on at Nieder Selters, premising that the account is chiefly taken from an amusing book which, as regards its scientific and other information, is rather out of date—i.e., "Bubbles from the Brunns of Nassau." The profitable spring, which was the property of the Duke of Nassau, was placed at the disposal of the people after a certain number of hours had been spent in bottling for stock. The earthen bottles or jars are supplied from various manufacturers, and are therefore uncertain as regards their quality. A number of young girls carry thirty-four of them at a time on their heads to an immense trough, which is kept constantly full by a large fountain-pipe of clear fresh water. The bottles on arriving were here filled brimful (as the writer conceived), for the purpose of washing, and were then ranged in ranks of a hundred each, there being ten rows of seventy bottles. Next morning the writer perceived that about one-third of these bottles were in a mutilated state, their noses lying by their side supported by the adjoining bottles. What could possibly have been the cause of the fatal disaster which in one

single night had so dreadfully disfigured them, I am, says the writer, totally at a loss to imagine. On asking for an explanation, he was informed that, being supplied from different manufacturers, they are, after filling brimful, left for the night. The officer visits them next morning—whose wand of office is a thin, long-handled little hammer—when he walks along each line, and the instant he sees a bottle not brimful, without listening to any long-winded argument, he at once decides that there shall be no mistake, and thus at one tap or blow of the hammer off goes the head. The bottle must either contain a crack, be porous, or it will retain the water twelve hours at its original level. After this performance the men reverse the full bottles in the ranks, every broken bottle being thrown away. By this means the bottles undergo a process of washing after soaking for twelve hours, and to a certain extent this remedies the objections which we are now about to raise to the stone bottle.

Every one knows that even in well-glazed stone or earthenware bottles there is a certain amount of porosity. Now not only does this allow the gas to get in, but soluble constituents of the clay are rendered up to the water. Ems, Pullna, and other waters, are still put into these old-fashioned stone bottles, and we think it is quite time the practice were discontinued in favour of glass bottles. As the bottles are made of the roughest material, the vessel would be most objectionable were it not for the method provided at Selters of soaking them. However, this is not infallible, as is proved by a bottle before the writer now, which, although still retaining the original cork, and being perfectly free from any crack, has lost half its contents after standing for six months in an upright position.

## Transactions of Societies.

### THE MEDICAL TEMPERANCE ASSOCIATION.

THE adjourned discussion on Dr. Alford's paper on "The Practical Treatment of Dipsomania," which appeared in our issue of June 8th, was resumed at the Medical Society of London on Friday last. Dr. RICHARDSON, M.D., F.R.S., occupied the Chair.

The debate was reopened by Dr. JAMES EDMUNDS, who stated the propositions before the meeting; first, that a relapse into drunkenness was a disease, the disease of inebriety, and was allied to such nervous complaints as insanity, hay-fever, or sick-headache; secondly, that the attack might be suddenly induced by such climatic conditions as sea-air, east-wind, dryness of the atmosphere, extremes of heat or cold; in fact, by anything disturbing the harmony of the organisation. Loss of property, bereavement, physical injury, sun-stroke and railway accident, were also cited as exciting causes which might be responsible for a bout of drunkenness; thirdly, that legislative power for the control of such inebriates in asylums was the necessary remedy; fourthly, that such asylums should be founded by public subscription, and fifthly, that by such means, valuable lives would be restored to their families. Dr. Edmunds went on to say that in support of these propositions, no reliable statistics, or even well-defined cases, had been quoted, whilst on the other hand, one such asylum, founded on public subscription, had already failed. If they were not to repeat such a failure, it was necessary to understand distinctly what was proposed to be done. He then narrated the circumstances of a number of cases of dipsomania, that had come directly under his own experience, which pointed to conclusions quite at variance with every one of the foregoing propositions. This accumulated experience of cases of people in all ranks and positions of society, who relapsed

into habits of drunkenness, compelled him to say that it was not disease, but rather a vice, a mere indulgence of the animal passion for drink. Drunkenness was one of those things which would always be evolved, firstly, according to the character of the individual, and secondly, according to the circumstances in which he was placed with regard to early temptations to drink. Men had various resisting powers against the temptations to steal, to lie, and to indulge in various sensual passions; thus he submitted that they had this resisting power, which varied in every individual, and the temptations by which the individual was surrounded, and that out of that they would get more or less of drunkenness. To admit for a moment that a bout of drunkenness was to be excused because the wind had blown from the east, or because a man had had a whiff of sea-air, had been hot or cold, and such like excuses, reduced the matter to an absurdity, and stultified the whole of their machinery for the repression of crime. Coming to the practical treatment of cases of dipsomania, the speaker said that it turned upon total and unconditional abstinence from intoxicating drinks, and from all substitutes, such as laudanum and chloral. If debilitated, they must lie in bed, and abstain from exposure to cold, and from work, until their strength re-accumulated. If unable to digest ordinary food, they must live upon oatmeal gruel and milk, and broth, or barley-meal, and vegetable foods. If they could not sleep, they must suffer the horrors of one, two, or three restless nights, but take no narcotics. Then they would sleep, and sleep soundly, and at the end of a week they would be well. All other treatment was unnecessary and delusive. There were two classes of these patients; one able to pay, and one not able to pay. Those able to pay would be best cared for in the private asylums to which many eminent medical men were already devoting their time and their capital, and which ought to be supported. Those unable to pay, instead of being committed to prison over and over again, for periods of a few days, ought to be committed to a reformatory institution, somewhat like a lunatic asylum, in which these people should be detained at the expense of the country for 3, 6, 9, or twelve months, according to discretion, and their previous history.

Dr. RIDGE followed, and generally concurred with the opinions expressed by Dr. Edmunds. The power of self-control was distinctly enfeebled by the action of alcohol, and those people who imbibed it were more the creatures of impulse than when they did not indulge in it. He believed that the craving which people felt for alcoholic drinks in so-called moderation was only the small beginning of that almost irrepressible craving which people who were called dipsomaniacs experienced; it was simply a matter of degree. As regarded the practical treatment of dipsomaniacs, there was no doubt, he thought, that the sooner they could be cut off from alcohol, in any form, the better; it was distinctly for their advantage that they should not be allowed to get it. They should seek first to restore tone and power to the nerve centres enfeebled by alcohol, and time and good food would effect that to a large extent. He thought that caffeine would be most conducive to the restoration of the mental powers, it was a true stimulant; whereas alcohol was indirectly a stimulant, but really a narcotic. Dr. Ridge then read two or three letters received from gentlemen residing in India, tending to show that vegetarians are less liable than flesh-eating people to the insidious action of alcohol.

Dr. STEWART, of Clifton, thought, as scientific men they ought to be careful of the use of any term which implied their adherence to a theory which they were not prepared to stand by. They had heard that day that the theory could not be in its entirety maintained that the disease which was called dipsomania was a disease which had any right to be allied to mania at all. Others admitted that it was a disease; but it was very doubtful if they could put it under the category of a disease which was usually spoken of as mania. It was important that they should not affix a term of this kind to a condition of things which they wished the public to view in its proper light. "Drink-craving" was a word with which he thoroughly agreed, and it did not involve any theory that would lead to any misunderstanding whatever. Dr. Stewart then proceeded to give as his illustrations some cases of dipsomania which he had treated; and substantially concurred with Dr. Edmunds on the vital point that if they were to successfully treat persons under this unfortunate "drink-craving," the first step to be taken was to remove all stimulants from them. One reason why he had been successful in treating dipsomania was that he did not "preach to his patients." Vegetarianism, he did not believe was suited for this

climata, and as regarded the circumstance that the Brahmins of India were singularly free from drunkenness, he could only say that it was possible that it found its true reason in the religion of the people which entirely doomed all those who indulged in alcohol.

Dr. DOWSE also addressed the meeting, and, generally speaking, demurred to the arguments of his predecessors. He believed that the majority of drink diseases, in the absolute sense of the word, were really and truly dipsomaniac. In most of the cases he had seen, he had found that there was a marked transmission of the disease in their system.

Dr. G. B. CLARK, M.D., of Fenwick, West Dulwich, was not quite decided upon one side or the other, but all the evidence that he had seen went to show that the craving for drink was not a hereditary disease. If it was a disease, what was the proper remedy for it. There had been all sorts of moral influences suggested not generally considered to be within the province of the physician, but more supposed to be in the field of the clergyman. He did not see why those who used a mixed diet should drink more than those who subsisted entirely on a vegetable diet—there was probably a little more water in vegetable food than in animal food, but it was scarcely an argument. In Bengal or Bombay they did not see much drunkenness; but amongst the vegetarians of Madras they would find almost as great drunkenness as amongst Europeans. Dr. Clark, after pointing out that in the case of dipsomania, tonics such as nux vomica, plenty of healthy excitement, and similar restoratives, were about the best media, concluded by going to the root of the question, and saying that prevention was better than cure. Take away the public houses—that were a standing temptation to the working classes—and if they wish to have legislative interference on the subject, he thought it ought to be in the direction of local option.

On the motion of Dr. NORMAN KEER, the debate was adjourned till that day fortnight.

#### ODONTOLOGICAL SOCIETY OF GREAT BRITAIN.

MONDAY, JUNE 13TH.

MR. THOS. ARNOLD ROGERS, President, in the Chair.

MR. DAVID HEPBURN read a paper on

CHRONIC SUPPURATION CONNECTED WITH THE TEETH.

After briefly referring to the most common form, that of ordinary alveolar abscess, in which a fistulous opening existed on the surface of the gum communicating by a short canal with the root of a tooth, Mr. Hepburn proceeded to describe those more complicated cases in which the pus had penetrated to a part remote from the original source of the mischief. Of this he related several instances which had come under his own observation, as where an impacted wisdom tooth had given rise to a large abscess which opened in the neck. In most cases the extraction of the tooth which had been the original cause of the mischief would be followed by the closure of the sinuses; but it was not always easy to discover which tooth was the cause of the mischief, and sometimes when this had been extracted little improvement would result. This was generally due to the presence of some small portion of necrosed bone, but this again was often most difficult to discover, and might remain for months keeping up irritation. Mr. Hepburn related several cases illustrating these points. In one the patient was under treatment for five months, and was eventually cured by the extraction of an upper lateral incisor. In another the patient had been suffering for seven months from a profuse discharge of offensive pus coming from the socket of an extracted lateral. Active treatment was persisted in for eight months, when suspicion fell upon the central incisors; these were extracted, and at the bottom of the socket of the right central a piece of dead bone was found and a canal which communicated in a circuitous manner with the sinus which had been so long discharging; immediate improvement followed. Mr. Hepburn spoke highly of the value of eucalyptus oil in these cases; it was a powerful antiseptic and a useful stimulant, and was altogether far preferable to carbolic acid for this purpose. Tincture of iodine was also useful, but the great point was to find out and remove the cause of the irritation as soon as possible.

An interesting discussion followed.

REGISTERED FOR TRANSMISSION ABROAD.

THE  
MEDICAL PRESS AND CIRCULAR

Is published every Wednesday morning. Price 5d. Post free, 5½d.

POST FREE TO ANNUAL SUBSCRIBERS . . . . £1 2 6

„ IF PAID IN ADVANCE . . . . . 1 1 0

\* Post-office Orders and Cheques to be drawn in favour of—

A. A. TINDALL, 20 King William Street, Strand, London, W.C.

A. H. JACOB, 3 Molesworth Street, Dublin.

Agents for Scotland:—

MACLAUGHLAN and STEWART, South Bridge, Edinburgh.

A. and W. STENHOUSE, Hillhead, Glasgow.

SUBSCRIPTIONS FOR FRANCE are received by Messrs. BAILLIÈRE, Rue Hautefeuille, Paris—post free in advance, £1 2s. 6d. per annum.

SUBSCRIPTIONS FOR THE UNITED STATES are received in New York, by Messrs. WILLMER and ROGERS; Philadelphia, by Dr. BRINTON; post free in advance, 5½ dollars (£1 2s. 6d. per annum; or direct from the Offices in this country for the same amount, if remitted by International Post-office Order

ADVERTISEMENT SCALE.—Whole Page, £5 0s. 0d. Half Page, £2 10s. 0d.; Quarter Page, £1 5s. 0d.; One-eighth Page, 12s. 6d.

Small Announcements of Practices, Assistances, Vacancies, Books, &c., of Seven lines or under, 4s. per insertion; 6d. per line beyond. Considerable reductions are made from the foregoing Scale when orders are given for a series of insertions. Letters in this department should be addressed to the Publishers.

“SALUS POPULI SUPREMA LEX.

WEDNESDAY, JUNE 29, 1881.

THE HOSPITAL HOME SYSTEM.

THE introduction by St. Thomas's Hospital of the system by which the legitimate revenue of a charitable institution is augmented through contributions by paying patients, has, we must assume, been in some degree successful. At any rate the authorities at Guy's Hospital are—presumably emboldened by a knowledge of that which has followed from their whilom neighbour's proceedings—about to invite patients willing to pay for trained service, to avail themselves of the opportunities afforded by their resources, which are to be utilised in some extent for the accommodation of paying patients. The probability that the example set, and imitated, by two of the chief metropolitan hospitals, will be followed by many other similar institutions, makes it advisable to reconsider carefully how far good will be likely to accrue to the public and the profession from a widespread adoption of the pay system. It will be remembered that we accorded a modified approval to the St. Thomas's plan, and that we expressed an opinion favourable to it so long as it may be carried out in a way that could not interfere with those interests it is our duty to conserve. Since, however, the actual working arrangements, the mode in which the duties are performed, and the manner in which grave responsibilities are distri-

buted at the St. Thomas's Hospital Home, have become known to us, we feel reluctantly compelled to express grave dissatisfaction with certain details in connection with it. We might have refrained from this, perhaps, had there been any apparent ground for hoping that changes would be introduced, having for their object the restoration of rights improperly usurped at present. But there is not; and in view of a possible immediate addition to the already existing public-private hospitals, we have no means open to us to pursue but the course on which we have entered.

The chief, and first, complaint we urge against the St. Thomas's Home is that the medical officer placed in charge of it performs even capital operations, and certainly such as, in the ordinary dependent class of patients, would only be undertaken by those surgeons of long and wide experience whose position on the staff is a guarantee of their ability. That the gentlemen appointed to superintend the Homes are in all respects admirably qualified to discharge the duties rightly falling to them, we do not doubt; it is the error of mistaking those duties that we especially condemn. The salary apportioned to the medical superintendent at St. Thomas's is, regarded as the emolument of a house surgeon, exceedingly handsome; but it is by no means sufficient to afford adequate remuneration to a surgeon of experience wide enough to justify him in entering unassisted on the performance of capital operations. We venture to think that such a consequence of his appointment was never anticipated by those who made it; but that it might have been looked for as a natural sequence where there was no special prohibition against it, is, now that we see the matter aright, clear to us. Patients whose condition necessitates operation, and to whom the prospect of saving the fees to be paid to a special surgeon is opened up by the readiness of the resident surgeon to take entire charge of their case, may perhaps be excused, if they decide to choose the less costly path, and submit themselves entirely to him. The injustice this entails needs no enforcing. Ignorant of all the niceties inseparably associated with the question, one man who is a surgeon may, and, as we know, does, often appear to a patient's understanding as good as another man who is a surgeon. The public cannot be brought to comprehend the long training necessary to make a good operator; and it is an utterly hopeless task to prove to them that the success of an operation is oftentimes only determined after the actual cutting procedure; that it is mainly the subsequent treatment on which recovery or death depends. We repeat the public will not—cannot, indeed—understand these details; and all the greater, therefore, is the injury they suffer in being permitted to elect whether they will confide themselves at little cost to an operator of small experience, or one of large experience, whose services are to be obtained only with a more considerable outlay of money. It would, perhaps, be better to avoid the other point suggested in the same connection, that, namely, of the injustice done to the profession by the reduction of the number of cases which would, but for the interference of the “Home” superintendent, be distributed among its members. We must, however, make this reference to it, and insist on the necessity of arresting at the outset the growth of a system which, if at all extensively adopted,

would lead to very considerable disasters, both to surgeons and to surgery. It cannot be denied that the mortality to be expected from the rash performance of important operations by eager youngsters, may be a serious objection to home hospitals in the future; and it is because we believe these institutions are capable of supplying a really existing want, and supplying it well, under judicious management, that we make this protest against the first evidences obtained of a tendency to strain their legitimate boundaries. To the house-surgeons as a body we can raise no objection at all. Their duties, even when rightly curtailed, will be heavy and responsible, and are deserving of pecuniary recompense at least as considerable as the salary given by the St. Thomas's committee. But we repeat, it is an absurdity to assume for a moment that any such inducement would be sufficient to tempt to the post men in all respects able to undertake the performance of the more important operations, many of which must be expected to be necessary in a hospital.

#### COMPULSORY NOTIFICATION OF INFECTIOUS DISEASES.

SOME of our morning contemporaries are waxing sorely wrath with Dr. Lyons, M.P., because, in compliance with the wishes of the great bulk of the medical profession, and of the more sensible of the public, he has blocked the progress of Mr. C. Dwyer Gray's Bill compelling the attending physician to become the direct informant to the sanitary authorities of the existence of cases of infectious disorders: and Mr. Gray addresses a letter to his own journal, in a most injured tone, complaining of Dr. Lyons's conduct, the more so as it was the members of the medical profession who first set him in motion upon this subject. This, of course, would be a damaging accusation, and it becomes necessary, therefore, that we should recall to our readers the real facts of the case, and briefly show that Mr. Gray has unintentionally put forward a representation not exactly in accordance with the real bearings of the question. We have a very distinct recollection of the occasion when Mr. Gray, M.P., then Lord Mayor of Dublin, was "put in motion" anent notification by a large and influential deputation of Dublin physicians and surgeons, which waited upon him at the Mansion House, and discussed the subject; and we heard with pleasure and interest his able speech in reply to that deputation. We have, however, an equally distinct remembrance of the observations of Professor Haughton, and of several other speakers, in which they distinctly acquainted the Lord Mayor that they considered that the medical attendant should not, under any circumstances, be the informant; but that this duty should devolve solely upon the occupier of the infected dwelling. With a few exceptions, the whole concensus of opinion was in this direction; and it is, to us, hard to understand how Mr. Gray can now state that he was "put in motion" by the medical profession to initiate a Bill the leading feature of which was the direct notification of what we are in a position to show that the Irish medical profession profoundly disapproves. Another morning contemporary accuses our profession of taking their decided stand

through a fear lest their material interests might be endangered. We would refer that journal to the published report of the deputation, which showed that the eminent gentlemen present were guided not by any mercenary or selfish view, but by the noblest motive which can influence a professional man—the desire of maintaining the standard of professional honour. Our lay contemporaries, no doubt under inspiration from certain quarters, blame Dr. Lyons for not allowing a select committee to be nominated to consider the question; we believe that our junior city member was perfectly right in the course he took. Were such a committee now appointed the result would be that a number of theoretical London sanitary reformers would be heard, along with a few select advocates of the system for this side of the water; the general body of the Dublin profession would have no opportunity of stating their views, and a Bill would be passed in haste which would be repented at leisure. The result of Dr. Lyons's judicious action is that the matter is adjourned until next year. In the meantime, a great many things will happen, and when it comes on again, if it ever comes on again, full, well-digested, and practical information will take the place of the crude theories and wild proposals which have, up to this, come under public notice.

In truth, the more the project is considered, the less it is liked. When first brought forward, about a year and a-half ago, at the Dublin branch of the British Medical Association, there was but one dissident, and a motion in favour of it was proposed and seconded by the two then Collegiate presidents, one of whom disclaimed the idea of any payment whatever being made to the notifying medical attendants for discharging the proposed duty. The two plebiscites of the medical profession, which have since been taken, show how completely medical opinion has altered; and it is a significant fact that the latest one recently taken by ourselves is much more hostile to the proposal than the earlier one of the Irish Medical Association. In the House of Commons, on the motion to go into Committee on the measure, Mr. Brooks, senior member for Dublin, went "solid" in its favour; but discussion with his constituents altered his views, and the palinodia at the recent dinner of the Irish Medical Association, was the result. We do not blame officers of health for their persistent advocacy of this project, for "'tis their nature too;" they regard the community with the same eye as the Civil Service examiners in Trollope's "Three Clerks," who wished that the whole population were divided into classes and sections, and severely examined as to their capacity for their several occupations. We deny that the bulk of the profession, or of the public, are in favour of compulsory notification by the medical man; we maintain that the present movement is the result of a conjunction of a few sanitary enthusiasts and corporate wire-pullers. A classic sage said "*festina lente*," and succeeding generations have recognised the wisdom of his remark. This is exactly what the advocates of notification will not do; their motto is *festina*, and we believe the bulk of our readers will yet thank Dr. Lyons for having added the *lente*.

### RECENT INQUIRIES REGARDING THE CAUSES OF TYPHOID FEVER.

WHENEVER an outbreak of what is now called typhoid or enteric fever occurs in a community an inquiry is instituted as to certain conditions upon which the appearance and prevalence of that disease are assumed to depend. These conditions include specific organic contamination of water or air, and contagion. Outbreaks of this nature having lately occurred at Haverfordwest and Totnes. A most careful inquiry into their origin was instituted by the Local Government Board. Abstracts of the reports submitted appear in another column, and the reports themselves bear internal evidence that throughout the whole inquiry to which they refer, attention was in a great measure directed to the discovery of evidence in support of these two theories, namely, specific poison and contagion. In the abstracts given it has been found convenient to italicise certain expressions, in view the more clearly to indicate the power intended to be attached to them, and how far they support the theories in question. Here, then, are some results thus obtained:—At Haverfordwest little light upon its causes; an assumption, but nothing positive, that the subject of the first case had visited an infected house; the occurrence of several cases in the month of August,—that is at the ordinary period when autumnal fever and diarrhoea usually happen; the localities unconnected with town sewers or water supply; the cases without direct communication with each other; no evidence of specific poison nor of contagion;—in fact, the occurrence of the outbreak inexplicable by either theory.

At Totnes, the very nature of some of the cases of fever doubtful; an impossibility to state, except vaguely and on assumption, that the disease had been imported or that it was of a specific infectious nature; that is, an admission that neither theory found support in phenomena; also that at the same time, in the same family, of cases of fever occurring, some were called typhoid, others typhus, any difference in their actual nature remaining undefined. And so, also, with regard to the several places included in the Rural Sanitary District of Totnes. In none of these could the evidence recorded be looked upon as demonstrative that the outbreak was, in any respect, due to either of those causes; or, in other words, that it was specific at all.

With reference to the above particulars the remark occurs that however objectionable "insanitary"—otherwise dirty—conditions of localities may be in themselves—and upon this point there is surely no difference of opinion—yet the existence of such conditions is by no means necessarily concerned directly in the causation of specific fever, neither are cases of fever, whether sporadic or epidemic, by any means confined to places where matters of conservancy are imperfectly attended to.

In order that the occurrence and prevalence of epidemic outbreaks of disease may be investigated fully and scientifically, it is necessary that inquiry should extend altogether beyond such limited sphere of observation as is furnished by conduits, gutters, drains, and sewers. Among other aspects from which such an investigation must be made if ultimate success be aimed at, are such as include the health, social and other conditions of individuals and communities, as well as conditions generally of the locali-

ties occupied by them; laws of periodicity, such as organic life, human as well as animal and vegetable, is subject to and influenced by; seasonal recurrence and peculiarities; meteorological conditions; among various others, that condition of air of which disease itself is only the test and measure, now acknowledged as epidemic constitution, and depending, at all events to a considerable extent, upon elements which "neither thermometer nor barometer, neither rain, nor wind gauge, nor measure of moisture, nor test of ozone, can reveal to us, but only our records of sickness and death." One year this "epidemic constitution" favours small-pox, the next, perhaps, scarlet fever, or measles, or whooping-cough, or "will, so to speak, select from several forms of fever that one which will fill the beds of our fever hospitals." But to confine investigation as to the great ultimate causes upon which decay, sickness, and mortality depend to such as concern only the sphere of the scavenger and nightman is not alone to ensure insuccess, but to prostitute and paralyse the functions of officials whose duty it is to advise comprehensively and from a scientific point of view upon the larger sanitary wants of the people.

### Notes on Current Topics.

#### The Presidency of the Royal College of Surgeons.

THE Senior Vice-President of the Royal College of Surgeons will probably be amused rather than seriously angry when he reads the vulgar self-assertiveness of a writer in the *Lancet*, who, in a pretentious note of tall talk, seems bent upon doing a stroke of business on his own account, or that of some friend. Under the heading given above, our contemporary last week, with unmannerly obtrusiveness, attacks Mr. Erasmus Wilson because, forsooth, he is *not the representative of English surgery—ergo*, he is not a fit occupant of the Presidential chair during the meeting of the International Congress. The paragraph runs thus:—"It would be both anomalous and unseemly for the College to choose for its President a gentleman whose professional reputation is simply a *dermatologist*." It is not a question as to whether Mr. Erasmus Wilson has done work well that few amongst us could do at all, and in his generosity founded a professorship in an important department of our art; not whether he has contributed his quota to physiology, surgery, science, and the general stock of knowledge; not whether, as a member of Council, he has performed his allotted task with satisfaction to his colleagues and to his profession; but simply that, by a sort of tacit consent, he belongs to that dreaded class known as *dermatologists*.

The neophyte who indulges in this "irresponsible frivolity," and puts it forth as argument is probably not aware of the fact that Mr. Erasmus Wilson won his spurs not as a dermatologist, but as a teacher of anatomy and surgery, and a writer of one of the best manuals of anatomy in the English language; that his many valuable contributions to physiology obtained for him the Fellowship of the Royal Society; and that his numerous papers on various branches of professional knowledge greatly assisted to secure the success of the *Lancet*, whilst

the writer of the "Annotation" we have referred to was acquiring the A. B. C. of his medical education. It is quite unnecessary on our part to add a word on the many valuable additions made by Mr. Erasmus Wilson to the pathological series of the College, and the munificent endowment by means of which a Pathological Curator will be added to the Museum at a salary of £170 a-year, and who will, in the future, doubtless do good service to surgery and medicine; but it would be, perhaps, too preposterous were we to imagine that any member of the profession would look to our contemporary as the arbiter of fitness for the presidential chair of the Royal College of Surgeons. The choice may be safely left in the hands of those so much more capable of judging.

### Summer Diarrhoea.

THE Local Government Board has entrusted to Dr. Ballard the very important duty of inquiry into the etiology of "summer diarrhoea." As a preliminary step to the more systematic investigation of his subject, Dr. Ballard solicits the aid and co-operation of members of the profession engaged in practice; and for the double purpose of facilitating and systematising inquiry, has had a series of "forms," arranged in book shape, for distribution among those who are willing to help him in his work. In the letter which appears in another column, Dr. Ballard gives full details as to the points regarding which information is solicited. One set of queries has reference, in the case of adults, to such points as residence, occupation, previous health, any concurrent disease; in that of an infant, to manner of feeding, preparation and cleanliness of food; while generally, individual and local conditions are to be noted. A second set of queries refer to these points in a somewhat greater degree of minuteness. What strikes one in glancing over both sets of forms is the circumstance that, whereas the very name of "summer diarrhoea" given to the disease to be investigated indicates an acknowledgment of its seasonal nature, special room does not appear to be left for remarks as to conditions incidental to the particular period of the year in which this disease practically prevails. Would it not be desirable to include among the points of inquiry such items as temperature, variation, hygrometric conditions, barometer, peculiarities and characteristics of weather, electric condition, ozone, &c. With regard also to the more purely medical aspects, such points deserve attention as the occurrence or absence of other diseases, whether sporadic or epidemic, more especially fever; while in respect to other diseases of the great organic kingdom, phenomena of disease, or exceptional, as presented by animals and plants, might with profit and advantage be considered.

### The Waste of the Army.

THE enormous extent to which "waste" takes place in the rank and file of the British army is sufficiently indicated by the circumstance that, in order to replace that expenditure, 36,000 efficient young men have annually to be withdrawn from civil life, while to obtain that number, 54,000 have to undergo the preliminary proceedings of enlistment and medical inspection. That some,

and it a varying quantity of this waste is due to casualties in battle, is but natural. That such, however, form but an inconsiderable portion of those to which soldiers are liable, is a fact which finds demonstration in the history of campaigns. Considering the trying nature of many climates in which the soldiers of England have to serve, it is no matter of surprise that casualties by sickness, including mortality and invaliding, far outnumber those by all other causes; and it seems natural that when schemes, of what has come to be called "reorganisation," have been discussed, the possibility of diminishing the waste in this way has ever been taken into account. But whereas from the necessity of things it is to service in India, that the greatest proportion of the total waste is due, there seems some reason to believe that measures intended to decrease it are "evolved" more from an English point of view than from an Indian. Thus it is stated, and, in a way, correctly stated, that the ratio of mortality in India has undergone an enormous decrease since the introduction of short service. A very interesting, and most explanatory table in relation to these points, appears at page 138 of the Army Medical Report for 1878; it refers only to the Presidency of Bombay, but may be taken as approximately illustrative of conditions throughout the country generally. According to that return, and restricting the analysis to private soldiers, in 1869 the ratio of deaths per 1,000 strength was 20·98; of invaliding, 24·54, equal to a total loss by these causes of 45·52; in 1870, respectively, 15·73 and 24·13, equal to 49·86; in 1871, similarly, 12·27 and 22·77, equal to 35·04, thus showing a striking and satisfactory decrease in both items, and for the three years an average rate of mortality equal to 16·32; of invaliding, 27·14, or total, 43·46. Taking now the figures shown for the three latest years noted in the same document, the following are the results obtained, namely: In 1876 the rate of mortality in the same class showed the very satisfactory figure of 12·07; on the other hand, the ratio of invaliding was 47·52, making the total waste by these two causes, 59·59; in 1877, respectively, 12·01 and 47·50, equal to 59·51; in 1878, that is, the latest year for which statistics were available, the ratios were 19·33 and 57·29, equal to a total of 76·62; the general average of the three years respectively, 15·47, 50·77, and 65·24. Here, then, according to hard dry figures, a rate of mortality is shown for the first three years equal to 16·32, as against 14·47; of invaliding, 27·14, as against 65·24; or, in other words, the waste by disease in the latest period was 21·78 per 1,000 greater than in the first. So much then for the terms upon which a diminished rate of mortality is shown. And this, too, in the face of all that has been done for the soldier in respect to hygienic and medical management. So many men are sent back to civil life with impaired health; few, it is feared, with pension, but all with diminished prospects and capacity of earning a livelihood, consequently possible candidates at no distant period for hospitals, poor-houses, or even less desirable institutions. How far purely military efficiency has, or has not, gained by the system of short service, comes not directly within the scope of a medical periodical. But this phase of the subject is made tolerably clear in the records of recent campaigns.

### Domestic Economy.

AN excellent work is being accomplished by the Association which, during the past week, has been sitting in congress at the rooms of the Society of Arts, and at the Albert Hall, &c. The aim of the congress, which meets yearly, is to stimulate improvement in the way of domestic arrangements and health-saving; and among the papers read before it bearing on the subject held in view by its members, have been several of real and practical importance. Especially is this the case with an address delivered on Friday last by Mr. J. J. Pope, M.R.C.S., on "Health in School Rooms," in which denunciations were hurled at the dungeon-like underground schoolrooms connected with churches and chapels in London. The style and arrangements of board schools, moreover, were disparaged by Mr. Pope, and all who, like him, have carefully considered the utter unfitness of many of the costly buildings erected by the School Board for the purposes of educating healthy children, will agree with the conclusions arrived at by him. He especially insists that children should be taught the value to themselves of perfect ventilation, a point on which, as well, Lady Strangford emphatically insisted in a paper on "Teaching the Laws of Health in Elementary Schools." This lady goes the length of saying that the training of a child to live rightly should precede the teaching of the alphabet. We cannot help thinking Lady Strangford, and the domestic economists with her, have a just appreciation of the needs of young children. May they see them supplied.

### A New Medical School for Manchester.

A SCHEME has been put forward to provide Manchester with a medical school nearer to the infirmary than is the Owens College, which college is about a mile and a-half distant from the hospital. There is a reason for this attempt more than usually exists in such cases, and it may be questioned whether the absolute removal of the Old Pine Street School was altogether a wise proceeding, especially as events have turned out. There is a large number of good men in Manchester ready and able to teach well and successfully, and if their endeavours succeed in simplifying the processes of study to the Manchester student, they deserve the opportunity of making the attempt. Naturally the movement will be vigorously opposed, and there may be apparent grounds for opposition; but, to put a case, what student in London would not grumble at being compelled to journey a mile and a-half from the lecture room to the ward, and would not hail any arrangement to enable him to avoid the unpleasant and unprofitless exertion? We shall await the development of events in Manchester with some interest.

### The Electric Light.

ON last Saturday the prospectus of a new company to take up the electric light was circulated throughout Dublin. This Company proposes to work the well-known Brush system with a capital of £150,000, and they have secured exclusive arrangements for Dublin with the patentees. As the present contract for public gas lighting will shortly expire, and is not likely to be renewed, we may look forward to having our streets, railway

stations, and other large establishments, soon lighted by this new brilliant medium. It is likely that there will be a fresh panic in gas shares, but this is not called for. There are two methods of electric lighting—the "Arc," where the electric spark flashes from one point to another, and the "Incandescent," where some resisting material is rendered white hot. In Edison's lamp the resisting material is carbonised card-board; and in the Swan lamp manilla fibre covered with charcoal. In both cases combustion is prevented by the incandescence taking place *in vacuo*. Still, the incandescent material does not stand for any length of time, and for this reason we consider this principle of electric lighting radically bad. The lighting of large spaces by the "Arc" is now a possible, and will speedily be an accomplished, fact. The illumination of private houses is a problem of the future, but we have no doubt that it will soon be solved. Another difficulty is a machine which will measure the quantity of electricity consumed, after the manner of a gas meter. All these matters, however, are questions of a few years, or perhaps a few months; and we are convinced that gas lamps will be to our children the same tradition as street oil lamps are to ourselves. Still there is a great future before gas as a means of cooking and warming. One of the immediate results of the present movement will be the reduction of the present scandalously high charge made for gas by the Dublin Company; for it is simply absurd that the citizens should be paying a *reduced price* of 3s. 11d. for an article which in Belfast costs about half as much.

### The International Medical Conference.

THE arrangements for this great professional *reunion*, are rapidly approaching completion, but we fear that great extravagance is characterising the managers of the concern. They have between £6,000 and £7,000 at their command, but are calling for more money. It appears that the transactions (a copy of which will be given to each member), are to cost £5,000, or may cost £6,000. Surely, this is too much. What will our readers think, however, of the proposal to spend £250 on striking a medal in honour of the meeting, to be distributed among the members? One side of the medal will display a design by John Tenniel, the eminent draughtsman of *Punch* (is this merely a coincidence?), and the other the head of Her Majesty, and the names of the President of the College of Physicians, and of the General Secretary. If this were done in Dublin, it would be called advertising. We are sure that these eminent gentlemen would have the most righteous horror of any such proceeding as advertising themselves.

THE annual rates of mortality last week in the principal large towns of the United Kingdom per 1,000 of the population, were—Bristol 15, Leicester 16, Leeds 17, Portsmouth 17, Nottingham 17, Birmingham 17, Bradford 17, Brighton 18, London 19, Sheffield 19, Hull 19, Salford 20, Sunderland 20, Newcastle-on-Tyne 20, Oldham 20, Manchester 21, Norwich 21, Wolverhampton 22, Glasgow 22, Liverpool 24, Dublin 25, Plymouth 27, and Edinburgh 28.

### Criticism on the Medical Profession.

It may well be doubted whether any good result is likely to follow from serious consideration of the silly criticisms which emanate from lay writers from time to time on the medical profession. As a rule, these tirades are published in little read, and less readable organs, which depend on sensation stirring for the creation of such tiny flashes of interest in them as do sometimes illuminate their decay; and recently it has been the fashion with them to find the substance of their attack in the utterly nonsensical ideas of the structure and functions of the medical profession entertained by laymen as a rule. One such article, of more than usual virulence, appeared not long ago; and it has, from its very absurdity, attracted a share of attention. We had been hopeful that it might have been allowed to do the little harm it was capable of, and be forgotten, but the trust alas! was vain. It is to be replied to, so we learn, by, of all men, Dr. W. B. Carpenter. If Dr. Carpenter can be taken as an exponent of medical practice, as it obtains at present, then, of course, it is right for him to write on "the morality of the medical profession." We should have supposed, however, without this proof, to the contrary, that one who has so little associated himself with the active exercise of his profession, would have been somewhat diffident of his powers to adjudicate on its morality, a quality after all, intimately bound up with its practice. It may be, of course, that Dr. Carpenter has perceived the matter in a new light; but, in any case, we trust he will not be deterred from giving vigorous utterance to the just indignation felt by every medical man against the authors of disreputable attacks on those who follow medicine as a profession.

### Resection of the Human Kidney.

At the last meeting of the Medico-Chirurgical Society among the patients brought forward was the man on whom Mr. Clement Lucas successfully performed nephrectomy in February, 1880. This man, who is thirty-six years of age, looked ruddy and well, and free from pain and all symptoms of the scrofulous pyelitis, for which extirpation of the left kidney was undertaken. The wound is soundly healed, and there has been no sinus since Christmas. This is the first case in which the operation has proved successful on an adult in this country. In fact, what with this operation, with Billroth's removal of a schirric pylorus and an Italian amputation of the entire tongue, larynx, and tonsils from the one patient, the old surgeons must be getting rather astonished. Dublin students are talking of these surgical heroics, and wondering that our local champions are not bestirring themselves more out of the beaten track. We have little doubt but that Dublin will see some sensational surgery next session.

THE name of Lister has been further immortalised by the manufacture in America of an antiseptic fluid, of thyme, eucalyptus, gaultheria, and mentha arvensis, to which the makers have attached the suggestive title of "Listerine." Our distinguished *compère* will, no doubt, feel flattered with this very original idea.

WE note with great pleasure that the epidemic of small-pox appears to have, at least for the present, disappeared from Dublin.

THE New York courts have awarded 3,500 dols. (£700) damages to a little girl of that city for the loss of a piece of her nose, from the bite of a monkey that had escaped from the Bowery museum.

A BOSTON contemporary states that one of their leading physicians who advised a dyspeptic to take plenty of exercise, was quite taken aback when the patient remarked that he was a postman.

THE honorary membership of the New York Medico-Legal Society has been unanimously conferred on Mr. Jabez Hogg, Consulting Surgeon to the Royal Westminster Ophthalmic Hospital.

H.R.H. THE PRINCESS CHRISTIAN opened a grand bazaar in Bloomsbury last week, in aid of a fund for the new wing of the Hospital for Paralysis and Epilepsy, Queen's Square. This addition is to cost £9,000, of which £7,000 have been already collected or promised, and it is hoped to wipe off the balance by this bazaar.

WITH the decline of small-pox in London, our transatlantic brethren are unfortunately experiencing an opposite state of things in some cities. In Philadelphia last week there were 146 cases, of which 35 were fatal. Since November last there have been nearly 5,000 cases of small-pox in the city, of which over 1,000, or 1 in 5, died; a much larger proportion of fatalities than we are accustomed to witness from this disease.

In the principal foreign cities the rates of mortality, according to the latest official weekly return, were in—Calcutta 28, Bombay 36, Madras 38; Paris 27; Geneva, 18; Brussels 20; Amsterdam 20, Rotterdam 20; The Hague 20; Copenhagen 19, Stockholm 30, Christiania 23; St. Petersburg 65; Berlin 26, Hamburg 25, Dresden 19, Breslau 28, Munich 31; Vienna 31; Buda-Pesth 34; Turin 26; Venice 22; Alexandria 31; New York 27, Brooklyn, 20, Philadelphia, 19, Baltimore, 20 per 1,000 of the various populations.

FROM diseases of the zymotic class last week in the large towns measles showed the largest proportional fatality in Sheffield, Liverpool, and Bristol; scarlet fever in Wolverhampton, Hull, Edinburgh, and Nottingham; and whooping-cough in Leicester, Plymouth, and Liverpool. The 30 deaths from diphtheria included 10 in London, 6 in Portsmouth, and 5 in Glasgow. Small-pox caused 92 more deaths in London and its outer ring of suburban districts, 3 in Liverpool, and not one in any of the other large towns.

## Scotland.

(FROM OUR NORTHERN CORRESPONDENT.)

**EPIDEMIC MEDICAL LITERATURE.**—We have been somewhat roughly handled (we are determined to have our lives insured) recently for what we deemed, and intended as, a kindly notice of one of those advertisements "with the author's compliments," with which the profession is considerably familiar. When will their writers begin to understand that in this form these manifestoes become public property, and are as such amenable to criticism? A highly-respectable practitioner of long standing in Glasgow began lately to read one of these "introductorys," when he was suddenly reined up by "inverse ratio," tore the pamphlet to pieces, and pitched it into his waste-paper basket. It is a common observation that men affect scientific jargon in proportion as they are ignorant. A man who began life as a "sweetie-boy" is certain as a full-fledged doctor—generally of St. Andrew's—to manifest a gushing familiarity with the armamentaria of science and philosophy. In a city which boasts of a medical journal edited by Joseph Coats much literary eccentricity is to be expected. We make every allowance for that. But to show that our recent criticism was both kind and lenient, now that we are put to it, we offer a good prize to anyone who can extract either sense or decency out of the following specimens from the production in question:—"After a long period during the barbarous ages." "However, until the seventeenth century no decided advancement can be observed; but then, by a more careful study of anatomy, and as a result of painstaking observation at the bedside, new floods of light flashed upon them." Upon what? On anatomy and the bedside! Specimen of metaphor—the same "light" evidently brought forward "The light of truth dim in the past, and growing brighter in its course, now seems to shine with a mid-day brightness upon the hidden functions of our life." How does the learned lecturer know that the "light of truth," burn it ever so brightly, shines on that which is hidden? "In the olden times midwifery practice remained exclusively in the hands of matrons. They were usually women [what, in the name of wonder, could matrons be?] of middle age, selected because they were handy at the bedside. As a class, they had little or no special instruction for it,"—the bedside! "During this interval the public had begun to realise the value of a male obstetrician over a female one!!" We sincerely hope this is to be taken in a Pickwickian sense. "From the many deaths which have occurred under the administration of chloroform in surgery, some anxiety and risk is felt each time it is given." As for "Diascorides," we have instituted inquiries, and the most reliable point to his having been a member of "the Glasgow Southern Medical Society." We have quoted sufficient to show the leniency of our former critique; and we have returned to the subject solely in self-defence.

**DR. HENDERSON'S "EPIDEMIC INFLUENZA."**—We are informed by a medical gentleman in Glasgow that he had a patient who suffered from the Helensburgh "influenza" for six months! This disposes of the question as effectually and as absolutely as the analyses of ten thousand chemists.

**GLASGOW BRANCH OF THE BRITISH MEDICAL ASSOCIATION.**—The annual meeting of the Glasgow and West of Scotland Branch of the British Medical Association was held in the Faculty Hall on Friday the 24th inst. :—Dr. Bruce Goff of Bothwell, resigned the presidential chair in favour of Dr. Yellowlees, of the Gartnavel Lunatic Asylum. The

members were driven out to the Asylum—but were driven back again. At the Asylum Dr. Yellowlees delivered his presidential address. In the evening there was a dinner. We may possibly refer to some of the proceedings in our next.

**ANDERSON'S COLLEGE, GLASGOW.**—The annual meeting of the trustees of Anderson's College was held last week, Mr. J. L. K. Jamieson presiding. The annual report stated that Dr. Stenhouse, F.R.S., of Pentonville, London, who died on the 31st of December, 1880, by his will dated 3rd of October, 1878, bequeathed the sum of £900 to the College for providing a scholarship for the chemical classes of the College. Dr. Abraham Wallace was elected to the Chair of Midwifery, and Dr. David Taylor to that of Dental Anatomy. The managers were at present negotiating with the directors of the Royal Infirmary as to the amalgamation of the two medical schools, and will lay the result before the trustees before coming to any arrangement. The number of students attending the various classes, so far as returned, was 2,082. The report was adopted, and the managers and professors were afterwards re-elected.

**THE MEDICAL OFFICER OF HEALTH FOR ABERDEEN.**—At a meeting of the Aberdeen Town Council last week, Dr. W. J. Simpson, of Dover, was elected. The duties of the office are those of medical officer, police-surgeon, medical attendant at the Epidemic Hospital, medical attendant at the gas works, examiner of the quality of the gas, inspector of dairies, cowsheds, and milkshops, and some general duties of a mixed kind. The salary for the above is £300 a year, with quarters in the Epidemic Hospital, coals and gas. It is reported that in order to accept the above, Dr. Simpson is giving up a practice of £700 a year. Those in Aberdeen, who are awaiting the dawn of the millennium, should at once proceed to Dover.

The salary of the Aberdeen medical officer is divided, according to his several duties, which gives the Council the power of removing him in easy stages, without a direct dismissal, by appointing separate officers to perform his several duties. Dismissal, in fact, by a process of slow starvation, a method not unknown to local authorities in England.

**THE SCOTCH CORPORATIONS.**—The existence of a Royal Commission has thrown these bodies into a state of feverish excitement. The members of the several Councils are greatly exercised in their minds as to the best methods of defence; some propose an imitation of Turkish tactics, of procrastination, others are for wholesale reform. A third party, seeing everywhere only enemies, are ready to exclaim with Achmet Pasha, when he found himself surrounded by Russians, "It is kismet," and bolt. As purely examining bodies, their days are numbered, as teaching bodies, they may long live as honoured institutions. The Government can examine for civil practitioners, as it does now for the army and navy; why, then, continue a condition of things which has no advantages, and many disadvantages? The Colleges have funds enough to provide for courses of lectures, which might be open to qualified practitioners, thus affording a means of placing the latest methods of treatment and practice before the hard-worked members of our profession. To suggest such a course to some of the Fellows of the College of Surgeons, is to run the risk of throwing them into a state of violent convulsions. "They are an examining body, and not a teaching body," is the statement of not a few; time will show if they are even that, and what will become of the "Fellowship distinction." Should the Government decide on a one-portal admission to the profession, but require affiliation to one of the Colleges for "moral supervision" of the members of the profession, the

Edinburgh College is doomed. The College now lives on its share of the double qualification fees, the "Fellowship distinction," and on candidates who have not studied in Edinburgh. In the presence of the Royal Commission, the College of Surgeons is willing to give up its single licence if the College of Physicians will do the same, but the latter does not see its way to do so. The physicians would lose much, the surgeons very little. This show of virtue on the part of the College of Surgeons is very touching.

**A CASE FOR MEDICAL JURISTS.**—At the High Court of Justiciary, Edinburgh, on Monday, the 20th inst., six young men, from the prison of Inverness, were charged with assault, one being further charged with that of rape, and the others with aiding and abetting him. The indictment set forth that on the 10th April last the prisoners assaulted a young man residing in Inverness, and a young lady who was with him, and after the former had been rendered unconscious by their violence, that one of them seized the latter by the neck, threw her over a rock upon the ground, and criminally assaulted her, the others aiding and abetting. With the exception of one, found not guilty, the remaining prisoners were found guilty as libelled, including the one alleged to have committed the assault. It strikes us as extremely strange that so many young men would conspire to commit so infamous a crime, and not less strange that the assault could have been committed under the circumstances. Are there no other particulars with which the public have not been made acquainted?

**MONUMENT TO DR. ROBERT MACNISH, OF GLASGOW.**—We are pleased to learn that a monument has been placed in St. Andrew's Episcopal Churchyard, to the memory of the accomplished Dr. Robert McNish, author of the "Anatomy of Drunkenness," "The Philosophy of Sleep," &c.

## Correspondence.

### GOVERNMENTAL INQUIRY INTO THE ETIOLOGY OF SUMMER DIARRHŒA.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Will you permit me to address you, and through you my medical brethren about the Kingdom, on the subject of the large and most important inquiry into the etiology of "summer diarrhœa," with which the Local Government Board have charged me.

It is an official inquiry, but from the first I have perceived that it would be impossible, even were it desirable, to conduct it altogether through official channels. Naturally I have looked for help first of all to medical officers of health. Among these are many earnest workers that I am personally acquainted with, whose willing aid in the collection of facts I have enlisted, and who are taking upon themselves much labour in my behalf. Through medical officers of health I am seeking to obtain such minute details of statistical information respecting mortality as are necessary for my purpose. There are many of these officers that I have been anxious to confer with, but time and opportunity have been against me. I shall be glad of volunteers.

But there is another and important class of facts which can only be supplied by men engaged in medical practice—namely, facts which relate to summer diarrhœa as a disturbance of the system of the individual or a disease (fatal or non-fatal). As such it is met with in all ranks of society and at all ages, although its fatality is apparently greatest in certain ranks and at certain ages. Various hypotheses have been advanced to account for the summer incidence of the disease, and for difference in its fatality; and all these hypotheses will have to be passed under consideration. My difficulty is to obtain data accurate and sufficiently numerous, to enable me to estimate their value, and for these data I now make an appeal to the members of my own profession, in the full belief that there are many among them who will feel an interest in the subject, and that I shall not

appeal in vain. Especially I beg for aid from such of my brethren as practice among the well-to-do classes of the community. I particularly want to discover whether summer diarrhœa is a disease of equally frequent occurrence among the well-to-do and among the poorer classes, the rate of fatality of it when it does occur among different classes of people, and the circumstances under which the illnesses happen.

In order to facilitate the giving of the information I require, I have prepared, and am now issuing to those practitioners who will kindly help me, small pocket note-books, patterns of which I enclose. I think that you will see that in these books I have reduced my actual specific inquiries to a minimum. One of the books is for the record of individual cases of diarrhœal sickness; the other is complementary to it, and has for its object to ascertain, with some approach to accuracy, what is the practice of mothers in respect of the feeding of infants at different ages, in different ranks of life, and in different parts of the country. Any required number of these little books will be furnished to medical men who are willing to use them, on their writing for them to me at the Local Government Board, Whitehall.

I am, Sir,

Your obedient servant,

EDWARD BALLARD,

Local Government Board, Whitehall, S. W.,  
20th June, 1881.

### CALF LYMPH.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The recent epidemic of small-pox in the metropolis has put a practical aspect on the question as to the relative values of calf and humanised vaccine lymph.

Before resorting to the employment of the bovine virus I deem it essential to ascertain the source and nature of this lymph, which is being so warmly advocated and widely advertised.

My investigations have led me to the conclusion that calf or animal lymph is a name applied indifferently to at least three different commodities possessed of the most entirely different properties.

1. There is the lymph obtained by Messrs Coely, Badcock, Burrows and Thiele, by inoculating the cow with the human small-pox virus; this, however, it would appear from the conclusive experiments of the Lyons Commission, never produces cow-pox, when it produces anything, it is true small-pox, and capable of propagating that disease by infection.

2. There is the lymph obtained by inoculating the calf with ordinary humanised, retro-vaccination as it is called; a plan which fails at the outset, since it does not insure the elimination of the much dreaded human impurities.

3. And this is the common source, there is the lymph got from cases of *spontaneous* cow-pox, and propagated on a series of heifers. This (bovine disease apart) would commend itself warmly to the minds of many, but strange to say, this very lymph has been denounced in no measured terms by "the immortal Jenner" as unprotective against small-pox (pp. 7 and 8 of Jenner's Inquiry.)

I trust you and your readers will kindly explain my difficulty, and set me right if I be in error.

I am, Sir,

Yours obediently,

W. J. COLLINS, B.Sc., M.R.C.S.

St. Bartholomew's Hospital,  
Smithfield, 20th June, 1881.

### DR. I. D. BULKLEY'S NEW METHOD OF EPILATION IN FAVUS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Favus is a skin disease which we in London see little of, but those of us who have any experience of Parisian skin-disease hospitals, know that it is common enough in France. In Scotland too, from some unexplained cause, it is far more prevalent than in the rest of the British Islands. In the United States, we are informed by Dr. Bulkley, in a very interesting monograph (Putnam, New

York, 1881), that the disease is also very rare, having been noticed only 47 times in 28,000 cases of skin disease seen by certain practitioners.

When deeply seated, it is extremely difficult to cure this parasite affection of the skin, especially when, as is usual, it affects the hair follicles of the scalp. It is in such cases as this, that epilation has been found to be imperatively necessary, and those practitioners who have had the greatest experience in skin diseases, are accustomed to have recourse to extraction of the hairs by means of different kinds of forceps. Before this epilation by forceps was used, the old-fashioned plan of the Frères Mahon was in vogue in the Hôpital Saint Louis of Paris. That consisted in putting on the diseased head a plaster of pitch, which adhered to the hairs, and was then removed as carefully as possible, but which often caused a great deal of pain to the patient.

Dr. Bulkley, of New York, has, it seems, taken a leaf out of the book of these Saint Louis ringworm curers, and has recently devised a method for the extraction of hairs which seems likely to prove of great service. He has had sticks of very adhesive material fabricated, which can be melted and made to adhere very firmly to the diseased hairs, and which, when cold are forcibly removed, drawing numbers of hairs along with them. The mixture he has found to succeed well is the following: yellow wax, 3 drachms; lac in plates, 4 drachms; resin, 6 drachms; burgundy pitch, 10 drachms; and dammar gum, 1½ ounces. After these ingredients are thoroughly incorporated, the mass is rolled into sticks of various sizes, from ¼ to ½ of an inch in diameter and from 2 to 3 inches long.

The hair is cropped short, about ¼ of an inch in length, at the diseased spot. The end of the stick is heated in the flame of a spirit lamp, and pressed on the hair until it rests on the scalp. It is left until it is cold and then bent over, drawing out the hairs as it is withdrawn, not without pain. After epilation, a 4 grain to the ounce bichloride of mercury is rubbed in. This seems to be really such an improvement in the practical treatment of bad cases of ringworm and favus, that I think it merits notice from all who have to treat these tiresome complaints, which most practitioners have sometimes to do.

Yours faithfully,

C. R. DRYSDALE, M.D.

17 Woburn Place, W.C., June 19th, 1881.

#### THE ROYAL COMMISSION ON THE MEDICAL ACTS.

Continued its sittings on Friday and Saturday last at its offices, 2 Victoria Street, London.

Lord Camperdown the chairman of the Commission, the Bishop of Peterboro', the Master of the Rolls, Sir W. Jenner, Professor Huxley, Professor Turner, Dr. Robert MacDonnell, Mr. Simon, Mr. Sclater Booth, and Mr. Coyne were present. The first day was occupied by the evidence of Dr. Jacob, of Dublin, and the second with that of Dr. Glover, who represents *The Lancet*, and with the further examination of Dr. Humphry of Cambridge, President of the British Medical Association. It may be assumed that the evidence of all these witnesses was strongly in favour of reconstruction of the Medical Council, and of direct representation as a means of such reconstruction; and it is to be hoped that they have succeeded in satisfying the Commission that no settlement of medico-educational affairs can be either acceptable or practical which does not give to the profession its proper place in its own government.

#### UNION HOSPITALS AND THE ROYAL IRISH UNIVERSITY.

A COPY of the Memorial is now in the hands of each member of the Senate. Lord O'Hagan has kindly promised to forward to the proper quarter the official copy for the Senate at large. It cannot be known whether a deputation will be received or not until the Senate meet. Meanwhile, the depu-

tation ordered by the Conference of June 6th, and consisting of Drs. Adrian, Kenny, Daly, O'Reilly, and Laffan, applied for an interview with the Dublin clinical physicians on the Senate. The interview was arranged to take place at the house of Dr. Hayden. Dr. Cruise wrote previously promising all his support in the Senate; Drs. Lyons and Banks were detained unavoidably elsewhere. Dr. Hayden received the deputation most cordially, and declared he agreed with every word of their Memorial, and was heart and soul with them. Dr. Laffan pointed out the advantages which physicians, patients, students, science, and all parties, including the new University, would gain from giving provincial physicians a share in clinical teaching. Some remarks were also made as to the necessity for creating some ties between the Dublin profession and that of the provinces. After warmly thanking Dr. Hayden, the members of the deputation withdrew. Subsequently they waited by appointment on Lord O'Hagan. As a *précis* of the interview is at present in the hands of his lordship's secretary, it will not be published till a future day.

WE understand that Her Majesty the Queen has selected Dr. James Reid, of Ellon, Aberdeenshire, to take temporary medical charge of the Royal Household in Scotland, pending the completion of the new arrangements rendered necessary by the resignation of Dr. Marshall on account of ill-health.

H. R. H. the Princess of Wales, accompanied by three of her children, visited the Hospital for Hip Disease in Children, Bloomsbury, on Sunday last, and were conducted through the various wards of the Hospital by Mr. Howard Marsh, F.R.C.S. The Royal Party went from bed to bed speaking to each child and distributing both fruit and flowers. Her Royal Highness on leaving expressed herself much pleased with the Hospital, and gave permission that it should henceforth be known as the Alexandra Hospital for Hip Disease in Childhood.

### Literature.

#### TRANSACTIONS OF THE OBSTETRICAL SOCIETY OF LONDON (a).

THE London Obstetrical Society holds first place among the kindred associates, founded as they were, to promote the advancement of the study of obstetrics and gynecology. The volume now before us contains many communications of interest, including some which treat of subjects of great importance, of these mostly, the papers by Mr. Knowsley Thornton, "On the Removal of Uterine Fibroids by Laparotomy," and Dr. Clement Godson's case of "Removal of Fibrous Outgrowth from the Fundus Uteri," are those which claim the greatest attention.

Mr. Knowsley Thornton partly points out that hysterectomy is on its trial, and if his views are supported by the experience of others, as we trust they will be, we believe that this important operation will, for the future, be by no means unfrequent.

He commences by enumerating the chief objections to the operation. 1st. That uterine fibroids differ from ovarian tumour, because they do not of necessity progress to a fatal termination. 2nd. That they are more often relieved or checked in their growth, or cured by medical treatment, or by surgical procedure of a *simple and comparative safe nature*. 3rd. That the operations for the removal by laparotomy are much more dangerous to life, than are similar operations for the removal of ovarian tumours. The italics are our own. We entirely disagree

(a) Transactions of the Obstetrical Society of London for 1880. Vol. XXII.

with the writer in saying that the operations advised for the removal of fibroids per vaginam are either "simple or safe." But we entirely agree with him in his dictum, that "fibroids more often kill than is generally believed."

The real question, however, to be decided is, are operations for the removal of uterine fibroids by the abdominal section, more dangerous to life, than similar ones for the removal of ovarian tumour, and is it justifiable in cases of fibroid tumours of the uterus, which resist medical treatment and which are evidently killing the patient though it may be slowly. As to the first it must at present be admitted, that these operations are more dangerous than ovariectomy. But as to the last Mr. Thornton's case now recorded in addition to those previously reported, may be considered as a decided answer in the affirmative. His paper and the discussion will well repay a careful perusal. Dr. Braxton Hicks, gives interesting details of a case of extra-uterine foetation, in which an unavailing attempt was made to save life, after the rupture of the cyst; in the discussion which followed, two important and as yet undecided methods of treating such cases were brought forward for consideration, one by Dr. Routh, who advocates destroying the life of the child by injecting morphia into the amnion. The other the propriety of performing gastrotomy "primarily," in cases of extra-uterine section, once the actual condition of the patients has been definitely ascertained. Such discussions as followed in these papers, put prominently forward the value of this society.

Taken as a whole, the volume before us is quite up to the average of former years, while the reports of the discussion are admirably reported.

#### MORALITY. (a)

WE have found it extremely difficult to review this little book, so utterly different is it from anything of the nature of scientific work, alike in style of thought and mode of expression. Our first difficulty, indeed, was to find out what the author had written. So much of the book consists of extracts in inverted commas, and so much more of notes, written by every one in the world, except the author, that we finally came to the conclusion, based on the author's repeated statement to that effect, that, "the italics were his own."

Joking apart, however, the aim and object of the little book is an exceedingly good one; it is to induce young men to lead pure lives; and with this view, every consideration of morality, religion, and preservation of health, is successively put before them. It is only to be lamented, that such motives should have so little weight with the majority of young men. None but medical men can know how widespread are the ramifications of the terrible disease induced by promiscuous intercourse, and how fearfully it falls, in later and more sober years, on the chaste wife and innocent children of the offender, aye, even when he himself is apparently recovered from it. We should think it desirable that the probability of such results should be fully set before young men, if possible before they have yielded to a temptation, the strength of which will increase with every successive indulgence. And by no one, we think, could this be better done than by the physician of the family or the school. The motives for maintaining chastity which he will set before a lad may doubtless be much lower than those which a clergyman will offer, but the dangers which the physician will point out are so much nearer at hand, and are regarded by most persons, rightly or wrongly, as being so much more certain of infliction, that it can hardly be doubtful they will prove much the more operative. And such warnings ought to be given early, before a lad is likely to have yielded to his first temptation. One of the most utterly abandoned men we have ever met once said to us "No need for a young man to go astray at first, but if he once falls he can never afterwards recover himself, so much more imperative does the desire for intercourse become, when it has once been yielded to." There is another subject, which Mr. Hime avoids, and rightly, but there is no reason why we should not take this opportunity of enforcing the duty of a like precautionary warning against it. We mean the early practice of secret vice. We would think it the imperative duty of every school or family physician to warn every boy against this vice, before he should reach the age of twelve years. No explanations need be given; but the terrible results of a blighted life, a

ruined manhood, insanity, paralysis, &c., should be set forth in the plainest and strongest terms. How much wretchedness would be avoided in after life, if such early warnings were fully and emphatically given. Fathers are careless and confident; clergymen consider they have nothing to say to a matter which will cause no open scandal; it is the physicians province, a matter of health rather than morality, and one which undoubtedly we ought never to neglect.

Mr. Hime rightly points out that intemperance in alcoholic stimulants is one of the great causes of indulgence in sensual vice, and that to avoid the one will materially assist in the avoidance of the other. He also leans strongly on the point that, "to take it out of ourselves," as the saying is, by exercise and hard work, is one of the best aids to the maintenance of chastity. Mental occupation, he points out, is no less a means to this end. The motives he draws from religion, moral considerations, a sense of what is due to others, and finally of what is due to ourselves regarded from the highest standpoint, as a creature of moral nature, which is outraged by impurity, all these considerations, as put by Mr. Hime, and his collaborateurs, we fully approve of, but a medical journal is not the place to enter fully on a discussion of them.

We shall conclude with one quotation from Mr. Hime, we mean from Mr. Patmore, whom he has quoted, assigning a motive for purity of exquisite beauty, but we fear only too little recognised.

"They safely walk in darkest ways,  
Whose youth is lighted from above,  
Where through the senses' silvery haze,  
Dawns the veiled moon of nuptial love.  
Who is the happy husband? He  
Who, scanning his unwedded life,  
Thanks Heaven, with a conscience free,  
'Twas faithful to his future wife."

Mr. Hime has expanded the same idea in prose; and quoting, of course, a beautiful passage from Father Lacordaire, or rather from Mr. Black, who quotes the Pere, has shown how the maiden living faithful to her future husband, though as yet she has never met him, has a right to expect a similar fidelity from him to herself. A

#### MERCY TO ANIMALS. (a)

THE accomplished editor of the *Leisure Hour* has very ably espoused the cause of the dumb creation in a little volume entitled "A Plea for Mercy to Animals." In it he claims for all things that suffer the right of protection at the hands of man; and with much that he urges against the inhuman practices sanctioned under the name of sport, by the usage of ages, in this country, very many readers will agree. Naturally, we are unable to follow Dr. Macaulay's indictment against science; and, because his little book is in its other part well and reasonably, though, perhaps, a trifle oppressively, conceived, we the more regret the blindness that leads him—a medical graduate, too—so far astray when dealing with a purely scientific problem. It is a matter of much moment when a member of the medical profession ventures to publish the assertion that vivisection teaches nothing "because the differences of structure and function diminish the chance of any light being thrown on human physiology by such means." Has Dr. Macaulay ever ascertained what are the data of physiology? Does he appreciate the importance of physiology in therapeutics? And has he any acquaintance with the true outcome of scientific experiment? One is prompted to put these questions from the manner in which the charge against vivisection is made and supported by evidence of an *ad captandum* character. The authorities that are quoted in defence of retrogression are not those likely to carry weight to the mind of an educated scientist; and we repeat, it is a pity Dr. Macaulay was not content with making a less sensational and more rational appeal. As we have said, the book is an agreeable contribution to that branch of literature which aims at creating sympathy with animals among those who constantly employ them; and in so far as it aims at provoking mercy on their behalf, we gladly welcome it. As professing to dictate the limits of scientific inquiry, however, it is out of place, and would have been better fitted to achieve its purpose had this portion been omitted from its contents.

(a) "Morality: an Essay addressed to Young Men." By Maurice C. Hime, M.A., LL.D.

(a) "Plea for Mercy to Animals." By James Macaulay, M.A., M.D. Edin. Partridge and Co.

**Obituary.**

**DR. JAMES PATERSON, OF GLASGOW.**

To write the obituary notice of a friend, is like conveying a last request from a dying fellow-soldier on the battlefield. The scythe of death has been busily plied in Glasgow during the past few years, and many of the old familiar faces in the profession have disappeared for ever. Dr. James Paterson died at the Bridge of Allan, whither he had gone a few days previously, on Tuesday, the 21st inst. He had been laid aside from the active duties of his large practice for the previous nine months, the phase which his illness assumed being that of an obscure cerebral affection. To the last his intellect was perfectly unimpaired, though he suffered from a peculiar variety of hemiplegia. The son of a medical man, Dr. Paterson entered the medical profession in the year 1834, and like many more who have risen in Glasgow to positions of honour, if not of affluence, he began practice in the east-end of the city, in a comparatively humble way. He there very soon acquired a large connection, becoming well-known as a successful obstetrician. In the year 1841 he became a Fellow of the Faculty of Physicians and Surgeons of Glasgow, under the old regulations, and in the same year was offered and accepted the position of lecturer on midwifery at Anderson's College, then called the Andersonian University. From this position he retired in 1863, being succeeded by the late Dr. James G. Wilson. By his large *clientele*, Dr. Paterson was much respected for his straightforward manliness of character, and his, perhaps, for himself, too pronounced an intolerance of every form of sham, or smallness. He was influenced in an eminent degree by a sterling loyalty to truth. During the earlier part of his University curriculum, he studied with the intention of entering the church, but like many able and conscientious men, he found he was unlikely to submit to the ecclesiastical thralldom, which was then more pronounced in Scotland than it is even now, and he consequently turned his attention to a calling in life in which a *little more* freedom is enjoyed. He was thus possessed of an excellent preliminary education, evidences of which appeared in everything which he published. He was a fluent and effective writer and speaker, and as a lecturer was very popular with his students. Some years ago his name came prominently before the public in connection with the celebrated Pritchard case. He occupied in connection with this case a very delicate position, and it is not too much to say that it was doubtless owing to his shrewdness that the criminal was brought to justice. Dr. Paterson leaves a large family—one in the medical profession in Australia—all occupying honourable positions in their respective professions. It is noteworthy that three of his sons are masters of arts of the University of Glasgow. He faced death, as he faced the world with neither fear nor cringing, but with becoming reverence and resignation. According to his own particular request, he was interred in Janefield Cemetery, Glasgow, his funeral being strictly private.

**DR. SYDNEY MURDOCH, OF DUBLIN.**

With regret we record the death of Dr. Sydney Murdoch in his 41st year, which sad event occurred at his residence, 106 Pembroke Road, Dublin, on the morning of the 13th inst.

From the day upon which he commenced the study of medicine as a student in the Meath Hospital, (where he had the great advantage of having been clinical clerk to the late revered Doctors Stokes and Hudson) up to the day of his demise, he was universally respected by all with whom he came in contact.

Dr. Murdoch was a licentiate of the Royal College of Surgeons, and a member and licentiate of the King and Queen's College of Physicians in Ireland, and for 16 years was one of the medical officers of the Donnybrook Dispensary district. In that capacity especially we would bear testimony to the efficient manner in which he discharged his onerous duties to the sick poor; by whom for his kindness and attention he was deservedly beloved, and for his advice and services highly appreciated.

Owing to delicacy of health of late years, Dr. Murdoch rather avoided private practice, and modestly held aloof

from the professional distinctions which, under other circumstances he would have undoubtedly enjoyed. His unobtrusiveness, charity, kindness, and true friend ship combined, endeared him to a large circle of friends by whom his early death is deeply deplored.

The appointments rendered vacant by the death of Dr. Murdoch, are those of dispensary medical officer and medical officer of health of the Sandymount sub-district.

**University of Oxford.**—The following gentlemen passed the Final Examination for the degree of M.B. :—

Falls, W. C. B.A., M.R.C.S., Merton College and St. George's Hosp. Francis, F. B.A., M.R.C.S., Jesus College, and London Hospital. Gresswell, D.A., B.A., Christ Church and St. Bart Hospital. Jones, Wansborough, B. A., Magdalen Coll. and St. Thomas's Hosp.

**University of Cambridge.**—The following degrees were conferred on June 16th :—

**DOCTORS OF MEDICINE.**—Arthur Thomas Myers, Trinity; Francis Henry Hill Guillemand, Caius.  
**BACHELORS OF MEDICINE.**—Fredk. Henry Hoaitio Mahomed, Caius. Charles, Fillingham Coxwell, Christ's.

**Queens University in Ireland.**—At a meeting of the Senate held on Monday, June 20th, in St. Patrick's Hall, Dublin Castle, the following degrees and diplomas were conferred :—

**Degrees of Doctors in Medicine.**—Henry Harper, of Queen's College, Galway; Michael Jennings, Galway; Walter C. Johnson, Cork; Samuel F. Loughood, Cork; Daniel Lynch, Cork; Joseph R. McDonnell, Galway; Jeremiah McKenna, Cork; James Minniece, Belfast; G. Mitchell, Cork; D. T. Monteath, Belfast; David J. O'Malley, Galway; George H. Powell, Galway and Cork; John Redmond, Belfast; Archibald C. Robinson, Belfast; Robert L. Rutherford, Galway; David M. Saunders, Cork; William D. Sexton, Cork; James Simpson, Belfast; Henry Sinclair, Cork; John M. Trimble, Belfast; Charles H. Wheeler, Belfast.

**Master in Surgery.**—R. Alexander, M.D., Belfast; R. Campbell, M.D., Belfast; W. N. Davies, M.D., Belfast and Galway; J. G. Raghty, M.D., Cork; J. Mullin, M.D., Galway; J. F. L. Mullin, M.D., Galway; J. A. Oakshott, M.D., Cork; J. B. White, M.D., Belfast; J. F. White, M.D., Galway; E. Horan, M.D., Cork; J. Anderson, M.D., Belfast; D. Lynch, Cork; J. McKenna, Cork; C. Minniece, Belfast; G. Mitchell, Cork; G. H. Powell, Galway and Cork; D. M. Saunders, Cork; H. Sinclair, Cork; J. M. Trimble, Belfast; C. H. Wheeler, Belfast.

**Diploma in Midwifery.**—W. M. Davies, M.D., Belfast and Cork; J. A. Oakshott, M.D., Cork; J. B. White, M.D., Belfast; Dr. Lynch, Cork; J. McKenna, Cork; G. H. Powell, Galway and Cork; J. Redmond, Belfast; D. M. Saunders, Cork; H. Sinclair, Cork; J. M. Trimble, Belfast.

**University of Dublin: School of Physic.**—At the Trinity Term Examination for the degree of Bachelor of Medicine, held on June 13, 14, 15, and 16, candidates passed as placed in order of merit :—

Young, Lou's T.  
Full, E. Gordon.  
Lyle, Thomas.  
Woodroffe, Augustus W. } Equal.  
Jencker, Francis J.  
Irwin, James M.  
Donnele, Thomas.  
Nickson, Augustus.  
Grant, Donald St. John.  
Dowse, Thomas J.  
Moore, Reginald H.  
Powell, J. Allan.  
Lewis, Thomas W.  
Macgullan, John W.

Stanton, Thomas.  
Gloster, Charles. } Equal.  
Pope, Henry B.  
O'Hora-Hamilton, Thomas W.  
Jencker, Reginald L.  
Ellott, William S.  
Baldwin, Thomas A. } Equal.  
Stowell, Jonas C.  
Cochrane, Edward.  
Nangle, Edward C.  
Dawson, Henry.  
Lucas, William O.  
Miller, Alfred.  
MacCarthy, William Ff.

**St. Thomas's Hospital.**—The Right Hon. the Earl of Dunraven, K.P., presided Tuesday, June 21, at the Annual Distribution of Prizes to the successful students at this Institution. **PRIZES FOR SUMMER SESSION, 1880.**—*First Year's Students:* F. W. Hatchett, College Prize £15; W. B. Tomson, College Prize £10; C. D. Green, College Prize £5. *Second Year's Students:* R. E. Rouse, College Prize £5. **PRIZES FOR WINTER SESSION, 1880-1.**—*Entrance Science Scholarships:* R. Lawson, Scholarship £100; H. H. Lankester, Scholarship £80. *First Year's Students:* R. Lawson, the Wm. Tite Scholarship £30; H. H. Lankester, College Prize £20; G. A. Carpenter, College Prize £10. *Second Year's Students:* W. B. Tomson, the Musgrave Scholarship 40 gs.; C. D. Green, College Prize £20; F. F. Caigee, College Prize £10. *Third Year's Students:* A. V. Bernays, College Prize £20; A. D. Roe, College Prize £15; W. J. Sheppard, College Prize £10. A Certificate of Honour accompanied the prize to all the foregoing recipients. The Cheselden Medal was awarded to C. W. Haig Brown; the Mead Medal to C. W. Wansbrough Jones; for General Proficiency and Good Conduct and the Treasurer's Gold Medal to W. Wansbrough Jones.

## NOTICES TO CORRESPONDENTS.

DR. T. M. DOLAN'S paper on "The Prophylaxis of Rabies" shall appear during July.

MR. STANNARD.—*California Laurel* is said to be a specific for tooth-ache, and to be a very efficient external application in neuralgia. Either the oil or the fluid extract may be used.

LUDLOW.—You will find the system exposed in a little work called "Medical Men and Manners of the Nineteenth Century."

MR. WILKINSON.—We shall be glad to receive details of the case to which you refer.

## "SICKNESS CAUSED BY PUTRID MEAT."

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—I am glad to see in your "Notes on Current Topics," June 22, that the statements I have made in my "History of Salt" (a) regarding unwholesome meat on which sailors are too often forced to exist, have been corroborated by a letter lately presented to the Michigan Board of Health by Dr. Mulvaney.

I should like to enter fully into this important subject, but do not wish to take up too much space of your valuable Journal.

I am, Sir, yours, &c.

E. MARLETT BODDY.

MR. RIVINGTON will please receive our best thanks.

## THE RECOVERY OF FEES.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—Might I trouble you to answer the two following queries, the first of which is of some moment to others beside myself in the profession: In the early part of last week I was engaged by a respectable mechanic to attend his wife in her confinement, which was expected daily. I accordingly held myself in readiness, when an officious woman, a neighbour it seemed, had offered her services in that way if all was right, and attended her on Saturday last, and the husband called on me last evening, to say that they should not require my services now as his wife had got confined as above stated. *Can I claim my fee legally* in court if I so desired, although I did not attend the said patient? My next question is to ask if an M.B. of the University of London or any other university, is entitled to style himself *Doctor*, as if he were a graduate of some recognised university, or is he entitled to be called *Doctor* only by courtesy? I see all such men put *Doctor* on their door-plates in our town.

I remain, yours very truly,

T. T. P.

[\*] With regard to the first question, our correspondent having been engaged, and held himself in readiness when called on, is clearly entitled to his fee, on account of breach of contract. Beside which it would be well, on public grounds, to teach these uninformed persons that the services of the profession cannot be trifled with impunity. On the second point, an M.B. of a recognised university is frequently styled *Dr.* by courtesy, and the "*Dr.*" on the door-plate is recognised by the public as an implied legal connection with medicine. To be strictly legal, none but those possessed of an M.D. of a recognised university or licensing body can style himself "*Dr.*;" but its employment is now so universal that if a man be on *The Register* objection is not often taken thereto.—ED.]

DR. O. FLANAGAN (Sunderland).—Dr. Brown Séquard recommends in idiopathic epilepsy the following formula, a teaspoonful before each of the three meals, and three tablespoonfuls at bedtime in water:—

℞ Potassii Iodidi;  
Potassii bromidi, ʒj.;  
Ammonii bromidi, ʒss;  
Potassii bicarbonatis, ʒij.;  
Infusi columbe, fʒvj.

The occurrence of sleepiness during the day caused by these remedies can be controlled by giving smaller doses in the day and much larger ones at night. If debilitating effects follow from the use of the bromides, cold baths and a very liberal diet must be resorted to. Dr. Clouston, of the Edinburgh Asylum, has found that the diminution of the fits and all the other good effects of the medicine reach their maximum in adults at 30-grain doses thrice daily. Dr. Crichton Browne has obtained good results from the inhalation of amyl nitrite.

A PROVINCIAL PRACTITIONER.—*Duboisia (Duboisia Myoporoides)*, an Australian plant. The drug is obtained from the leaves. It has properties very like those of atropine; it is said, however, to act more promptly and powerfully, also not to cause so much conjunctival irritation. It is sometimes useful as a substitute for atropia, when that drug is not tolerated; but on the whole it is not so reliable, and is not itself always free from irritating properties on the conjunctiva. Dose about the same as that of atropia.

## VACANCIES.

Charing Cross Hospital Medical School.—Applications for the newly created Chair of Practical Physiology to the Dean before Wednesday, July 13.

Chesterfield Friendly Societies' Medical Aid Association.—Medical Officer. Salary, £185, with midwifery and vaccination fees, with house-rent and taxes free. Applications to the Secretary, Durrant Road, Chesterfield, before July 4.

Great Northern Hospital, Caledonian Road, London, N.—Dental Surgeon. Applications to the Secretary by June 30.

Hospital for Consumption, Brompton.—Assistant Physician. Applications to the Hon. Secs. by July 6.

Kilkenny Union, Tilscom Dispensary.—Medical Officer. Salary, £103, and £20 as Medical Officer of Health. Election, July 18.

(a) "The History of Salt." By E. M. Boddy, F.R.C.S. London: Baillière, Tindall, & Cox. 1881.

Knighton Union.—District Medical Officer and Medical Officer of Health. Joint Salary, £55. Applications to the Clerk to the Guardians by July 7.

Royal College of Surgeons of England.—Pathological Curator. Applications to the Secretary not later than Monday, the 4th of July next.

St. Peter's Hospital for Stone and Urinary Diseases, London.—Assistant Surgeon on the Staff. Applications to the Secretary before July 1. (See Advt.)

Stockton-upon-Tees Hospital.—House Surgeon (non-resident, doubly qualified). Salary, £200 per annum. Applications to the Secretary by August 9.

Victoria Hospital for Children, Chelsea.—Dental Surgeon. Applications to the Secretary before Saturday, July 9.

Wilts Pauper Lunatic Asylum.—Medical Superintendent. Salary, £600 per annum, and furnished apartments. Applications endorsed "Application for Medical Superintendent," to the Clerk to Committee of Visitors, Devises, before July 5.

## APPOINTMENTS.

ANDERSON, W., F.R.C.S., Joint Lecturer on Anatomy at St. Thomas's Hospital.

JACK, J. S., M.B., C.M., Medical Officer to the Rothbury East District of the Rothbury Union.

MAY, B., M.B., F.R.C.S.E., Honorary Surgeon to the Queen's Hospital, Birmingham.

MURSH, T. A. P., M.B.C.S.E., L.R.C.P.L., House Surgeon to the Western-super-Mare Hospital.

READ, M., M.B., B.A., M.R.C.S.E., Junior Resident Medical Officer at the Hospital for Sick Children, Great Ormond Street.

RICHARDSON, R. T., M.R.C.S.E., Assistant Medical Officer to the Leeds Union Infirmary.

RICHARDSON, T. W., M.R.C.S.E., Medical Officer for the Fourth District of the Norwich Union.

ROBERTSON, J., M.D., L.R.C.S.Ed., Medical Officer of Health for the Cokermouth Rural Sanitary District.

SEHMILT, G. R., M.B.C.S.E., Medical Officer of the Third District of the Highworth and Swindon Union.

SMITH, C. E., M.B., M.R.C.S.E., Surgeon to the Eye Infirmary, Wolverhampton.

SPENNER, T. Kent, M.D., M.R.C.S., Physician to the Bath Mineral Water Hospital.

TAYLOR, F. E., M.B.C.S.E., House Surgeon to Charing Cross Hospital.

THOMSON, A., M.B., C.M., Assistant Medical Officer to the Montrose Royal Lunatic Asylum.

WALMSLEY, F. H., M.D., Senior Assistant Medical Officer to the Metropolitan Asylum, Leavenden.

WILLIAMS, W. R., F.R.C.S., L.R.C.P., House Surgeon to St. Peter's Hospital for Stone, &c., London.

WILLS, J. P., M.B., Medical Officer to the Metropolitan Convalescent Institution's new Home at Bexhill, Sussex.

WOODCOCK, R. F., L.R.C.P.L. & M.R.C.S.E., Hon. Medical Officer to the Royal Albert Edward Infirmary and Dispensary, Wigan.

## Births.

BUTLER.—June 18, at 168 Holland Road, Kensington, the wife of W. J. Butler, Surgeon H.M.'s Indian Medical Service (retired), of a daughter.

GUNTHER.—June 21, at Hampton Wick, the wife of Dr. Theodore Gunther, of a son.

OWEN.—June 21, at the Hollies, Shore Road, Hackney, the wife of William Owen, M.B.C.S. Eng., of a son.

PARISH.—June 22, at 14 Steyne, Worthing, the wife of Frank Parish, M.R.C.S., L.R.C.P., of a daughter.

## Marriages.

EMERSON—AINSWORTH.—June 22, at Rivington Church, P. H. Emerson, M.R.C.S., Clare College, Cambridge, to Edith, youngest daughter of the late J. Ainsworth, Esq., of Bolton-le-Moors.

EYRE—BRIGHT.—June 16, at Christchurch, Forest Hill, John Joseph Eyre, L.K.Q.C.P. & L.R.C.S.I., eldest son of Edmond Eyre, Esq., of Shanagolden, Limerick, to Fanny Amy Agnes, eldest daughter of John Meaburn Bright, of Fofest Hill.

## Deaths.

BLOXHAM.—June 8, at Halesowen, Charles William Milnes Bloxham, M.R.C.S.E., aged 59.

CRISP.—June 14, at Aix-les-Bains, Savoy, Walter Crisp, Surgeon-Major, A.M.D., aged 52.

FOLKARD.—June 22, at 18 Blenheim Crescent, Bayswater, W., Henry Folkard, M.B.C.P.Lond., M.R.C.S., aged 55.

LITTLE.—June 22, suddenly, at his residence, Combermore, Lifford, Robert Little, M.B., T.C.D., aged 67.

MUSGRAVE.—May 21, at Bombay, of heat-apoplexy, R. Vernon Musgrave, M.R.C.S.E. P. and O. Co.'s Service, aged 31.

NUTTALL.—May 21, at San Francisco, California, Robert K. Nuttall, M.D., M.D., F.R.C.S.I., youngest son of the late Colonel J. C. Nuttall, J.P. of Tipton, co. Wicklow, aged 68.

STEVENSON.—June 8, at Uporto, Wm. Stevenson, M.D., late of Kingston, Jamaica, aged 52.

## DENTAL HOSPITAL OF LONDON,

MEDICAL SCHOOL.

The DISTRIBUTION OF PHIZES will take place on THURSDAY, JUNE 30th, at Willis's Rooms, King Street, St. James's, at 6 p.m.

Professor OWEN, F.R.S., will preside.

T. FRANCIS KEN UNDERWOOD, Fenz.

Dental Hospital of London, Leicester Square.

## CLINICAL RECORDS.

Pleurisy with endocarditis and pericarditis, autopsy, Dr. Peacock, 6; hypertrophic synovitis of knee-joint, caries of head of knee-joint, abscess of tibia, subsequent suppuration within knee-joint, amputation, rapid recovery. Mr. A. T. Norton, F.R.C.S., 38; case of hydrophobia, W. M. Berry, with remarks by Mr. T. M. Dolan, 49; abscess and caries of head of tibia, result of an injury, trephining, removal of sequestrum, Mr. A. T. Norton, F.R.C.S., 71; case of uterine fibroid, recovery, Dr. Matthews Duncan, 91; suppuration of a goitre during convalescence from typhoid fever, cure of the goitre, M. Huchard, 113; a typical case of mitral constriction following scarlet fever, Dr. Eastace Smith, 136; a case of phthisis, hæmoptysis, recovery, Dr. Burckett, 156; stone in the bladder, lithotomy, recovery from the operation, and departure from the hospital, death subsequently from malignant disease of the bladder, Mr. T. v. n., 181; epithelioma of lower lip, three cases, epithelioma of left temple, anal fissure, extensive elongating phagedæna, amputation through

shoulder, amputation of thigh  
Mr. E. S. O'Grady, 201; pneu-  
mothorax, autopsy, Dr. Thorow-  
good, 224; myxomatous tumour  
springing from lip of os uteri  
in a patient at full term of  
pregnancy, amputation of lip  
of os uteri 4 days before labour  
set in, subsequent inflammation  
of knee-joint, recovery, Dr.  
Lombe Atthill, 249; chronic  
bronchitis for three years,  
unrelieved by usual means;  
rapid cure by punctiform cau-  
terisation of the walls of the  
thorax, Professor Peter, 267;  
case of psoriasis associated  
with osteo-arthritis, cured by  
vegetable diet, Mr. Jas. E.  
Adams, F.R.C.S., 290; abscess  
in thoracic parietes simulating  
empyema, death, post-mortem,  
Dr. Julian Evans, 313; flap  
amputation of thigh, amputa-  
tion of great toe, fistula in ano,  
Mr. Ormsby, 337; case simu-  
lating congenital disease of  
the heart, case of diphtheria of  
fauces, Dr. O. E. Armand  
Semple, 355; cancer of the  
lung, Dr. Birckett, 380; case of  
uremia caused by infraction of  
the kidney, M. Legroux, 401;  
removal of large tumour, bene-  
ficee from contraction of ham-  
string tendons, excision of  
right breast, epithelioma of  
lower lip, Mr. O. msby, 421;  
two cases of acute laryngitis  
with broncho-pneumonia, re-  
covery, Dr. C. E. Armand  
Semple, 444; stricture of the  
Oesophagus, Dr. Charles E.  
Drysdale, 463; case of jpepraved  
appetite, Edward A. Rawson,  
466; necrosis of ungual phalanx  
of thumb, excision of dis-  
eased bone, sarcomatous growth  
from wound, amputation at  
carpo-metacarpal joint, Mr. A.  
T. Norton, 488; case of dis-  
eased knee-joint, with amyloid  
disease and hydrocephalus, am-  
putation, recovery, Mr. M.  
Baker, 508; case of fractured  
base, compression, trephining,  
death, Mr. Traves, 529; acute  
tonsillitis, Dr. C. E. Armand  
Semple, otorrhoea, Dr. Clarke,  
561

**CLINICAL SOCIETY OF LONDON—**  
Hydronephrosis of traumatic  
origin, two cases of myxoedema,  
58; case of chronic vomiting  
in which no food was taken,  
except koumias, gangrene of  
the arm from a poisoned  
wound, 137; small round-celled  
sarcoma of the dura mater  
encroaching on the left tem-  
poro sphenoidal lobe of the  
brain, producing extensive  
softening in its neighbour-  
hood, 138; paralysis due to  
partial disease of the nuclei of  
the motor roots of the fifth  
nerve, 182; quiescent sclirrhous,  
erythema, or herpes iris, 183;  
case of fracture of the lower  
dorsal and upper lumbar ver-  
tebrae, treated with Sayre's  
jacket, recovery, excision of  
the whole tongue by means of  
a small supra-hyoid wound,

## CORRESPONDENCE.

### SUPERANNUATION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In your issue of the 24th Nov. you have a leading article under the above head, in which I am sorry to see you ignore, or omit, the main, and by far the most important, aspect of the case, viz., that superannuation is at present only *permissive*, and dependent on the will of the guardians, and you know it has been shown in many instances that the guardians do not always, nor, perhaps, very often, exercise their discretionary powers in accordance with the strict rules of justice; neither can it be expected that they ever will do so when it is considered how their boards are constituted, and that the majority of them regard the poor rates as a disagreeable tax forced on them.

In support of what I have stated I need scarcely instance the case of the late Dr. Leeper, of Armagh, and others.

At the deputation to the Chief Secretary on the 1st November the same omission is observable in the points brought under review as requiring amendment, except that Dr. Jacob showed (apparently incidentally) "that it is at present open to Poor-law guardians to *superannuate friends*, and to *refuse* a medical officer *whom they may not like*." This, Sir, is the true state of the case in a few words, and herein lies the gist of the argument. I am not sanguine enough to suppose that anything emanating from one occupying so humble a position in the profession as myself can have much influence, and I conjecture (perhaps erroneously) that the Dublin members look on matters with different eyes from country men. Nevertheless, I do trust that there is enough of honest conscience in members of Parliament, and in the main body of our profession, to recognise and act on the truth when it is put plainly before them. Although not personally disinterested, yet it is not altogether from personal motives that I agitate the question. "Homo sum, &c.," and the health and well-being of this country (Dublin included) depends much on the position and duties of medical officers being put on a just basis and rightly appreciated.

The Irish Medical Association admits that the present permissive system of superannuation is a "source of corruption, and unfaithfulness," and I am sure you will agree that it is not the most deserving who get, or are likely to get, much benefit from it.

Yours faithfully,

S. T. HASLETT, M.D.

Donegal, 1st Dec., 1880.

[The leading article referred to was not the emanation of this journal. It was copied from the *Daily Express* as an expression of non-professional opinion, and was inadvertently printed without the name of the journal in which it had appeared. We should have expressed ourselves much more strongly.—Ed. M. P. & C.]

## ROYAL COLLEGE OF SURGEONS' LIBRARY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Perhaps you will kindly allow me to draw attention to a want felt by students reading in this library, and which, though often spoken about, does not seem to meet with any response from those in authority.

There is a small collection of some of the books generally read, all of them old editions, which are bound periodically to keep them together. Very few copies of any, whilst many which are often wanted, are to be had at all, for instance, "Power on the Arteries."

Now, I think that the library committee might at least provide half-a-dozen copies of books of Anatomy, Surgery, and Medicine, and a copy of the latest editions of these and other text-books.

Students become registered pupils (by paying five guineas at the commencement of their studies), chiefly for the reason that they may have entrance to the library to read during the day in the intervals between lectures, &c.; and it is a great inconvenience and loss of time to find that a book is either in use or not to be had at all.

I am Sir, &c., &c.,

A REGISTERED STUDENT.

## THE REGISTRATION ACT OF 1880.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—Having read carefully a book which doubtless has been forwarded to all registrars throughout Ireland entitled "Births and Deaths Registration Acts 1863-80, Ireland," I have come to the conclusion that the Registration Act of 1880 is calculated materially to interfere with the registration of births and deaths in Ireland, and will after a short time be anything but a correct basis for future calculations, and by no means an improvement on the previous Act of 1863. According to the Act 1880, a birth or death can be registered at any time up to one year by the informant (after three months) making a declaration before a magistrate, &c. I will not refer to registration after a year of which there will not be many instances. Now, Sir, let it once go out amongst the people that they have with impunity, when not noticed by the registrar, a year to register a birth or death, and it can be easily understood that before this limit has expired the chances are fifty to one the birth or death is completely forgotten, and consequently, never registered. At present the instances of registration of births after three months are comparatively very few. To carry out the Act of 1880 correctly, it would be necessary for the registrar to go through his district and make inquiries from house to house at least twice a year, otherwise how is he, as stated, to "inform himself carefully of every birth or death that happens within his district." As a rule, the medical man knows very little of the births that take place in his district, except those he attends himself, or is told of accidentally. The same may be said

deaths. If, then, the registrar does not get notice of the birth or death how is he to notice the party to attend at his office? But the best of it is the remuneration remains the same as before, and is likely to become considerably less, though additional writing and trouble is imposed on the registrar by the Act of 1880. I find at page 56, second schedule, that the extra fees, after three months, payable to the registrars, which are here set out and vary from one to five shillings, are to be paid by the "informant or declarant." This is certainly funny! I have been registrar of births and deaths for some years, and have made five shillings on account of births registered after the expiration of three months. In most instances I gave the poor person something for refreshment, for the extra trouble imposed in having to go before the superintendent registrar and walk perhaps a long distance in cases of the kind. In my opinion the limit of registration might (with perhaps some slight modification) have been left as it was with (as in Act 1880) a declaration to be made before a magistrate (when practicable) instead of the superintendent registrar in cases over three months, and the extra fees should most decidedly be paid by the Registrar-General, and not by the "informant or declarant," who in ninety-nine cases out of one hundred (at least in country districts), are paupers. Again, I would ask, will the Registration Act of 1800 facilitate the performance of vaccination before three months.

In conclusion, I will ask your readers to study the Act in question, when they will see that while imposing additional labour and less remuneration, it is neither calculated to instil over-zeal in registrars or serve as a correct basis for future calculations in the statistical and other returns as to the registration of births and deaths in Ireland.

Your obedient servant,

RICHARD AMBROSE O'KELLY,  
Medical Officer Clonhock and Ahascragh Dispensary Districts.

Ahascragh, Ballinasloe,  
Dec. 24th, 1880.

### ARMAGH UNION.

#### LUNACY FEES.

READ an order for payment of £2 to Dr. Anderson.

The Clerk said that it would be a Union charge, and not a divisional one.

Mr. Stronge said that, from his experience as a magistrate, he had always found that the first thing a professional man asks before he gave his evidence, was for his regular fee.

The Clerk said that the fee for doctors in such cases used to be £1, but he found now that they were allowed the maximum, namely, £2. If there was a case in that house they would have to send for Dr. Riggs. The magistrates had no power to call in in such a case any one but the dispensary doctor.

Mr. Campbell said that it was only to give evidence as to the state of the woman that the doctor had been called in.

Mr. Orr thought that it was very unfair in such a case that another doctor should be called in instead of the dispensary doctor.

The Clerk said that the magistrates could call in any any doctor that they pleased, but he must be a dispensary doctor.

Mr. Stronge said that the Board of Guardians had no control over the magistrates in such a matter, and the subject then dropped.

#### THE MEDICINE CONTRACT.

A letter on the matter of the medical contractor not sending the invoice to Dr. Houston, of the Tynan dispensary, with the medicine was received from Mr. Leslie, the contractor, and one enclosed therewith from Dr. Houston in which the latter stated he had no idea of finding fault with him (Mr. Leslie) with the Guardians.

Mr. Gray thought that the clerk should write to the contractor on the matter; and

Mr. Riggs said that he (the clerk) had done that already.

### DROGHEDA UNION.

#### VACCINATION.

THE following was read:—

Local Government Board.

Dublin. 24th November, 1880.

The Local Government Board desire to be informed what steps have been taken to enforce compliance with the requirements of the Compulsory Vaccination Act in the district?

B. BANKS, Secretary.

Mr. Dowdall—How many on the list?

Mr. Marley (R. O.)—Eight or nine; I noticed them all, and they all went; sometimes they have to go eight or nine times before it is successful.

Mr. Dowdall—Then to your knowledge they all attended to the notice?

Relieving Officer.—They all attended.

Dr. Burke—Did you serve regular notices on them?

Relieving Officer—No; I gave them all verbal notice; I have no forms.

Dr. Burke said that it would be advisable that these officers should be supplied with printed forms of notice to serve in all such cases; a verbal message is apt to be treated lightly; in point of fact and law, however, they were not bound to give any notice to these parties; it was simply an act of kindness and consideration on the part of the guardians to give them notice. The medical officer makes a very serious charge—namely, that this neglect in having the Vaccination Act properly carried out arises from the fact that the guardians just read the list of defaulters, and no action whatever is taken on the reports sent in; that in fact they do not see that the orders are carried out; now it appears that in these cases they have been carried out according to the relieving officer's statement.

### LISNASKEA UNION.

#### EMERGENCY MEDICAL ATTENDANCE.

DR. CHARTERS presented an account for £1 1s. for visits to a man named Clinton, who was taken ill and died. It appeared when the man was taken ill at night the house occupier went to Dr. Charters, as he said he heard Dr. Knox (who was acting as *locum tenens*) was not in Lisnaskea at the time, and he did not go first to see was Dr. Knox obtainable, nor had he (the occupier) a visiting ticket. He now sought to get the amount of Dr. Charters' account from the guardians.

Col. Archdall said the previous case of payment to Dr. Charteris when he had attended instead of Dr. Knox was a precedent for this one, and he was afraid that cases like this would become frequent now. Could the guardians legally pay this?

It was resolved to ask the Local Government Board's advice in the matter. Could the guardians pay in such a case?

### WESTPORT GUARDIANS.

#### VACCINATION.

THE Local Government inquired if the guardians had done anything about the defaulters under the Vaccination Act in the Westport district.

The Chairman said—At the time of the passing of the New Vaccination Act this board by perseverance and careful administration of the law brought vaccination in the union almost to perfection. Although not in favour of a compulsory law he was bound to carry out the vaccination law, and so well had the vaccination been carried out that at the time this new law was passed there was only one defaulter in the union. What were the features of the new act? The important ones were—First, that a parent became a defaulter when his child was aged three months instead of six months as heretofore, and

that the new law gave the doctor £1 a day expenses for prosecuting before the magistrates, and 2s. instead of 1s. as the vaccination fee. The guardians fairly apprehended this law would heavily increase their rates and was an inducement for encouragement to prosecutions. (Hear, hear). His (the chairman's) opinion was that the guardians should simply tell the relieving officers to warn the people to attend with their children and they might add that upon a full consideration of the question they did not think it right to do anything further (hear, hear). The fees were large and the expenses for the doctor enormous, and they had great reason to fear this new act would lead to an enormous increase of expenditure and to great abuse (hear, hear).

The Board unanimously concurred in the views of the chairman, and a resolution was accordingly passed.

Resolved, in reply to the letter of the Local Government Board of 22nd inst., relative to defaulters under the Vaccination Act, the guardians desire to state that the lists were referred to the relieving officers to call on the defaulters to come in and comply with the law. The enormous legal expenses, including the fees to medical officers imposed by recent legislation renders it imperative on the guardians to be extremely careful how they adopt a course which will largely help to crush the people of the country by excessive taxation.

## IRISH MEDICAL ASSOCIATION.

### REPORT OF THE PROCEEDINGS OF THE COMMITTEE OF COUNCIL,

*During the Half-year ended 7th December, 1880.*

(Read and adopted at the Meeting of Council held 11th December, 1880.)

DR. J. W. MOORE, Chairman of Council, in the Chair

MR. CHAIRMAN AND GENTLEMEN,—During the past half-year the Committee of Council held twenty-four meetings, and thirty new members were enrolled.

In consequence of the changes which took place amongst the officers of the Association, viz., Dr. Chapman having been promoted to the Presidentship, and Dr. Speedy to the Hon. Secretaryship, as also the resignation of the Assistant-Secretary, the Committee of Council could not conveniently at the usual time, present to you a quarterly report, and therefore did not convene the ordinary quarterly meeting of Council which, if circumstances had permitted, should have been held last September, but one ordinary and two special meetings of the Council (to which reference shall hereafter be made) were held within the half-year.

#### THE NEW REGISTRATION OF BIRTHS AND DEATHS ACT.

The Committee of Council, considering that a full and detailed report upon this measure—explanatory of the action of this Association, and of the changes of special interest to the Registrars which have recently been made by amendment of the law—would be desirable, have deemed it better to submit a special report on the subject as an appendix hereto. Upon the passing of the Bill, a resolution expressing the marked thanks of the Association to Mr. Meldon, M.P., and the Viscount Powerscourt, was adopted, and duly conveyed to them, for their valuable, zealous, and effective services in obtaining the new act.

#### THE MEDICAL CHARITIES BILL.

This Bill was introduced in the House of Commons last Session by Mr. Meldon and Mr. Errington, at the instance of this Association, but it unfortunately was so unfavourably received that it had to be abandoned. The Bill, which was published in full in the Report for quarter ended 31st December, 1879, proposed :—

1. A definition of persons eligible to receive dispensary medical relief.
2. Abolition of the office of warden.

3. New arrangements as to the issue and cancelling of tickets for medical relief.

4. Liability for improper use of tickets.

5. A provision for affording medical relief on loan in doubtful cases.

6. An amendment of the law regarding examination of alleged lunatics.

7. A more equitable scheme of superannuation of medical officers.

8. Better regulations as to contracts for drugs.

9. Examination of drugs, and inspection of pharmacies.

#### DEPUTATION TO THE CHIEF SECRETARY RELATIVE TO SALARIES OF MEDICAL OFFICERS OF HEALTH AND SUPERANNUATION OF POOR-LAW MEDICAL OFFICERS.

Having failed to obtain from the authorities any recognition of the amendment made in the law by the passing of the Public Health Act of 1878 in favour of the medical officers of health whereby the maximal scale of salaries was expunged—an amendment made at the instance of this Association, and solely on account of which the new Act was allowed to pass—the Committee of Council, supported by other members of Council, and by Mr. Meldon, M.P., waited by deputation upon the Right Hon. W. E. Forster, Chief Secretary for Ireland, on the 1st November, and represented to him the unsatisfactory state of the administration of that Act as the natural result of the unjust treatment of the medical officers of health who have not even yet been awarded equitable salaries.

The deputation also brought under the notice of the Chief Secretary the subject of superannuation of Poor-law medical officers. A full report of the proceedings has appeared in the Supplement to the *Medical Press*.

Acting upon the suggestion of the Chief Secretary, the Committee of Council forwarded the following memorial to the Lords Commissioners of Her Majesty's Treasury, viz :—

#### TO THE LORDS COMMISSIONERS OF HER MAJESTY'S TREASURY.

##### *The Memorial of the President and Council of the Irish Medical Association.*

SHEWETH,—That Your Lordships' Memorialists are the Executive of an Association of medical practitioners, including the great majority of the medical practitioners charged with the execution of the sanitary law in Ireland.

That by the Public Health (Ireland) Act of 1874, section 10, the dispensary medical officers of Ireland were, without any option on their part, constituted medical sanitary officers, at such salaries, additional to their previous emoluments, as their sanitary authorities might fix, subject to the sanction of the Local Government Board for Ireland, "Provided, with regard to salaries or additional salaries whereof any portion is to be recouped to any local fund from moneys voted by Parliament, the amount of any new salary, and the proportion between any existing salary and the addition thereto, shall be regulated according to a scale to be approved by the Commissioners of Her Majesty's Treasury."

That despite the protest of the medical sanitary officers against the limitation of their remuneration by any fixed maximal scale, the Local Government Board for Ireland did by letter, dated 14th day of October, 1874, propose to your lordships the adoption of a scale restricting the additional salaries for the sanitary duties of the medical officers to one-fourth the salaries paid to them for medical duties, to which proportion your lordships, by letter dated 11th November, 1874, while expressing the opinion that the proposed remuneration "did not strike my lords as exorbitant," ultimately assented, but "with the understanding that the scale will be applied with due regard to the circumstances of each case.

That, following upon such assent, the Local Government Board for Ireland issued to the sanitary authorities throughout Ireland a circular order that no salary for sanitary duties should exceed such proportion of the salary for medical duties, the effect of which order your lordships'

memorialists submit that merely nominal salaries were allotted in the great majority of instances; in but a few instances salaries exceeding two-thirds of the maximal limit were voted, whilst the maximum was awarded in only a very few isolated instances, the average salary being only about half of the maximum, although the sanitary districts extended over many thousands of acres, and contained populations of several thousands.

Such remuneration, your lordships' memorialists respectfully submit, was far from being equitable payment for performance of the onerous and invidious duties compulsorily imposed.

That by reason of the refusal of adequate remuneration for the arduous duties of the medical sanitary officers, and in consequence of the discouragements under which those duties were discharged, the efficiency of administration of the sanitary law in Ireland declined until its execution came to be, and still continues, altogether unsatisfactory, in proof of which your lordships' memorialists beg to refer your lordships to the "Return of Public Health Salaries and Work in Ireland," No. 351, presented to Parliament on the 12th day of August, 1878, and to the successive Appendices to the Quarterly Reports of the Registrar-General for Ireland for 1875 and following years.

That upon the introduction of the Public Health (Ireland) Amendment Bill in 1877, your lordships' memorialists took immediate steps, on behalf of the medical sanitary officers of Ireland, to cause the limitation of salaries, hereinbefore referred to, to be repealed, and with that object waited, by deputation, upon the then Chief Secretary for Ireland, and in the following year attended the sittings of the Select Committee to which the Bill was referred.

That in consequence of the representations made by Mr. Meldon, M.P., at the instance of your lordships' memorialists, it was eventually agreed by Government that the Bill should be altered so as to abolish the limitation of which your lordships' memorialists complain, and allow each case of remuneration to be decided on its merits; and for this purpose the second paragraph of the 11th Section of the Bill, as it then stood, was altered to read as follows: "Provided that, with regard to salaries or additional salaries, whereof any portion is to be recouped to any local fund from monies voted by Parliament, the amount of any new salary, and the proportion between any existing salary and the addition thereto, shall be approved by the Commissioners of her Majesty's Treasury." In this form the Act passed, and now stands.

Your lordships' memorialists pray the attention of your lordships to the wording of the Section as compared with the Section of the Act of 1874, quoted in the second paragraph of this memorial.

That notwithstanding this alteration of the law, deliberately made by Government at the instance of your lordships' memorialists, the Local Government Board for Ireland did, on the 15th day of August, 1879, issue a circular to sanitary authorities in Ireland, in which it is stated—"The Local Government Board are advised that medical officers of health are not included among the officers of sanitary authorities appointed under the Public Health Act, 1874, and who are referred to in the 280th section of the Public Health Act, 1878, as entitled to continue to hold their several offices and employments on the same terms, and subject to the same conditions, as they would have held them if the Act of 1878 had not been passed. It will therefore be necessary for the sanitary authority to take the subject of the salaries of the medical officers of health into consideration, and to state the amount of additional salary which they think should be paid to each dispensary medical officer within the sanitary district, for the duties imposed upon him as medical officer of health by the Public Health Act, 1878, and the order of the Local Government Board made thereunder."

That quickly following upon the issue of said circular, the Local Government Board did, on the 28th day of

August, 1879, issue to every sanitary authority in Ireland another circular containing the following:—

"The Local Government Board for Ireland have reason to believe that some misapprehension exists as to the purport and effect of that part of their circular-letter of the 15th inst., which relates to the salaries of the medical officers of health, under the 11th section of the Public Health Act, 1878, and as to the information required to be given in the form of return which accompanied their letter of the 15th inst. It appears to be supposed, in some cases, that the additional salaries to be determined by the sanitary authorities and paid to the dispensary medical officers, as 'medical officers of health,' under the 11th section of the Public Health Act, 1878, are to be in addition to the salaries hitherto paid to them under the 10th section of the Act of 1874 as "sanitary officers." "This, however, is *not the case*; the dispensary medical officers held the office of sanitary officer, not by appointment of the sanitary authorities or of the Local Government Board, but they were so constituted directly by the Act of 1874, and the effect of the repeal of that Act, and the simultaneous re-enactment in the Act of 1878 of the same provisions, with merely a change in the title of the officer from "sanitary officer" to "medical officer of health," is that they now hold their offices under the Act of 1878, and it consequently becomes necessary to consider the question of the salary, which, under the 11th section of that Act, is to be in place of, and *not in addition to*, the salary paid under the Act of 1874."

The effect of these circulars was that the great majority of the sanitary authorities not only did not grant any increase on the very inadequate salaries previously awarded to their medical officers of health, but on the contrary sought, in many instances, to reduce those salaries. In a few instances, however, the salaries were increased beyond the extent of the repealed scale, but the Local Government Board declined to sanction the excess; such officers are therefore, notwithstanding the alteration of the law in their favour, compelled to perform their sanitary duties for remuneration now more inadequate than ever.

Your lordships' memorialists most respectfully submit:—

(a.) That the salary of each medical officer of health should be fixed upon the basis of the extent and population of his district, and not upon that of his medical salary, which represents the discharge of duties totally diverse, and in no way comparable with his sanitary functions.

(b.) That the fixing of a very low maximum of salary, which sanitary authorities may not exceed, no matter what the amount of duty required, is calculated to render nugatory the sanitary law by greatly discouraging the medical officers of health in the discharge of their duties.

(c.) That the change of law effected by Government upon the representation of a large class of public officers ought not to be set aside.

Your lordships' memorialists therefore pray that your lordships will be pleased to direct that the salary payable to each medical officer of health in Ireland shall be assessed with regard to the extent of the duty imposed upon him, and free from any limitation whatsoever, in order that the case of each medical officer of health may be fairly dealt with on its merits, in fulfilment of the distinct understanding arrived at previous to the passing of the Public Health (Ireland) Act of 1878 by Mr. Meldon, M.P. (acting at the instance and on behalf of your lordships' memorialists), and the official representatives of her Majesty's Government.

And in order that, in the interests of the community, full effect may be given to the provisions of the Public Health Act, your lordships' memorialists further pray that your lordships will be pleased to direct that the sanitary authorities of Ireland shall be exhorted to award equitable remuneration to the medical officers of health.

JOHN H. CHAPMAN, President.

# IRISH POOR-LAW INTELLIGENCE.

## DUNMANWAY DISPENSARY.

An extraordinary meeting of the committee of management of the Dunmanway Dispensary District was held on Tuesday, the 4th January, 1881, on the requisition of J. Hamilton Bryan, Esq., J.P., Chairman, and John Atkins, Esq., Hon. Sec., to take Dr. S. Holmes' resignation into consideration.

It was unanimously resolved, in accepting Dr. S. Holmes' resignation, the committee desire to express their regret at the cause necessitating his resignation, and the connection existing between them for so many years being now severed, they cannot let this opportunity pass without bearing testimony to the faithful, earnest, and zealous manner in which he discharged his duty in every capacity, while Medical Officer of this District.

That we unanimously recommend Dr. S. Holmes' retiring allowance to the favourable consideration of the Board of Guardians, and that a copy of this resolution be forwarded to Dr. S. Holmes.

## ABUSE OF TICKETS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—On the 7th inst. I got cancelled a ticket for attendance at dispensary, issued by Mr. P. Soraghan (baker) to Biddy Johnston (15), of Mayo, whose father, with whom she lives, is a farmer and also a pensioner, drawing £72 a year as an ex-constable, R.I.C. I send these particulars as I think it was mentioned in one of your numbers that it would be well to keep an account of all cancelled tickets.

I am, &c.,

P. L. M. O.

## LIST OF ENTRIES IN THE REGISTER OF THE BRANCH MEDICAL COUNCIL (IRELAND) FOR THE MONTHS OF NOVEMBER AND DECEMBER. 1880.

### NOVEMBER.

3rd.—Hall, Henry Stocker Wilson; Llandrinio, Montgomeryshire; Lic. 1880 and Lic. Mid. 1880 K. Q. Coll. Phys. Irel. Lic. R. Coll. Surg. Irel. 1880.

5th.—Broomfield, Humphrey John; Rathdowney, Queen's County; Lic. R. Coll. Surg. Irel. 1880.

9th.—Lambkin, Francis Joseph; 36 Haddington Road, Dublin; Lic. K. Q. Coll. Phys. Irel. 1880, Lic. R. Coll. Surg. Irel. 1880.

9th.—McCarthy, Edward Cudmore; Bandon, co. Cork;

Lic. R. Coll. Phys. Edin. 1880, Lic. R. Coll. Surg. Edin. 1880.

9th.—McGeagh, James Paul; 18 Claremont Terrace, Belfast; M.D. 1880 and M.Ch. 1880 Q. Univ. Irel.

9th.—McGeagh, Robert Thomas; 18 Claremont Terrace, Belfast; M.D. 1880 and M.Ch. 1880 Q. Univ. Irel.

11th.—Shore, Robert; Wood Quay, Galway; M.D. Q. Univ. Irel. 1880.

19th.—Forster, Henry John; 32 Cambridge Terrace, Hyde Park, London, W.; Lic. R. Coll. Surg. Irel. 1878.

22nd.—Kennedy, Michael Colville; Dronin Lodge, Ballybanion, co. Kerry; Lic. R. Coll. Surg. Irel. 1880.

23rd.—Furney, Simon Kenny; Butler's Grange, co. Carlow; Lic. R. Coll. Surg. Irel. 1878, Lic. Apoth. Hall Duh. 1879.

24th.—Roulston, Robert John; Beragh, co. Tyrone; M.D. 1880 and M.Ch. 1880 Q. Univ. Irel.

26th.—Nevin, James Loughlin; Carnaff, Dercock, co. Antrim; Lic. R. Coll. Phys. Edin. 1880, Lic. R. Coll. Surg. Edin. 1880.

### MEMORANDUM.

The following name was restored per order of Medical Council, viz.:

Oct. 22nd, 1860.—Hall, John Henry Wynne; 18 Adelbert Terrace, Albert Square, Clapham, London, S.W.; Lic. Fac. Phys. and Surg. Glas. 1860, Lic. R. Coll. Phys. Edin. 1866, Lic. Soc. Apoth. Lond. 1866.

### DECEMBER.

1st.—Magennis, Edward; William Street, Lurgan, co. Armagh; Lic. R. Coll. Phys. Edin. 1880, Lic. R. Coll. Surg. Edin. 1880.

3rd.—Warren, Richard Benson; 9 Great Denmark Street, Dublin; Lic. 1880 and Lic. Mid. 1880 K. Q. Coll. Phys. Irel., Lic. R. Coll. Surg. Irel. 1880.

10th.—Cochrane, Robert; Coleraine, Co. Derry; Lic. 1880 and Lic. Mid. 1880 R. Coll. Surg. Irel.

11th.—Eakin, Samuel; Donaghmayne, Carrickmacross, co. Monaghan; M.D. 1880 and M.Ch. Q. Univ. Irel.

22nd.—Scully, Albert McCarthy; Brownstown, Clonakilty, co. Cork; M.D. 1880 and M.Ch. 1880 Q. Univ. Irel.

23rd.—West, William Augustus; Ardenode, Brannoxtown, Newbridge, co. Kildare; Lic. R. Coll. Surg. Irel. 1879, Lic. 1880 and Lic. Mid. 1880 K. Q. Coll. Phys. Irel.

23rd.—McDermott, Patrick Andrew; 6 St. Alphonsus Road, Drumcondra, co. Dublin; Lic. R. Coll. Surg. Irel. 1880.

24th.—Exham, Frederick William; Monkstown, co. Dublin; Lic. 1880 and Lic. Mid. 1880 K. Q. Coll. Phys. Irel., Lic. R. Coll. Surg. Irel. 1880.

24th.—Nicolls, John Michael; 22 Eccles Street, Dublin; M.B. 1880 and B.Ch. 1880 Q. Univ. Irel.

27th.—Reed, John Stephenson; Slieveroe, co. Monaghan; Lic. R. Coll. Surg. Irel. 1876, Lic. R. Coll. Phys. Edin. 1877.

## MEMORANDUM.

The following names have been erased from the Register of the Branch Medical Council (Ireland) during the month of December, 1880, pursuant to the 14th Section of the Medical Act, no reply having been received to several letters of application, viz.:-

Trenor, Wm. Adams; Belgrave Sq., Rathmines. Dead.  
Garland, Charles; Carrickmacross. Dead.  
Jenkins, Aneurin; Loughor, Glamorganshire. Dead.  
Browne, William; Rondragh, Fahen, co. Derry. Dead.  
Roe, Charles; Cape Coast Castle. Dead.  
James, Henry Godfrey; Beverley, Yorks. Dead.  
Marshall, Joseph, Dromore, co. Tyrone. Dead.  
Alocock, Robert David; Waterford. Dead.  
Dobbin, John; Keady, co. Armagh. Dead.  
Faussett, Wm.; Clontarf, co. Dublin. Dead.  
Sandells, William James; Lisnaskea, co. Fermanagh. Dead.

## IRISH MEDICAL ASSOCIATION.

REPORT OF THE PROCEEDINGS OF THE  
COMMITTEE OF COUNCIL,

*During the Half-year ended 7th December, 1880.*

(Read and adopted at the Meeting of Council held 11th December, 1880.)

*Continued.*

## SUPERANNUATION OF MEDICAL OFFICERS.

During the past session of Parliament the Committee of Council became cognisant of the fact that Dr. Davison, Medical Officer of Crossgar Dispensary District, in the Banbridge Union—who, during more than forty years, had zealously and faithfully discharged his duties, as testified by the committee of management of his dispensary district, and also by the board of guardians of his union—was obliged, in consequence of incapacity, caused by advanced age and failing health, to resign his appointments; and that the board of guardians were about to refuse him any superannuation allowance. The Committee of Council therefore felt called upon to acquaint Mr. Meldon, M.P., with the facts of this instance of grave injustice, it being a serious abuse of the permissive privileges conferred upon the guardians, and requested him to bring the matter under the notice of Parliament. Mr. Meldon, with his usual kindness, accordingly put the following question in the House of Commons, on the 10th day of August, viz.:-

"To ask the Chief Secretary to the Lord Lieutenant of Ireland if it is the case that the Medical Officer of the Crossgar Dispensary District, in the Union of Banbridge, having, after forty years' service, applied for superannuation on the ground of broken-down health, the guardians, at a meeting, passed a resolution 'to record on the minutes their approval of the manner in which the medical officer has filled such office for a period of forty years, but that the guardians cannot add to the rates by granting any retiring allowance.'"

"Whether the passing of such a resolution, under the circumstances, fairly carries out the principle of the Medical Officers' Superannuation Act.

"If the Local Government can or will interfere in the matter, and if the Government will promote or support a measure to make the superannuation of the poor-law medical officers, in proper cases, compulsory on boards of guardians."

To which the following reply was made by the Right Hon. W. E. Forster, Chief Secretary for Ireland, viz.:-

"Sir, the facts, as stated by the hon. and learned gentleman, are true. It is, no doubt, a case of great hardship; but the guardians did not think fit to make the allowance, and the Local Government Board has no power to interfere in the matter. I think I have stated before, in reference to an inquiry as to the superannuation of those officers, that the subject was one which occupied largely

the attention of the Government, and I hope we may be able to deal with it next year."

On the 10th August, Mr. Meldon, M.P., obtained an order of the House of Commons for a return to be made, "giving the names of all medical officers of workhouses and dispensaries in Ireland who, since the passing of the Medical Officers' Superannuation Act, 32 and 33 Vic., c. 50, have resigned their offices, and applied to their boards of guardians for superannuation allowances under that Act, with the causes for such resignation, the ages, and length of service as poor law medical officers of each person at date of resignation; the result of such application to the guardians, and the reason, if any, given by the said guardians for refusing the application."

It is to be hoped that this return will have good effect.

A deputation from a large and influential meeting, lately held in Dublin, of the Irish union officers, waited on the Committee of Council to confer with them as to the possibility of agreeing to a general scheme of superannuation for all union officers, including all medical officers in the Poor-law service; and subsequently several other conferences were held between representatives of the union officers and of the Committee of Council, which resulted in the drafting of a Bill for further consideration.

The Committee of Council hope the time has nearly arrived at which it will be possible to have the question of superannuation of Poor-law medical officers considered by Parliament, the many recent instances of grave abuse of the present system having, in a great measure, convinced legislators that that system is so capriciously administered as to render it inequitable.

It was undoubtedly intended by the legislature that the laws now in force should be administered with fairness, and that all boards of guardians should deal considerately, as it is admitted a few boards have, with retired medical officers who had served the public faithfully; the permissive power of those laws was certainly not given to boards of guardians, with the object of permitting them to refuse an equitable retiring allowance in any case.

The question now is, what amendment of the law will be satisfactory, just, and feasible, which should be put forward by this Association.

A system of compulsory superannuation allowance, giving, as a matter of right, two-thirds of all salaries and emoluments at the time of resignation, in consequence of incapacity caused by old age or ill-health, appears to be what is universally expected by all medical officers; for the present system admits of that (with certain recently made restrictions to be hereafter referred to), if all boards of guardians exercised their discretionary powers with uniform fairness. The Committee of Council, however, consider that all medical officers should be entitled to claim superannuation, as of right, even though they may not have continued to hold office until incapable of discharging their duties with efficiency. In all public departments the period of service of the officials entitles them to compensation or pensions upon earlier retirement; and the Committee of Council deem it but reasonable that that principle should be extended to the medical officers of the Poor-law service.

It has been suggested that the Civil Service system of compulsory superannuation should be sought for medical officers, and probably it could be obtained, even with the emoluments of those officers being admitted into the computation; but that system, which allows only one-sixtieth of the official income, at the date of retirement, for each year served—the maximum being two-thirds—would not admit of justice to any but those who had served at least forty years, as it would require that length of service to entitle a medical officer, upon retirement, to two-thirds of his salary and emoluments. In the case of one, under that system, who had served but ten years, he would be entitled to only one-sixth, one who had served twenty

years only *one-third*, and one who had served thirty years only *one-half*.

The Civil Service scheme may therefore be put aside as not affording a satisfactory result; but as comparison with that system will inevitably be made, and great opposition be offered to a higher rate being allowed to medical officers of the Poor-law service, the Committee of Council would contrast those services thus:—Gentlemen enter the Civil Service usually fresh from school, as mere youths; they have no necessary expenses of office, and need not be householders; they have fixed hours of daily work, exclusive of Sundays, and have a period of holidays annually, without stoppage of salary; they have yearly increasing salaries; they work in salubrious offices, and, if obliged to travel, do so free of expense; marriage is not essential to their success; their work does not tend to shorten life; they usually do not retire until they have served forty years, and then are comparatively fresh; have not, when ill, to provide a substitute; when they retire they are usually in receipt of good salaries, and their pensions are consequently large. Medical officers cannot enter the Poor-law service until at least twenty-three years of age, but seldom enter it so early in life, and have to incur heavy expenses in obtaining their professional education and qualifications. Medical officers must be householders, and must keep horses and extra servants, if not carriages; their hours of duty are unlimited, not confined to week days, nor even to day; they must work at all times, and risk their lives and health by exposure to inclemency of weather when hurriedly called up out of bed at any hour of the night; they have no holidays, unless at their own expense; seldom get any increase of salary, and never to any appreciable amount; must work in the midst of infection, fraught with danger to themselves and their families, and in the most unhealthy places; early marriage is almost an essential; their work, more than that of any class, tends to shorten life, and often renders it necessary for them to retire earlier, the vast majority dying before anything like forty years' service has been given, and usually utterly worn out at an early age. When they retire, their official incomes are so small that even the maximum pension of two-thirds is but a trifle, and hardly sufficient to provide the necessaries of life, though usually the only means of their subsistence. If the maximum were granted in all cases, the total would not be a very large sum, as but few long survive retirement. When ill, a medical officer has to find a substitute to perform his duties, and frequently at his own expense.

The young gentleman who enters upon the study of medicine, and ultimately becomes a Poor-law medical officer, while having to bear considerable expense in the acquirement of full professional qualifications, can, of course, during that period, have neither salary nor service entitling him to superannuation; whilst the young gentleman who enters the Civil Service does so without expense, and comes under salary at once, and his service from that moment counts when his pension is being computed.

The medical officer is, therefore, necessarily placed at the double disadvantage of several years' later start, and several years' earlier retirement, owing to the very nature of his work.

These are substantial reasons why medical officers of the Poor-law Service are justly entitled to a higher scale of retiring allowances than Civil servants.

The Committee of Council conceive that the following should be the principle of the measure which should be adopted by this association for proposal to Parliament, viz.:—

1. That a superannuation allowance of two-thirds of the salary and emoluments should be claimable as a matter of right, upon retirement, by all medical officers of the Poor-law Service who have served forty years, or who have become incapable of performing their duties with efficiency by reason of old age (such age being not

less than sixty years), or permanent infirmity of mind or body.

2. That reasonable compensation or a retiring allowance, proportionate to the length of service, should be claimable, as a matter of right, by all medical officers who do not come under the above description.

The Committee of Council consider it advisable that a special general meeting of the association should be convened at an early date to consider this important subject.

#### ASSESSMENT OF SUPERANNUATION ALLOWANCES.

In the last Annual Report, reference was made to the fact that the Local Government Board had made a new ruling with regard to the assessment of superannuation allowances, whereby the salary as medical officer of health, and the fees received for the examination of dangerous lunatics, were excluded from the sources of income upon which the retiring allowances of dispensary medical officers are computed.

The new ruling presses very hardly on the medical officers, several of whom have already suffered in consequence; and although it is at variance with the course observed for many years by the Local Government Board, and is illegal, in the opinion of Mr. Purcell, Q.C., to whom a case was submitted on behalf of this Council, the Local Government Board have positively declined to reconsider their decision, or to yield to the several requests made by the Committee of Council to have the question submitted for the opinion of the law officers of the Crown.

#### MEDICAL REFORM BILLS.

The subject of medical reform received the attention of the Committee of Council who, in view of the near approach of the Session of Parliament, considered it very desirable that an effort should be made to arrive at a general agreement amongst medical reformers upon a single Bill which would fully represent the views of the profession. It was therefore proposed by the Committee of Council that a conference of those who took an active part in putting forward legislative measures should be held in London; with this object, and the suggestion having been accepted with much cordiality by the representatives of the Medical Reform Committee of the British Medical Association, the Medical Alliance Association, by the proprietors of the *Lancet*, and by other influential members of the profession, a conference was held in London at which this Association was represented by Dr. A. H. Jacob.

At that conference the various Bills which were before Parliament in last session were considered, and a series of resolutions adopted, as the basis of a Bill to be introduced as early as possible after the assembly of Parliament, which resolutions are entirely in conformity with the policy of this Association, as already expressed.

The profession may be congratulated upon the unanimity of opinion which exists within its ranks upon these important principles, and upon the zeal with which medical reform is now being pressed forward, and the Committee of Council will not cease their best efforts to advance a cause so important to the well-being of the profession.

#### VACANCY ON THE GENERAL MEDICAL COUNCIL.

Owing to the deeply deplored death of Dr. Alfred Hudson, Crown Representative for Ireland on the General Medical Council, a vacancy in that body has occurred; and the Committee of Council, considering that an opportunity was thus afforded of putting forward the claims of the profession in Ireland to be directly represented in the General Medical Council, forwarded to the Lord President of the Privy Council a memorial praying that the vacant seat may be conferred upon one capable of adequately representing, as directly as possible, the profession at large in Ireland: direct representation of the profession being one of the points of medical reform to which this Association is pledged.

AMENDMENT OF VACCINATION ACTS.

Late in the last Session of Parliament a Bill was introduced in the House of Commons by Mr. Dodson, M.P., to abolish cumulative penalties for default of vaccination, and the Committee of Council, being convinced that the Bill, if passed, would have a disastrous effect upon the public health, though probably not affect medical interests appreciably, forwarded to Parliament a strong petition against the proposed alteration of the law, whereby vaccination would practically cease to be compulsory.

Owing to Mr. Dodson having lost his seat the Bill was not proceeded with, but should it again be brought forward, the Committee of Council consider it should meet with all the opposition which this Association is capable of effecting.

FEES FOR RE-VACCINATION.

A dispensary medical officer recently sent in his account for successful vaccinations and re-vaccinations, duly recommended by the Committee of Management, to his Boards of Guardians; the latter, however, questioned the propriety of paying for re-vaccinations not certified to have been successful, and appealed for information to the Local Government Board, who advised them to the effect that re-vaccinations should not be paid for unless certified to have been successful. But that advice is so evidently at variance with the provisions of the law that the Committee of Council requested and obtained from the medical officer full information regarding the question, with power to act for him in the recovery of his fees. Whereupon a letter was forwarded to the guardians explaining the provisions of the law, and requesting early payment of the account; but as the guardians naturally prefer to act upon the advice of the Local Government Board rather than render themselves liable to be surcharged by the auditor, it has become necessary to sue them; and accordingly instructions have just been given to a solicitor to take legal proceedings against the guardians at the expense of this Association.

Reference to the 6th section of the Vaccination Amendment (Ireland) Act of 1879, and to the previous Acts, will show that it is not provided that any result or report whatever, regarding cases of re-vaccination, shall be made by a dispensary medical officer, whose duty it simply is to furnish to the guardians for payment, an account of the number of his cases of re-vaccination.

With reference to the form of account of successful vaccinations (Form H) required to be furnished to the Dispensary Committee and Board of Guardians, the Committee of Council observe that in many Unions the forms in use go further than the provisions of the law, and require the medical officer to certify in reference to the persons successfully vaccinated the following, viz., "all of whom are resident in the district." At no time, however, was such law in force in Ireland, nor is it so now. The Acts of Parliament require only that the operation of vaccination or re-vaccination shall have been performed within the dispensary district irrespective of the place of residence of the person. The words, "all of whom are resident," should therefore be expunged from "Form H."

COMPULSORY NOTIFICATION OF INFECTIOUS DISEASES.

This important subject was brought under the notice of the Committee of Council by Dr. George F. Duffey, Hon. Sec. to the Dublin branch of the British Medical Association, and Dr. J. W. Moore, Chairman of this Council. Dr. Duffey requested "the assistance and co-operation of the Irish Medical Association in the endeavour to secure for Dublin the advantages of a system of compulsory notification and registration of infectious diseases," but did not suggest any details. A special meeting of the Council was held on the 27th day of July last, when the following resolutions were adopted, viz. :—

1. That this Association fully recognises the advantage

of an efficient system of early and compulsory notification, and subsequent registration of infective diseases.

2. That, as regards notification of infectious diseases, the duty of the medical attendant shall consist alone in his informing the head of the family, or the occupier of the infected house, what the nature of the disease is—to the best of his knowledge and belief—and that it is infectious.—Amendment—Proposed by Dr. Duffey, and seconded by Dr. Tagert, to add in resolution 2 the words, "in writing," after the word "informing," on being put to the meeting was declared lost.

3. That the duty of notifying the presence of infection to the sanitary authority shall devolve solely upon the head of the family or the occupier of the infected house.

4. That in case of the illness of a person who has not been attended by any medical practitioner, it shall be incumbent on the head of the family or occupier of the house to notify to the sanitary authority the presence of infective disease in his house as soon as he becomes aware of its nature; if, in doubt, to obtain the opinion of a duly registered medical practitioner thereupon.

5. That, as regards the registration of infective diseases, the Association is emphatically of opinion that the duty of such registration should not be compulsorily imposed upon the registrars of births and deaths.

6. That in the case of large urban districts, it seems desirable that the registration should be effected by means of a special organisation in connection with the General Register Office.

7. That for every case of infective disease registered by a duly registered medical practitioner, a fee of not less than half-a-crown shall be paid to said medical practitioner.

(To be continued)

THE ACTION OF MAGNESIA SALTS ON THE CIRCULATION.

DR. LAFFARGUE (*La Presse Medicale Belge*) has been making experiments on dogs and rabbits by injecting into the crural vein solutions of magnesia salts. He has come to the following conclusions:—All the salts of magnesia arrest the action of the heart, or slow its movements; at the same time the arterial pressure is lowered. This is the consequence of an action on the bulbous nerve centres, and, secondly, on the intracardiac nerve centres. On cutting the vagus, the cardiac movements reappear.

The magnesia salts can act on the cardiac nerves, suspenders of the respiration inducing their action on the endocardium. They thus produce arrest of the respiration by a mechanism recognised by Vulpian (respiratory syncope). This phenomenon is easily remarked when, injection having been made by the jugular vein, the solution passes directly into the ventricular cavity.

By the same method, a comparative study was made of the salts of sodium, which are antagonistic to those of magnesium. They accelerate the movements of the heart, at the same time increasing its force. Injection of sodium salts simultaneously with those of magnesium neutralises the effect of the latter. These experiments show practically that we should avoid the administration of magnesia salts in persons threatened with syncope or asystolia, and that soda salts should not be employed when there is threatening of congestion or hæmorrhage.

DR. CHARLES EARL, convicted of malpractice, which resulted fatally, was sentenced, in Chicago, recently, to five years' imprisonment in the penitentiary.

# IRISH POOR-LAW INTELLIGENCE.

## IRISH MEDICAL ASSOCIATION.

### REPORT OF THE PROCEEDINGS OF THE COMMITTEE OF COUNCIL,

*During the Half-year ended 7th December, 1880.*

(Read and adopted at the Meeting of Council held 11th  
December, 1880.)

*Continued.*

THE Dublin branch of the British Medical Association lately waited upon the Right Hon. the Lord Mayor of Dublin, by deputation, which was numerously attended and supported by the Presidents of the College of Physicians, College of Surgeons, and this Association, the Registrar-General, the Chairman of your Council, and other gentlemen holding high positions in the profession, when views similar to those expressed in the above resolutions were put forward by the deputation, in the hope that the Lord Mayor would exercise his influence towards obtaining for Dublin a special Act of Parliament which would enforce compulsory notification of infectious diseases in the manner above indicated. The Lord Mayor, however, thought it would be better to endeavour to pass a permissive measure, applicable to all Ireland, and some modifications of the request of the deputation were suggested.

Subsequently the Lord Mayor, by public notice, convened those interested in the question to discuss its merits, and, on that occasion, Dr. J. W. Moore, Chairman of Council, read the resolutions adopted by this Council, further than which this Association has not attempted to go.

It appears, too, that a deputation from the Lord Mayor and Corporation of Dublin, within the past few days, waited upon the Chief Secretary for Ireland, and urged that the duty of notifying the occurrence of infectious diseases to the sanitary authority should be compulsorily imposed upon medical practitioners—a proposition which has not, at least as yet, met with the sanction of this Association.

#### CANCELLING OF TICKETS AND RECOVERY OF FEES.

A case has recently come under the notice of the Committee of Council in which a dispensary medical officer got cancelled an improperly issued ticket for dispensary medical attendance at the patient's residence, and afterwards successfully sued the patient for £1 19s. 11d. at Petty Sessions. The amount of the fee is thus explained: the medical officer was entitled to two guineas, but as a sum of two pounds is beyond the limit recover-

able at Petty Sessions, the medical officer thought it would simplify matters to claim only the above-mentioned amount.

#### PRISON SURGEONS.

Notwithstanding the instances and precedents cited in the last Annual Report of payment of fees to medical officers of prisons for giving evidence and making autopsies at coroners' inquests, another case of refusal, on the part of a coroner, to pay a prison surgeon the fees to which he was legally entitled for such services has come under notice, in which the coroner's view was entirely supported by the Under-Secretary.

The Committee of Council thereupon addressed the Under-Secretary by letter, informing him of the error into which he had fallen, and expressing a hope that no further attempt would be made to deprive those officers of the fees, prescribed by law, to which they were unquestionably entitled.

#### MEDICAL OFFICERS OF DISTRICT ASYLUMS.

The unsatisfactory arrangements relating to retiring allowances of medical officers of district lunatic asylums were, by private letter, cursorily brought under the notice of the late Council immediately before the last annual meeting was held; and the Committee of Council took the earliest opportunity of making inquiries with regard to the subject, but have to report that they received no response whatever from any person who could afford the required information; consequently the Committee of Council can take no further steps in the matter until the necessary particulars are furnished to them.

#### INQUIRY AT THE FEVER HOSPITAL, CORK.

An inquiry having been held to investigate certain charges made against a physician to the Cork Fever Hospital, and the decisions arrived at appearing to the Committee of Council to involve the independence of a physician in the conscientious discharge of his duties towards his patient, a special meeting of the Council was convened on 5th Oct., when the following resolution was accepted:—

**RESOLVED,**—That the Council of the Irish Medical Association, having regard to the facts disclosed in the recent inquiries respecting occurrences at the Cork Fever Hospital, and being of opinion that Dr. Jones acted conscientiously, within the best of his judgment as a physician, and in complete accordance with professional propriety, hereby expresses its sympathy with him in regard to the charges made against him.

That this Council, furthermore, in vindication of the freedom of action of a medical attendant responsible for

the life and health of his patient, cannot recognise the competency of any non-medical tribunal to pass judgment on a question purely of medical science, nor does this Council consider that any physician should be held responsible for results, so long as due skill and care have been devoted by him to the treatment of the patient entrusted to him.

That a copy of this resolution be forwarded to Dr. Jones, and to the editors of the weekly medical journals.

QUARTERLY DINNERS.

As an inducement to members of this Council who reside in the country to attend the quarterly meetings, as well as to afford greater opportunity for discussion of subjects of interest to them, the Committee of Council deem it desirable that the members of Council should be requested to dine together in an informal and not very expensive way on the day of meetings, each to have the privilege of inviting, as his guest, any member of the Association, or any other gentleman, not in the profession, whom he may be permitted, after application to the Hon. Secretary, to invite. The first of these dinners will take place to-day at the Shelbourne Hotel, and the movement, so far, appears to have met with general approval.

NEW ASSISTANT SECRETARY.

Dr. Spencer, having left Dublin, resigned his office as Assistant-Secretary to this Association, and the Committee of Council, having advertised for candidates for the vacant office, have appointed Mr. Thomas Gick to be Assistant-Secretary.

OBITUARY.

The Committee of Council have, with deep regret, to record the deaths of Dr. Hudson, of Dublin, who was lately a Vice-President of this Association; and of Dr. Faussett, of Clontarf, who for many years was a member of this Council.

APPENDIX.

*Report on the Births and Deaths Registration (Ireland) Act, 1880.*

THE attention of the Council of the Irish Medical Association has, during several years been directed to the subject of amendment of the Irish Registration of Births and Deaths Act of 1863. In 1874 the Council drew up a Bill, with the above object, but failed to get it brought under the notice of the Legislature until the Session 1876, when their Bill, having been presented to the House of Lords by the right hon. the Earl of Donoughmore, was read a first time, and referred to the several State departments interested; the departmental reports were favourable, and the principle of the measure was adopted by the Government. The Bill, however, owing to the then state of obstruction to public business, had to be withheld until a convenient time.

The Council, nevertheless, continued year after year, to press for amendment of the law, and to urge the Govern-

ment to take up the measure, but did not succeed in getting the Bill re-introduced until last session when, owing to the change of Government, the Council felt released; and, having determined that the Bill should, without further delay, be introduced as a private measure, confided it to the care of Mr. Meldon, M.P., to bring forward in the House of Commons. Mr. Meldon cheerfully undertook charge of the Bill, and owing to his good judgment and great ability, the various stages of its consideration were reached and passed, though not without considerable difficulty and opposition. Upon its second reading, in June last, the Bill was referred to a Select Committee of the House, with Mr. Meldon as chairman, and Dr. Chapman, President of the Association, at the request of the Council, and at the expense of the Association, went to London to assist its progress. At the first sitting of the Select Committee, almost all the minor details of the Bill were agreed to, consideration of the more important ones being deferred, owing to a matter popularly known as "the Bradlaugh incident," there was intense excitement in the House of Commons upon the second and last day the Select Committee sat, in consequence of which the meeting was not well attended by its members. The second meeting was attended almost solely by members firmly opposed to the concession of fees or advantages to the medical profession, and although the utmost exertion was made to bring up members more friendly disposed it was found impossible to procure their attendance: under these circumstances it cannot be a matter of surprise that the Irish registrars were refused the proposed extra fees for the first twenty entries made in each quarter, which are at present, and have, for many years, been given to the English registrars, as well as almost every other fee the Select Committee could strike out.

When the Bill had been disposed of by the Select Committee, the Council anxiously considered whether it should be allowed to lapse, but, inasmuch as there was no reasonable prospect of obtaining a more satisfactory amendment of the law, and very little likelihood of the subject being taken up again by Parliament probably for several years, it was agreed that—as the Bill, in its then condition, was a decided improvement on the existing law, and afforded greater facilities to the public and the registrars—it should be passed, if possible, and notwithstanding very serious opposition at every stage, the measure was at length safely piloted through the House of Commons; great tact and energy having been displayed at each successive stage by Mr. Meldon, to whom the Irish Medical Association and the medical profession at large are so deeply indebted for many valuable services in their behalf.

The charge of the Bill in the House of Lords was entrusted to the right hon. the Viscount Powerscourt, and to his lordship the Association is also deeply indebted for his kind and valuable services.

When the Bill was at the "Committee" and "third reading" stages in the House of Commons, as well as at its "first reading" stage in the Upper House, every possible attempt was made to have the claim, providing payment of extra fees for the first twenty entries made in each quarter, reinserted; but as it was found that any alteration whatever would imperil the passing of the Bill, and that the House of Lords could not deal with monetary matters, and further that had any amendment been suggested by the House of Lords, the Bill would inevitably have been lost; all further attempts to obtain the desired modifications in the law, not as yet conceded, had to be abandoned, and the measure being accepted by the Council as an instalment of justice, was allowed to pass unopposed. On the day of August it received the Royal assent, and its provisions came into operation on the first day of January, 1881.

The following are the chief changes made in the law which affect the interests of the registrars, viz. :—

*Registration of Births.*—Sec. 1 provides that certain specified persons shall, within forty-two days, give to the registrar information of the particulars required to be registered, and, in the presence of the registrar, sign the re-

gister—the notice required by the old Act to be given within twenty-one days is repealed—the old Act provided that births should be registered at any time within three months; the new Act requires registry within forty-two days.

Sec. 2 provides that notice shall be sent by the registrar after forty-two days, in case of a birth not having been registered, requiring the registry to be made within seven days of receipt of the notice, and before the child is three months old.

Sec. 3 provides that registry for births of “foundlings” shall take place within seven days; the old Act required notice to be given forth, and registry within three months—under the old Act “the person first having charge of the child” was the only person required to give the necessary information to the registrar; under the new Act that duty devolves upon any person finding, and any person in whose charge the child may be placed.

Sec. 4 repeats the provision of the old Act, that registrars shall ascertain and register births, within three months of their occurrence, without fee or reward from the informant.

Sec. 5 extends the period for registry of births, not registered within three months of their occurrence, to twelve months (instead of six months as provided by the old Act), and provides that, in such cases, the informant shall produce to the registrar a solemn declaration (in prescribed form) made before a justice of the peace, whereupon, and upon payment by the informant of a fee of two shillings and sixpence to the registrar, the birth is to be registered, and the declaration to be forwarded to the superintendent-registrar by the registrar, with his quarterly returns; thus the registrar, in such cases, is relieved of the trouble and inconvenience entailed upon him by the 32nd section of the old Act, which required him and the informant to attend at the superintendent-registrar's office.

Sec. 5 also provides for registry of births after twelve months; the registrar-general gives written authority. For registry after twelve months the registrar is entitled to a fee of five shillings from the informant.

Sec. 6 provides that in the case of a qualified informant removing from the district in which a birth occurred, such person may, upon payment of two shillings to the registrar for the district in which he then resides, give to him the required information in the form of a declaration, and that registrar shall forward the declaration to the registrar for the district in which the birth occurred, who shall, forthwith, register the particulars, stating, in the informant's column of the entry, that the information was obtained from a declaration, and the registrar shall forward the declaration to the superintendent-registrar, with the quarterly returns.

Sec. 7 provides that in registering the birth of an illegitimate child, the name of the putative father shall not be registered, unless at the joint request of the mother and of the person acknowledging himself to be the father, both of whom shall sign the register.

Sec. 8 provides for registration of name given to a child, either in baptism or by the parents, within twelve months after registry of the birth, upon payment of one shilling to the registrar or superintendent-registrar, who has custody of the register containing the entry—the said registrar or superintendent-registrar having registered the name, and having certified the fact on the certificate, shall, forthwith, send it to the registrar-general, who shall, if the birth, has been included in a quarterly return, add the name to the certified copy in his office, without requiring a complete certified copy as previously required on form “S.”

*Registration of Deaths.*—Sec. 10 (*verbatim*)—“When a person dies in a house, after the commencement of this Act, it shall be the duty of the nearest relatives of the deceased, present at the death, or in attendance during the last illness of the deceased, and, in default of such relatives, of every other relative (by marriage), of the deceased dwelling or being in the same district as the deceased; and, in default of such relatives, of each person present at the

death, and of the occupier of the house in which, to his knowledge, the death took place; and in default of the persons, hereinbefore in this section mentioned, of each inmate of such house, and of the person causing the body of the deceased person to be buried, to give, to the best of his knowledge and belief, to the registrar, within the *five days* next following the day of such death, information of the particulars required to be registered concerning such death, and, in the presence of the registrar, to sign the register.”

Henceforth deaths are required to be registered within five days of their occurrence.

Sec. 12 provides that if a person required to give information concerning any death sends to the registrar a written notice of the occurrence along with the medical certificate, the time for registry of the death may be extended to within fourteen days.

Sec. 13 provides that, in default of registration of a death within fourteen days, the registrar may, by a seven days' written notice, require a qualified informant to attend for the purpose of registration any time within twelve months.

Sec. 15 provides that after the expiration of twelve months a death must not be registered unless upon the written authority of the registrar-general—for registry after twelve months the registrar is entitled to a fee of five shillings from the informant.

Sec. 16 requires the coroner to send, within five days, his certificate, giving information as to a death which has been the subject of an inquest.

*Burials.*—Sec. 17 provides that a coroner, upon holding an inquest, but not otherwise, may authorise burial of the dead body before the death has been registered—this section also requires the registrar to give, without fee or reward, a brief certificate, when demanded, stating that a death has been registered, or that he has received proper notice under Sec. 12; and enacts that “every such order of the coroner and certificate of the registrar shall be delivered to the person who buries or performs any funeral or religious service for the burial of the body of deceased; and any person to whom such order or certificate was given, by the coroner or registrar, who fails so to deliver or cause to be delivered the same, shall be liable to a penalty not exceeding forty shillings. This section further provides that the person who buries or performs any funeral service without having received such order or certificate shall, within seven days after the burial, give written notice to the registrar or registrar-general under penalty not exceeding ten pounds; such notice, however, may be given in the returns made by the officers of burial boards or cemeteries under the 191st Section of the Public Health (Ireland) Act, 1878.

Sec. 18 provides against interment of the body of a deceased child (born alive) as if it were still-born—in the case of young infants such misrepresentation might be made to avoid the trouble of registry. The body of a still-born child is not to be buried until (a) “a written certificate that such child was not born alive, signed by a registered medical practitioner who was in attendance at the birth or has examined the body of such child; or (b) a declaration signed in the presence of the person giving permission for such burial by some person who would, if the child had been born alive, have been required by this Act to give information concerning the birth, or by the person to whom such permission is given, to the effect that no registered medical practitioner was present at the birth, or that his certificate cannot be obtained, and that the child was not born alive; or (c) if there has been an inquest an order of the Coroner” has been presented to the person who has control over, or who ordinarily buries bodies in any burial ground, under penalty not exceeding ten pounds.

Sec. 19 provides that in case of two or more dead bodies being in one coffin notice shall be procured by the person who buries, and by him shall be forwarded, within five days, to the registrar under penalty not exceeding ten pounds, stating the following particulars:

(a) if the body be the body of a deceased person, the name, sex, and place of abode of the said deceased person; (b) if the body has been found exposed, and the name and place of abode are unknown, the fact of the body having been so found, and of the said particulars being unknown, and (c) if the body be that of a deceased child without a name, or a still-born child; the name and place of abode of the father, or if it is illegitimate, of the mother of such child."

*Certificate of cause of death.*—Sec. 20 requires a registered medical practitioner, who has attended a dead person during his or her last illness, to sign and give to some qualified informant a certificate, stating to the best of his knowledge and belief the cause of death—under the old Act such certificates were directed to be delivered to the registrar. A person to whom a medical certificate is given, in pursuance of this section, who fails to deliver it or have it delivered, within five days of its receipt, to the registrar, is liable to a penalty not exceeding forty shillings.

*Assistant Registrars.*—Sec. 21 requires each registrar to appoint an assistant registrar, with power to act for him at all times, but subject to his control, and also subject to all the penalties declared concerning registrars. The assistant registrar to hold office only during the pleasure of the registrar and registrar-general. Under the old act the deputy-registrar could act only during the illness or unavoidable absence of the registrar.

Sec. 24 requires a registrar, upon demand made at the time of registry by the person giving information, concerning a birth to give to such person a short certificate that the birth has been registered—the fee for which is threepence.

(To be continued.)

#### KILDARE COUNTY INFIRMARY.

APPLICATION was made for the payment of £500 to the treasurer of Kildare Infirmary for the support and maintenance of that institution; also for the sum of £42 to surgeon of same, as a half year's salary.

Mr. Malone did not see why the cesspayers in his district should have to bear part of the burden for the support and maintenance of the Kildare Infirmary, seeing they had never derived any advantage from it, there being no admittances from his side of the county. He did not object to Dr. Chaplin's salary.

Dr. Chaplin said that many patients had come to the infirmary from Mr. Malone's district, although Mr. Malone might not have heard about them.

Mr. Malone thought they were paying rates enough towards the support of that poorhouse infirmary in Naas.

Mr. Byrne said a great many who would not go into the workhouse hospital would go into the infirmary in Kildare.

Mr. T. Cooke Trench said there were a great many small cesspayers in the county who would not like to go into the poorhouse, but to whom the infirmary was a very great blessing in time of sickness, and he would be very sorry, for their sakes, to see the institution done away with.

Mr. Hone thought they would be in a very anomalous condition if they had not a refuge for those who were struck down by accident, or afflicted by disease.

Mr. Byrne said they must pass the presentment, but there were a great many people who were not at all pleased with having to assist in paying it.

Baron de Robeck said that perhaps those persons did not know the benefit of such an institution.

The Chairman said he might inform them that at last assizes some of the cesspayers having been informed that the auditor had made an objection to that sum of £47, employed counsel, and appeared before the judge

and the judge had given it as his opinion that they were empowered to grant that sum. It was a further sum of £47 which was obtained as a supplementary grant from the Maintenance Fund.

Mr. Cooke Trench said that the sum of £47 was what the cesspayers themselves voted, but they could get no qualified person to take the situation for that, and the surgeon at present had a considerably larger salary, which was paid out of the Maintenance Fund; and the question had been raised whether it would be legal to apply any portion of the Maintenance Fund in this manner. That was the question which had come before the judge, and he had ruled that it was legal to supplement the surgeon's remuneration in the manner mentioned.

Both applications were unanimously granted.

#### The Health of Ireland.

FOR the week ending January 15, the average annual death-rate per 1,000 represented by the deaths registered in the sixteen principal towns of Ireland was 33·3, the respective rates for the several districts being as follow, ranging in order from the lowest to the highest: Queenstown, 10·1; Sligo, 14·6; Lurgan, 14·7; Galway, 16·7; Londonderry, 20·6; Wexford, 21·5; Dundalk, 23·0; Cork, 24·5; Waterford, 29·0; Clonmel, 30·8; Kilkenny, 32·7; Dublin, 34·2; Belfast, 37·9; Drogheda, 46·2; Newry, 50·6; and Limerick, 54·2. The deaths from the seven principal zymotic diseases in the 16 districts were equal to an annual rate of 3·5 per 1,000. Among the 127 deaths from all causes registered in Belfast, are 3 from scarlatina, 5 from whooping-cough, 2 from fever (1 typhoid and 1 simple continued), and 1 from diarrhœa.

The mortality in twenty large English towns, including London (in which the rate was 22·6) was 23·6 per 1,000; in Glasgow the rate was 24·1; and in Edinburgh 23·1.

In the Dublin district the deaths represent a rate of 34·9. Twenty-seven deaths from zymotic diseases were registered, being seven under the number for the preceding week, and 20 under the average for the second week of the last ten years.

The registered deaths (2) from typhus are 6 under the number for each of the two preceding weeks. Forty-two new cases of the disease were admitted into the principal hospitals, being three under the admissions for the preceding week, and 9 under the number for the week ending 1st inst.; 157 typhus patients remained under treatment, being 9 over the number in hospital on the previous Saturday; no deaths from typhus occurred in any of these institutions during the week.

#### TANNATE OF QUININE.

ACCORDING to Dr. Becker (*La Presse Medicale Belge*), the value of this salt consists simply in its tastelessness. For this reason it is specially useful for children. The dose should always be double that of quinine sulphate, because it contains less active quinine. The salt is absorbed with more difficulty than other quinine salts. It is well to aid its absorption by the simultaneous administration of wine. Dr. Becker considers that the production from hydrochlorate is preferable to that from the sulphate.

## IRISH POOR-LAW INTELLIGENCE.

### THE INDISCRIMINATE DISTRIBUTION OF BLANK TICKETS FOR MEDICAL RELIEF.

The following important circular letter has been re-issued by the Local Government Board for Ireland :—

TO THE HONORARY SECRETARY OF EACH DISPENSARY  
COMMITTEE IN IRELAND—

SIR,—The attention of the Local Government Board for Ireland has been drawn to irregularities, which are stated to be of frequent occurrence, in the issue of tickets for medical relief under the provisions of the Irish Medical Charities Act. These irregularities are stated to be as follows :—

1. A practice on the part of persons who are legally authorised to issue tickets for medical relief of signing blank medical relief tickets "en bloc," leaving them to be filled up and issued by other persons.

2. The issue of tickets for medical relief for persons who cannot fairly be considered to be "poor persons" within the meaning of that term as used in the 9th section of the Medical Charities Act.

In regard to the first of these irregularities, there can be no doubt that the practice is not only contrary to the dispensary regulations in regard to the issue of tickets for medical relief, but is also at variance with the provisions of the Medical Charities Act, the 9th section of which empowers certain persons therein described to afford medical relief by tickets addressed to the medical officer, but does not contain any provision authorising the persons empowered to issue tickets to delegate that power to other persons.

In regard to the class of persons to whom tickets for medical relief may be issued, the Medical Charities Act has, no doubt, placed the responsibility of determining whether an applicant for medical relief is or is not a "poor person" within the meaning of the Act, upon the persons who are authorised to afford such relief at their discretion ; but it is obvious that the discretion ought to be exercised so as to prevent as far as possible the abuse complained of, thereby charging upon the rates the cost of medical relief which ought to be borne by the patient or his friends, and burthening the medical officer with the duty of affording gratuitous medical aid to persons for whose benefit the provisions of the Medical Charities Act were not intended by the Legislature.

The Board have thought it right to bring this subject under the consideration of the dispensary committee, in the hope that they will by every means within their power discourage the abuses referred to.

The Board desire to add in reference to the subject that they have sometimes received communications

from members of dispensary committees and others evincing a desire to establish a system by which tickets for medical relief might be issued, subject to the payment of a regulated scale of fees for persons who, though not strictly "poor persons" could not afford to pay the usual fees charged for medical attendance. Such a system, however, would not have been in accordance with the provisions of the Medical Charities Act, and could not be made compulsory upon the medical officer ; but the Board think that the existence of such a desire shows that to some extent the abuse complained of may be traced to the scale of fees charged to private patients, and that it might be deserving of consideration whether some arrangement might not be made by which such fees could be graduated in some way in accordance with the circumstances of the patients.

By order of the Board,

(Signed) B. BANKS, Secretary.

[This expression of the opinion of the Local Government Board was much needed, and no doubt it will produce a salutary effect. It is notorious that medical relief tickets are in numerous instances as much an article of trade as potatoes or coals. They are part of the stock in-trade of the local provision dealer or shebeen proprietor, and are used by him for the purpose of attracting business to his shop. The "poor" person who is rich enough to keep a "book" at the shop, and who pays regularly and substantially, looks upon it as his right to get one of the signed blank tickets which are left with the shop assistant, and to be allowed to fill it up in the name of anyone whom he pleases, while the neighbouring pauper who is not worth cultivating as a customer may walk on to the next committee man and wait upon his convenience for a ticket. It will be admitted that the issue of tickets in this way is a gross abuse. Moreover, we hold that the medical officer would be fully entitled in law to treat such a ticket as waste paper and refuse to attend upon it. The Medical Charities Act, sec. 9, empowers the committeeman "to afford medical relief by the issue of a ticket addressed to the medical officer directing him to afford medicine and advice to any poor person resident therein." Clearly, under this law, it is the committeeman and no other person who is to name the poor

person to whom the ticket is granted; and it is wholly illegal for such a functionary to order medical advice and medicine to be granted to an unknown person leaving it to the same third party to say who shall have the benefit of such an order. The Dispensary Regulations (Article 21) confirm this view. They order that the "medical officer" shall afford medical relief to any poor person presenting a ticket *as hereinafter* provided." The "*hereinafter*" runs as follows:—"The ticket and counterpart are *both to be filled up* by the person authorised to issue the ticket;" and again, "care should be to fill up the ticket . . . accordingly;" and again, "any further observation which *the grantor of the ticket* may desire to make for the information of the medical officer shall be written on the front of the ticket." It is only a ticket thus filled up that the medical officer is bound to honour; and we repeat that, in our opinion, he would be within his legal rights in refusing the authority of any ticket not so filled. But we deprecate any such refusal, and advise the medical officer in all cases to attend and do his duty, and he will then be in the best position to urge his complaint against the system of which he is the victim. His easiest course, we think, will be to collect a bundle of blank signed tickets and submit them to his committee to be cancelled. Whether or not his request be complied with he should then appeal to the Local Government Board, and we feel certain that the appeal would, if based on fair grounds, be not in vain.

As to the duty of the Board in such case there can be no second opinion. It is their function, when armed with the necessary evidence, to put a peremptory stop to the issue of tickets in this way. They should, and, we anticipate, would, inform the issuer, that ticket-granting per pot-boy cannot be tolerated; and that, in case it be persisted in, they will find it necessary to remove him from the committee.

The cure for this abuse is in the hands of the medical officers themselves; and if it pleases them not to put the Local Government Board in motion, they must content themselves to endure.

As to the question of fees referred to in the above-quoted letter, we rather object to the Local Government Board going out of its province to utter a hint on the subject. It is quite untrue that, as a rule Irish Poor-law medical officers are *exigent* in their demands, or that the small farmer is overcharged. Technically, the doctor's fee is £1, or even 10s. Practically, it is what the patient can afford, and it ought not to be less. The Local Government Board may very safely leave the amount of fees of Irish dispensary doctors to be regulated by the excessive supply, and little demand, which exists in most districts, and devote its energies to protecting the ratepayers and the medical officers against the prevalent participation of the majority of the lower middle-class population in the charitable relief provided at the public expense for paupers.

#### THE HEALTH OF IRELAND IN 1880.

FROM the yearly summary just issued by the Registrar-General for Ireland, it appears that 11,308 deaths were

registered in the Dublin district during 1880, being 35.9 in every 1,000 of the population, against a ten year average death-rate of 27.6; in the year 1879 the death-rate was 35.7 per 1,000. As pointed out in previous reports, the burial returns under the Public Health Act came into force in 1879, raising the number of deaths registered by about 10 per cent. over the number registered in previous years.

Omitting 300 deaths in public institutions from localities outside the Dublin district, the death-rate for last year is 35.0, the rate for the city being 37.8 (40.0 on the North side and 36.1 on the South), and for the suburbs 25.1. The rates for the several districts range from 20.5, the rate for Blackrock, to 42.2 for Meath street district.

In the fifteen provincial town districts the death-rates are as follows:—Sligo, 20.8; Queenstown, 22.3; Kilkenny, 22.4; Galway, 24.1; Drogheda, 24.9; Dundalk, 25.2; Newry, 25.3; Londonderry, 25.7; Limerick, 26.7; Wexford, 27.3; Belfast, 29.3; Lurgan, 29.5; Cork, 30.8; Clonmel, 32.1; and Waterford, 34.4.

The rate registered in London was 22.1; in Glasgow 22.4; and in Edinburgh 21.3 in every 1,000 of the estimated population.

The registered deaths in Dublin numbered 11,308—an increase of 73; this is the largest number of deaths registered in any one year since registration commenced.

The deaths from zymotic diseases showed an increase of 520 on the previous year, and 930 above the average number registered during the ten years 1870-79. Small-pox caused 266 deaths, compared with an average of 270 for the ten years 1870-79. In referring to the average for the ten years 1870-79, it must be noted that the first small-pox epidemic of 1871-73, which culminated in 1872, is included in the decade. The epidemic which is now subsiding, commenced at the end of the year 1877, reached its height in the year 1878, continued with little abatement during the year 1879, and substantially diminished in the year 1880. Measles caused 544 deaths, compared with an average of 153; thus measles has been again unusually fatal. Scarletina caused 544 deaths, against 392 in 1879, and compared with an average of 296 for the ten years 1870-79; this is the highest number registered since registration commenced, except in 1874, when 834 deaths were registered. Diphtheria caused but 36 deaths against 49 in the preceding year, and compared with an average of 32 for the past ten years. Whooping-cough caused 376 deaths against 98 in the previous year, and compared with an average of 152. Fever caused 393 deaths against 337 deaths in the year 1879, and compared with an average of 317. Diarrhoea was unusually fatal, and caused 424 deaths against 167 in 1879, and compared with an average of 233; this is the highest number of deaths from diarrhoea recorded in the Dublin district in any one year. Two hundred and eighty-four of these deaths were registered in the third quarter of the year.

Taken altogether, phthisis and other diseases of the respiratory organs caused 3,197 deaths, against 3,794 in 1879, or a decrease of 597. This diminution of deaths from chest affections must be mainly attributed to the less severe weather in the first quarter of 1880, as compared with that of the corresponding period of 1879.

#### THE IRISH PROVINCES.

During the year 5 deaths from small-pox were registered in Belfast, 1 in Londonderry, 1 in Newry, and 1 in Sligo, but none in any of the eleven of the other districts.

Measles was prevalent in Belfast during the first six months of the year, in Cork during the first and fourth quarters, in Drogheda during the first quarter, in Queenstown during the third quarter, and (as already indicated) in Waterford during the fourth quarter.

Scarlatina, which had been very fatal in Cork during the last quarter of 1879, continued prevalent throughout the first six months of 1880; the deaths from it during the second half of the year also were numerous, and the total number for the year amounted to 204, equal to 2.2

per 1,000 of the population. The disease was prevalent in Drogheda and Waterford during the greater part of the year, and in Limerick, Wexford, and Sligo during the fourth quarter.

Diphtheria caused 20 deaths in Belfast, 13 in Cork, 1 in Limerick, 3 in Londonderry, 2 in Sligo, and 1 in Clonmel.

Throughout the whole of the last two years whooping-cough has been prevalent in Belfast, the deaths caused by it in 1879 amounting to 258, while those for the year now ended were only 6 less in number. During the second quarter of last year this disease was prevalent in Queenstown and Londonderry, and in the third quarter it was prevalent in the latter district, and also in Newry and Dundalk.

In proportion to population deaths from fever were most numerous at Cork, the rate being 1·3 per 1,000.

As already stated, diarrhoea was very fatal in Waterford; there were also many deaths from that cause in Belfast.

## IRISH MEDICAL ASSOCIATION.

### REPORT OF THE PROCEEDINGS OF THE COMMITTEE OF COUNCIL,

*During the Half-year ended 7th December, 1880.*

(Read and adopted at the Meeting of Council held 11th December, 1880.)

*Continued.*

**Correction of Errors**—Sec. 27 (*verbatim*)—With regard to the correction of errors in registers of births and deaths it shall be enacted as follows:—

1. No alteration in any such register shall be made except as authorised by this Act.

2. Any clerical errors, whether they occurred before or after the commencement of this Act, which may from time to time be discovered in any such register may be corrected by any person authorised in that behalf by the Registrar-General, subject to the prescribed rules.

3. An error of fact or substance in any such register may be corrected by entry in the margin (without any alteration of the original entry by the officer having the custody of the register upon payment of the appointed fee, and upon production to him by the person requiring such error to be corrected of a statutory declaration (Form O, Schedule Three) setting forth the nature of the error and the true facts of the case, and made by one or more persons required by this Act to give information concerning the birth or death with reference to which the error has been made, or in default of such persons, then by two credible persons having knowledge of the truth of the case; and it shall be the duty of the registrar, on becoming aware of any error in fact or substance, to send a requisition to the informant requiring him to attend and correct the same.

4. Where an error of fact or substance (other than an error relating to the cause of death) occurs in the information given by a coroner's certificate concerning a dead body upon which he has held an inquest, coroner, if satisfied by evidence on oath or statutory declaration that such error exists, may certify under his hand (Form D, Schedule Three) to the officer having the custody of the register in which such information is entered the nature of the error and the true facts of the case as ascertained by him on such evidence, and the error may thereupon be corrected by such officer in the register, by entering in the margin (without any alteration of the original entry) the facts as so certified by the coroner, and such declaration or certificate shall accompany the quarterly certified copies.

And whenever such correction shall have been made in any entry of birth or death subsequently to the transmission to the general register office of the return

of certified copies containing such entry, such declaration or certificate of coroner shall be forthwith sent through the post office to the Registrar General, who shall cause such correction to be made in the certified copy, and such addition shall be held to be good as if part of the original entry.

Sec. 36 (*verbatim*).—"A prosecution or indictment for an offence under this Act, shall be commenced at any time within three years after the commission of such offence."

It is understood that legal proceedings against defaulters under this Act are in future to be taken by the police, and not by the registrars as hitherto.

Sec. 36 (*Definition of Terms*).—The term "public institution" means a prison, lock-up, workhouse, barracks, lunatic asylum, hospital, or any prescribed public, religious, or charitable institution:

The term "house" includes a public institution as above defined:

The term "occupier" includes the governor, keeper, master, matron, superintendent, or other chief resident officer of every public institution, and where a house is let in separate apartments or lodgings includes any person residing in such house who is the person under whom such lodgings or separate apartments are immediately held, or his agent, and by such term shall all the persons above-mentioned be described when acting as informants:

The term "relative" includes a relative by marriage:

The term "prescribed" means prescribed by regulations made from time to time in pursuance of section eleven of the principal Act or of this Act:

The term "appointed fee" means the fee specified in the second schedule to this Act:

The term "guardians" includes any body of persons performing the functions of guardians within the meaning of the Acts relating to the relief of the poor:

Secs. 41 and 42 provide that the new Act shall not come into operation until the 1st day of January, 1881; that it shall extend only to Ireland, and that, so far as consistent it shall be taken as one with the unpealed portion of the old Act.

### SECOND SECTION.

**Fees to Registrars.**—Upon the registration of a birth when the child is more than three months old, if it is not more than twelve months old, to the Registrar (unless the delay is occasioned by his failure to issue a requisition, or otherwise by his default) *two shillings and sixpence*, and if it is more than twelve months old, and is registered with the authority of the Registrar-General, to the Registrar (unless the delay is occasioned by his failure to issue a requisition, or otherwise by his default) *five shillings*, to be paid by the informant or declarant.

Upon the registration of a death with the authority of the Registrar-General after the expiration of twelve months to the Registrar (unless the delay is occasioned by his failure to issue a requisition, or otherwise by his default) *five shillings*, to be paid by the informant or declarant.

For taking, attesting, and transmitting a declaration made by an informant respecting a birth which occurred in another district, to the Registrar attesting the declaration *two shillings*, to be paid by the informant.

For entering the baptismal or other name of a child upon certificate produced after registry of birth, to Superintendent Registrar or Registrar *one shilling*, to be paid by the person requiring the name to be entered.

Correction of error of fact or substance in register, to Superintendent Registrar or Registrar *two shillings and sixpence*, to be paid by the persons requiring the error to be corrected.

For every search, to the Registrar, to be paid by the applicant for the search, *one shilling*.

For a certified copy of any entry given by the Registrar, *two shillings and sixpence* to the Registrar, to be

paid by the applicant (under the old Act *one shilling* was the fee).

FOURTH SCHEDULE.—REPEAL.

Session and Chapter.	Title or Abbreviated Title.	Extent of repeal.
25 Vict. c 11	An Act for the Registration of Births and Deaths in Ireland. (20th April, 1863.)	Preliminary to Act, from the words "general search" to "stating objects of search." Section twenty-six from the words "in case of the death" to end of section. Section thirty-one, thirty-two, thirty-three, thirty-four, thirty-five, thirty-six, thirty-seven, thirty-eight, forty-four, forty-six, fifty-one, and fifty-five.
26 & 27 Vict. c. 90.	The Registration of Marriages (Ireland) Act, 1863.	Section twenty-one.

Although the new Act is not all that could be desired in the interest of the Registrars, it is a decided improvement upon the former one, as it relieves the Registrars of many irksome duties for which they receive no remuneration, viz. :—

1. The issuing to informants of notices requiring registry of births and deaths in all cases; such notices in future are to be sent only to defaulters, *i.e.*, persons who do not register births within forty-two days, or deaths within five days, after their occurrence.

2. Attendance (with book) before the justices for the purpose of having errors corrected; under the new Act such attendance is dispensed with, and the Registrar is entitled to a fee of two shillings and sixpence for correcting each error of fact or substance.

3. Attendance at the Superintendent-Registrar's office (with book) to meet an informant requiring a birth to be registered after three months; the old Act allowed a fee of two shillings and sixpence for that duty, but it was seldom received; under the new Act the informant in such cases must come to the Registrar, who need not register the birth until the fee is paid.

On the whole the new Act diminishes the work of the Registrars while affording them increased remuneration.

TRALEE GUARDIANS.

SALARIES.

MR. KEANE, in pursuance of a notice of motion, moved that the salary of the medical officer to be appointed for the district of Brosna be £150 a year.

The Chairman said that at present they were not going to appoint anyone.

Mr. Roche stated that the meeting of the dispensary committee, from which the recommendation of the increase of salary emanated was informal.

Mr. O'Connor mentioned that he was aware that a doctor, whose degrees are second to no other in Kerry, could be got for £90 a year.

After some further discussion a division was taken, and it was decided to appoint a medical officer at a salary of £90 a year.

LIST OF ENTRIES IN THE REGISTER OF THE BRANCH MEDICAL COUNCIL (IRELAND) FOR THE MONTH OF JANUARY, 1881.

DECEMBER 31st, 1880.—MacMath, Arthur William; 1 Windsor Road, Rathmines, co. Dublin; Lic. R. Coll. Surg. Irel. 1880.

JANUARY 3rd, 1881.—Brady, Francis Forster; 1 Neptune Terrace, Sandycove, co. Dublin; Lic. R. Coll. Surg. Irel. 1880.

5th.—Corcoran, Edmund; Enniscorthy, co. Wexford; Lic. K. Q. Coll. Phys. Irel. 1880, Lic. R. Coll. Surg. Irel. 1880.

11th.—Roulston, William; Beragh, near Omagh, co. Tyrone; M.D. 1880 and M.Ch. 1880 Q. Univ. Irel.

18th.—Campbell, Richard; Ballyhaakin, Mill Isle, co. Down; M.D. Q. Univ. Irel. 1880.

11th.—Cuscaden, George; Alexandra House, Wexford; Lic. R. Coll. Phys. Edin. 1880, Lic. R. Coll. Surg. Edin. 1880.

14th.—Gem, William; Hampton Terrace, Warwick; Lic. R. Coll. Surg. Irel. 1880.

12th.—Martin, John Charles; Killeahandra, co. Cavan M.B. 1880 and B.Ch. 1880 Univ. Dub.

19th.—Kernan, James; 4 Bayswater Terrace, Kingstown, co. Dublin; Lic. R. Coll. Surg. Irel. 1879, Lic. 1880 and Lic. Mid. 1880 K. Q. Coll. Phys. Irel.

21st.—Hanna, William Gordon; Magherafelt, co. Londonderry; M.D. Q. Univ. Irel. 1880.

26th.—Cusack, Henry; Cahir, co. Tipperary; Lic. R. Coll. Surg. Irel. 1879, Lic. 1880 and Lic. Mid. 1880 K. Q. Coll. Phys. Irel.

25th.—Hackett, Robert Isaac Dalby; Castle Armstrong, Ballycumber, King's county; M.D. 1880 and M.Ch. 1880 Q. Univ. Irel.

27th.—Dillon, Valentine Plunkett; Ballaghaderreen, co. Mayo; Lic. 1880 and Lic. Mid. 1880 K. Q. Coll. Phys. Irel., Lic. R. Coll. Surg. Irel. 1879.

27th.—Hickman, James; 42 Robert Street, London, N.W.; Lic. R. Coll. Phys. Edin. 1880, Lic. R. Coll. Surg. Edin. 1880.

28th.—Moon, Daniel; Ballydiret, Aghadowey, co. Derry; Lic. R. Coll. Surg. Irel. 1880.

28th.—O'Brien, Richard Francis; Villerstown, co. Waterford; Lic. R. Coll. Surg. Irel. 1880, Lic. 1880 and Lic. Mid. 1880 K. Q. Coll. Phys. Irel.

MEMORANDUM.

The following names have been restored to the Register, per order of Council :—

Feb. 15, 1861.—Eaton, Usher Beere; Mitchelstown, co. Cork; M.D. Q. Univ. Irel. 1880, Lic. R. Coll. Surg. Irel. 1861.

September 5th, 1876.—McKeogh, Thomas; Innisboffin, co. Galway; Lic. Fac. Phys. and Surg. Glas. 1875, Lic. Apoth. Hall Dub. 1876.

September 10th, 1876.—Hamilton, James; 5 Pelham Street, South Kensington, London, S.W.; M.B. 1875 and M.Ch. 1875 Q. Univ. Irel.

MEMORANDUM.

The following names have been erased from the Register of the Branch Medical Council (Ireland) during the month of December, 1880, pursuant to the 14th Section of the Medical Act, no reply having been received to several letters of application, or as having been reported dead or ceased to practise, viz. :—

Fleming Christopher; 14 Brookfield Terrace, Donnybrook, co. Dublin. Dead.

Lever, John; Gowran, co. Kilkenny. Dead.

McCorry, Peter; Lurgan, co. Armagh. Dead.

Jencken, Ferdinand; 22 Anglesey Place, Kingstown, co. Dublin. Dead.

Jennings, Alexander; Saintfield, co. Down. Dead.

Caroll, Walter John; Tambaroora, Sydney, N. S. W. No reply.

Sedley, Anthony Kyrle; Kanturk, co. Cork. Dead.

West, Francis John; District Asylum, Omagh, co. Tyrone. Dead.

Lawlor, Michael; Tralee, co. Kerry. Dead.

# IRISH POOR-LAW INTELLIGENCE.

## WHAT IS A "SUCCESSFUL" RE-VACCINATION?

This question is about to be tried out at the next County Tyrone Assizes in an action now pending by Dr. Duncan, the Medical Officer of the Fintona Dispensary, against the Board of Guardians of his Union. The facts are these: By the Vaccination (Ireland) Amendment Act of 1879 (42 and 43, cap. 70, sec. 6, "Irish Med. Directory," page 618), it was enacted as follows:—

Whereas, by 26 and 27 Vic., cap. 52, sec. 5, it is provided that the Board of Guardians shall pay to the medical officer of each dispensary district, in addition to any salary or allowance payable to him, the sum of one shilling for every person successfully vaccinated by him: Be it enacted, that the said section shall be and is hereby repealed; and the Board of Guardians shall pay to every such medical officer for every person successfully vaccinated or every person re-vaccinated by him within his dispensary district, after the passing of this Act, the sum of two shillings.

In the summer of last year an epidemic of small-pox broke out in Dr. Duncan's district, and, partly in consequence of his exertions, and partly by reason of the panic which it created, a great number of persons resorted to him, both for vaccination and re-vaccination. These he duly operated upon and inspected on the eighth day, and charged against the Guardians the vaccinations which produced the usual vesicle and the re-vaccinations whether or not they produced such result. The Guardians demurred to paying for any cases in which the vesicle, which they supposed to be the essential mark of success, was not produced, and, on consulting the Local Government Board, they were encouraged in this view, and given to understand that they need not pay for re-vaccinations which proved unproductive of a vesicle. It will be observed, from perusal of the section above quoted, that such a judgment as this was carefully provided for by the framers of the Act, and that they went to the trouble of drawing a marked distinction between the case "successfully vaccinated" and the case "re-vaccinated," whether successful or not, and every public vaccinator and every author who has written on the subject recognises the non-essentiality of a vesicle as a sign of effective and workmanlike re-vaccination.

The ruling of the Local Government Board and the refusal of the Guardians to pay, strike, obviously, not only at the chief purpose of the section, but at the future assiduity of public vaccinators, because if it were ruled that

a vaccinator is only to be paid for the rare cases of re-vaccination which produce a pustule, very few of them would trouble themselves to re-vaccinate, and small-pox would go unchecked. Therefore, Dr. Duncan very properly thought it necessary to bring the matter under the notice of the Council of the Irish Medical Association, who—after consideration of the circumstances—decided to support him in obtaining legal redress.

An extension of time to plead was obtained the week before last by the Guardians without opposition on the part of the plaintiff; and, since then, the Judges have ordered that the law of the matter shall be argued before them on demurrer. Should the Guardians persist in their defence to Dr. Duncan's claim, we are confident that they will find themselves adjudged wrong. That they are so seems quite clear; and respectful as we must necessarily be to the superior legal wisdom of the Local Government Board, we can hardly conceive the meaning of the advice upon which the Guardians have acted.

## LIST OF ENTRIES IN THE REGISTER OF THE BRANCH MEDICAL COUNCIL (IRELAND) FOR THE MONTH OF FEBRUARY, 1881.

JANUARY 29th.—McCredy, Robert Dean Wills; Gosforth, Newcastle-on-Tyne; M.B. 1879 and M.Ch. 1879 Univ. Glas.

Jan. 31st.—Boyd, Joseph; Lakeview, co. Roscommon; Lic. 1880 and Lic. Mid. 1880 K. Q. Coll. Phys. Irel., Lic. R. Coll. Surg. Irel. 1880.

FEBRUARY 9th.—Murray, Arthur Hill; Edenderry, King's co.; Lic. R. Coll. Surg. Irel. 1880.

10th.—Givan, John; Aughnacloy, co. Tyrone; Lic. Fac. Phys. and Surg. Glas. 1880.

10th.—Foley, Thos. McCraith; Templetoohy Rectory, Templemore, co. Tipperary; Lic. R. Coll. Surg. Irel. 1880, Lic. Apoth. Hall, Dub. 1881.

16th.—Brady, Edward; 17 Bridge Street, Cork; Lic. R. Coll. Phys. Edin. 1880, Lic. R. Coll. Surg. Edin. 1880.

21st.—Fritchard, Thomas; Scotthouse, Clones, co. Monaghan; M.D. Q. Univ. Irel. 1880.

22nd.—Furlong, Thomas Augustine; 17 Merrion Row, Dublin; Lic. Apoth. Hall, Dub. 1875.

22nd.—Jacob, Wm. Gardiner; Maryborough, Queen's co.; Lic. R. Coll. Surg. Irel. 1880.

## MEMORANDUM.

The following names have been erased from the Register of the Branch Medical Council (Ireland) during the month of February, 1881, pursuant to the 14th Section of the Medical

Act, no reply having been received to several letters of application, or as having been reported dead or ceased to practise, viz. :—

Dowdall, Edward; Banbridge, co. Down. Dead.  
Moylan, John Barry; Waterfall House, Richmond, co. Dublin. Dead.  
Beakey, Andrew Hyland; Arklow, co. Wicklow. Dead.  
Layng, William; Kanturk, co. Cork. Ceased to practise.  
Labatt, Hamilton; 1 Upper Fitzwilliam Street, Dublin. Dead.  
Tracey, Maurice Charles; Army Medical Department. Dead.

#### SPECIAL MEMORANDUM.

RESTORE to Medical Register (same having been erased in error on report of death), viz. :—

Registered June 17th, 1868.—Bradshaw, Benjamin Frederick; Kenhardt, Cape Colony; Lic. R. Coll. Surg. Irel. 1868, Lic. 1868 and Lic. Mid. 1868 K. Q. Coll. Phys. Irel.

### COLERANIE UNION.

#### THE EXAMINATION OF LUNATICS.

THE Chairman remarked that £8 had been charged by several of the dispensary medical officers of the Union for expenses incurred in the examination of persons supposed to be insane. The accounts had been certified by two of the magistrates resident in their respective districts.

Mr. Moody—I think in all those cases in which the friends are in a position to pay the fees, that it is unfair that the ratepayers should be called upon to pay the expenses.

The Clerk here produced the Act, and read the section bearing upon the point, as follows.—

Notwithstanding anything in Section 10 of the Act of the Session of Parliament held in the 30th and 31st year of the reign of her present Majesty, c. 118, to the contrary, it shall be lawful for any two Justices causing any person to be examined by any medical officer as therein mentioned, if they think fit so to do, to make an order under their hands and seals upon the Guardians of the Union to which such person belongs, for such reasonable remuneration to such Medical Officer, and for the payment of all other reasonable expenses in or about the examination of such person, not exceeding in the whole the sum of £2.

The Chairman—The magistrates having certified, we must pay; but I confess I thought the order was compulsory upon the Justices, not optional, as it appears from the Act.

The Clerk—Yes; but it would seem that the magistrates may not certify unless, after making inquiries into the circumstances of the people, they may think it right to do so.

[It seems to be anomalous that the rates should pay for the medical examination of a lunatic whose friends are able, and, perhaps, willing to bear the expense, but it is to be recollected that the committal of a lunatic under the Dangerous Lunatics Act is a procedure under the criminal law, effected through the agency of the police, and to compel the patients' friends to pay would be the same in principle as to oblige them to pay the expense of arresting an ordinary law-breaker and sending him to gaol. It is well worthy of consideration, however, that these committals under the Dangerous Lunatics Act are, in very many instances, used as a short cut instead of the troublesome, dilatory, and

expensive method of admitting harmless patients to the asylum. Not a few of the "dangerous" lunatics are very innocent of harm, but are certified on the same principle that coroners' juries always finds suicide to be temporary insanity. It is a strange anomaly that no legal method exists of certifying a harmless pauper in Ireland; the dispensary doctor—if served with a ticket—must examine and treat the patient, but it is none of his business to certify his condition of mind, and, in point of fact, the duty of certifying in such cases is performed by the Poor-law Medical Officers of Ireland purely out of compassion.—Ed. M. P. & C.]

### CASTLETOWN DISPENSARY DISTRICT.

At an extraordinary meeting of the committee, Dr. Owen P. Kerrigan was unanimously elected medical officer of the district in room of his brother, Dr. L. Kerrigan, resigned.

The following resolution was unanimously passed at the same meeting :—"We hereby express our marked approval of the manner in which our late medical officer, Dr. L. Kerrigan, discharged his duties towards the poor under his care—from the kindness and strict attention he invariably bestowed."

### WATERFORD UNION.

#### A SERIOUS STATEMENT.

On the application for admission of a man who was suffering from scrofula, the relieving officer said he had given seventy-two tickets to people for medical relief outside at the dispensary, and they were sent back to him with a statement that he should give these people tickets for the house hospital, though it is full.

The Clerk—You should do your duty, and make a report, so as to have the matter in order.

This boy, Hanlon, is suffering from scrofula, and the doctor outside, will not treat him for the disease. He insists upon having the boy sent to the house hospital, though the Local Government Board say these are cases for outside treatment.

The Clerk—I will take down Mr. Moloney's statement.

Mr. Fisher—There is no room at all in the hospital at present for these people.

### MULLAHONE DISPENSARY.

A MEETING of the committee was held on January 14, for the election of a medical officer to replace Dr. Going, who has retired after thirty years' faithful service. There were three candidates, viz., Dr. Ryan, New Pallas; Dr. Kenny, Carrick-on-Suir; and Dr. Hickey, Kilkee, county Clare. The voting was as under :—

For Dr. Ryan, seven; for Dr. Kenny, two; for Dr. Hickey, one.

Dr. Ryan was declared duly elected.

### SLIGO UNION.

READ the following note from the Collosney Dispensary Committee :—

The Committee took into consideration the well-founded complaints of their medical officer as to the abuse in the issue of tickets for medical relief. It appears

that some members of the Committee and wardens are in the habit of largely issuing tickets by deputy. This leads to great abuse, and prevents due caution and discernment being used by the party who alone is legally entitled to issue tickets, and the Committee hereby direct the doctor in no case to act on any ticket not duly filled up and signed personally by the party purporting to issue it. This resolution is taken in consequence of a letter from the Local Government Board calling our attention to this matter. The number of tickets issued in 1880 was 1,763, being an excess of nearly 1,000 over the yearly average of Dr. Malony's predecessor.

Upon this the following discussion took place:—

The Chairman said he considered it very wrong for members of the dispensary committee and wardens to be issuing tickets by deputy.

Mr. Simpson—Why does the doctor attend on them?

Chairman—He cannot tell at the time which is genuine and which is not. I think the committee are right to give their opinion upon it. They give good advice.

Major Wood-Martin—We should sanction what they have done.

Mr. Walsh considered it bad advice. It would be better for the doctor to go on any ticket he gets, and afterwards, if he finds the ticket was not properly issued, to prosecute the guilty parties.

Mr. Walker agreed with Mr. Walsh. Dispensary doctors were bound to attend on a red ticket when they got one; but, if they find out afterwards that the ticket was not a genuine one, they can sue for their fee. It was hard on the doctors, but it would be wrong to give them the power of questioning a ticket.

Mr. Barber—People having the power to issue tickets should be cautious how they do so.

Mr. Nelson—But it would be a serious matter if a doctor could question the genuineness of a ticket. He might make a mistake.

Mr. O'Connor considered it better not to give the advice suggested by the committee to the doctor. He was sure, when the matter was made public through the columns of the press, that people would be more cautious.

Mr. Tute considered that, so far from sanctioning the act of the committee, the guardians should repudiate it.

Mr. Walsh would not make any doctor the judge of the handwriting of a member of a dispensary committee.

Mr. Duke—But what remedy has the doctor? They cannot recover their fee from the person who signs a ticket for another.

Mr. Walker considered a doctor had a good action against a person who allowed tickets to be issued in this way, and if he attended a person who could pay a fee on such a ticket he could recover his fee.

Mr. Walsh—And I believe they would be made pay.

Mr. O'Connor asked how they could meet a case where a person went to the house of a committee man or warden, and asked for a ticket for a sick relative who was dangerously ill, and required instant attendance? If the tissue-issuer was not at home, surely it would be no harm for a member of a family to issue a ticket. If there was no other committee-man in the district, how could the thing be done? Or if the party made a wrong representation of their circumstances, surely the committee-man or warden was not to be held responsible?

Mr. Walker—They are bound to possess a knowledge of their locality.

Mr. O'Connor—But they may be living two miles away.

Mr. Walker—Even so. I think no member of a dispensary committee should sign a ticket for a patient not in his district, and in regard to whose circumstances he is totally ignorant. I have refused tickets to persons whom I considered able to pay for a doctor, and away the persons applying flew to Sligo, where they got accommodating gentlemen to give them a ticket in the shot of a gun.

Major Wood-Martin said that was his experience also. Country guardians refused to give tickets, knowing the circumstances of the people, but the tickets were soon got in Sligo town.

Mr. Collery—But is not a member of a committee living in Sligo just as capable of signing a ticket as a gentleman living in the country.

Mr. Walker—Yes, if he knows the circumstances of the people, as well as a person living in the district, which I deny.

Mr. Walker—I know people with plenty of land and six or seven cows, who try to get medical relief for nothing.

The chairman said the question now before the meeting was—would they sanction this minute of the dispensary committee?

Several guardians objected to doing so.

Major Wood-Martin—But we should do something to prevent a member of a dispensary committee signing his name to a block of tickets, and allowing some irresponsible person to issue them to whoever likes to ask for one.

The guardians made a minute approving of the action of the committee in regard to bringing the state of the old road before the grand jury; but, in regard to the other matter, they refused to endorse the action of the committee with reference to the direction given to the doctor not to act in certain cases of dispensary tickets.

#### THREATENED SUSPENSION OF BELFAST GUARDIANS.

ON Tuesday week, at a meeting of the Belfast Board of Guardians, Mr. David Taylor, J.P., presiding, a letter from the Local Government Board was read in reference to the proceedings at recent meetings, and the omission to discharge all the business which came before them. Their attention had been called to the minutes of the board of the 8th inst., in which was the following entry:—"At 6.40 the board adjourned, leaving a considerable portion of the ordinary business undisposed of." They requested their inspector, Mr. Hamilton, to obtain a statement giving the details of the business which was left unfinished, and he found that many important matters connected with the management of the union had not been disposed of. They also observed, from the reports in the public Press, that the proceedings of that meeting had been of a most disorderly and irregular character. Attention was also called to the meeting of the 22nd inst., and to the statement that the board rose at 3.18 p.m. leaving a portion of the business held over from last board day, and nearly all the business of this day undisposed of. The Local Government Board found that the omission to finish the business was caused by the disorderly nature of the proceedings and by the unseemly language of some of the members, and the Board have noticed from the reports in the public Press that the absence of decorum which has been so remarkable on the two days specially referred to has also characterized the proceedings of the guardians on many other recent occasions. The Local Government Board cannot allow this state of things to continue. They therefore must express an earnest hope that the guardians will on next board day endeavour to dispose of the business remaining over from previous meeting, as well as the ordinary business of the day, as the Local Government Board would regret to have to exercise the powers vested in them by sec. 18, 10 Vic., cap. 31, in order to secure the due and effectual execution of the Irish Poor Relief Acts in the Belfast Union. After a lengthened and animated discussion, in which, as usual, Mr. John Rea took the most prominent part, it was agreed to inform the Local Government Board that their letter would be discussed at an early day.

## DROMAHAIR SANITATION.

At last meeting of the guardians the clerk said Dr. Hamilton, of Dromahair, sent in a number of sanitary reports, in which it was stated some people in his district kept cattle in their houses. There was also a report from Dr. Mulloy, stating that there were houses in Manorhamilton having neither yards or ash pits. There were three houses on the Commons, a house in Church Lane, and a house in Castle Street, so circumstanced. He recommended that the board should provide the necessary accommodation, charging same to the owners of the houses.

Chairman—How can we do that ?

Mr. Algeo—As a sanitary body we have great powers.

Mr. Palmer—Has a sanitary officer power to force admission into premises in order to inspect it ?

Clerk—Certainly.

Mr. Palmer said the reason he asked was that he knew where the sanitary inspector was refused admission to houses in Dromahair, where it was known cattle were kept with the family, although those parties could well afford to build out-houses for their cattle. A good deal of filth would naturally be got in such houses, but what was the inspector to do when he could not get in to see it ? He also knew a case where the door was shut against Dr. Hamilton when he went to inspect a house. He (Mr. Palmer) did not see that any steps were taken to enforce the law. He personally witnessed him going to the house, knocking at the door, and being refused admission ; and I am also aware cattle were kept in that house, and that the people could afford to have out-houses for them.

Clerk—An order can be got to force an entrance to the premises. The forms are here.

The Clerk, at the suggestion of the Chairman, was directed to give the owners notice that if a sewer was not made within a specified time, it would be made by the guardians, and the cost charged to them.

## BALLINROBE DISPENSARY.

A MEETING of the members of the Committee of Management was held for the purpose of electing a medical officer for the Cappaghduff dispensary.

There were applications from three, but only two candidates attended, Dr. H. J. Ingram and Dr. Leslie Maturin.

On a division there appeared—

For Dr. Ingram, 13.

For Dr. Maturin, 4.

## CORRESPONDENCE.

## ABUSE OF TICKETS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—On the 20th of November I received a red ticket to attend a servant in the employment and residing in the house of a rich merchant and landlord, who lives not in, but on the verge of my district. The ticket was issued by a warden, and in order, I suppose, to compel me to see the man, he inserted in the ticket the patient's native townland, which is in my district. The messenger was the master's son, and as the servant had met with an accident, I thought it better to see him and take the chance of getting my fee ; but as this was not forthcoming, I had the ticket cancelled, and wrote to the warden demanding my fee, but got no reply. A little more than a year ago a man came to me on a very wet night, asking me to see his wife in her confinement. He had no ticket with him, and being a small farmer, I told him he would have to pay me a reasonable fee, and with this understanding, and the case being urgent, I went with him about three miles off. About six weeks afterwards this man came to the dispensary and presented a red ticket dated back to the day on which I had attended

his wife, as payment of my fee. I laid this ticket before my committee, and it was not cancelled. All that was done was to sympathise with me. I could relate numerous cases of abuse in the issue of tickets, and would be inclined to look sharply after those who issued them, were it not that my district is very extensive and mountainous, and knowing well if I were to do so I should be more than doubly punished by wardens who do not know the law, and who would by way of revenge give red tickets instead of black ones to all comers. I believe this is one of the reasons why medical officers are slow to take action in these matters.

Yours truly,

A DISPENSARY DOCTOR.

[If medical officers find it incumbent or politic to submit to these abuses they need not complain of the system, for no one is to blame but themselves, and no public department could teach certain dispensary committeemen to be gentlemen or make road-side farmers honest. We don't urge medical officers to engage in hostilities with their committee, but we expect them temperately and firmly to assert their rights; and, if they won't do so, they must suffer the penalty of being too easy-going and timid.—Ed. M. P. & C.]

## IRISH UNION DRUGS AND THE LOCAL GOVERNMENT BOARD.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—If it is not an impertinent question I should like to know what is the use of the L. G. B. for Ireland ? Is it their intention to ever alter the old lists of medicines in accordance with the New Pharmacopœia ? What chloric ether at present means I am at a loss to discover, and as to what the strength of half the drugs supplied me by the contractor is, I am utterly at sea. This is a nice state of affairs as far as the poor are concerned. God help them ! If they have confidence in their doctor under present arrangements he won't do them much good. Talk of the Church Disestablishment ; landlord disestablishment ; the body requiring immediate disestablishment is the Irish Local Government Board. In my dispensary practice I have to give coloured water well sweetened, because I do not know either the strength or right name of the medicines supplied. This is a very nice thing to be said of a body who takes £3,000 yearly from the poor and starving farmer.

I am Sir, yours &c.,

A DISPENSARY HACK.

## REGISTRATION PETTY EXPENDITURE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In the regulations for the registrars of births, deaths, and marriages, the following paragraph under the head of " Allowances and Expenses " occurs :—

II. " Postage on registration business. A detailed account of postage should be furnished on the forms supplied for the purpose, and the different items of expenditure should be carefully entered in the proper columns. The envelopes of unprepaid letters addressed to the registrars on registration business should be retained by him as vouchers until his account is paid." Was there ever a more contemptible regulation printed ?

It is not even decent English. To whom does " him " and " his " in the last sentence refer ? Would it not be better to abolish this troublesome and badly-written regulation altogether, and allow the hard working and responsible registrars, say, 5s. or 10s. per quarter for stationery, as is done in nearly all branches of the public service ? Fancy keeping old unstamped envelopes as vouchers !

## IRISH POOR-LAW INTELLIGENCE.

## FEES TO PRISON SURGEONS FOR INQUESTS.

THE liability of Irish prison surgeons to give evidence gratuitously at inquests upon the bodies of prisoners is likely to come up for legal decision before long, although it was considered to have been settled in favour of the prison surgeons by a recent precedent. The case stands thus: Up to fifteen years ago it was always the custom to remunerate prison surgeons for such duty, but, at that date, it pleased the Castle authorities to issue a mandate that no further fees be allowed on this score. At that time the validity of this order was contested before the Judge of Assize, by Dr. Little, of Lifford, and the right of the prison surgeon to be paid for this testimony was established by the payment of the fee under the Judge's direction. Nevertheless, the Castle autocrats carried their point, because other prison surgeons were either unaware of this decision, or else did not care to fight the point with their superiors, and, thenceforth, the payment of an inquest fee fell into abeyance. After the passing of the Irish Prison's Act of 1878, the question again cropped up, and the Council of the Irish Medical Association then issued a circular (*Medical Press Supplement*, April 23, 1879) letter to all prison surgeons, in which they set forth their view of the law of the case. They pointed out that the 32nd sec. of the Coroner's Act withholds a fee from "the medical officer, whose duty it may have been to attend the deceased person as a medical officer of such institution." The institution here referred to is defined by the section to be either *a*, "a public hospital or infirmary," or *b*, "a county or other lunatic asylum," or *c*, "any public infirmary or other public medical institution," and the Council expressed its opinion "that the sick-ward of a prison is not included, or intended to be included, within the operation of this section, and that the medical officer of the prison is, therefore, entitled to the statutory fee payable for medical testimony."

Last year the question was again raised by the refusal of the coroner for Galway to pay a fee to Dr. Kinkead, surgeon of the prison, for inquest evidence. Dr. Kinkead consulted the Council of the Irish Medical Association, and the Council requested him to take the necessary steps to assert his rights, and guaranteed to pay the legal expenses of doing so. This, Dr. Kinkead considered that he had sufficiently done as he had applied to the Grand Jury for the fee, and it had been paid in spite of the

protest of the coroner who, it appears, acted upon instructions from Dublin Castle. Another case has now cropped up, and the coroner, having again refused, the Council of the Irish Medical Association has determined to put the question out of dispute, by asserting the right to a fee before such a tribunal as may be competent to decide it finally, and they have, therefore, requested Dr. Kinkead to take the necessary steps for this purpose.

We have stated above the interpretation of the law upon which the Association depends, and considering that that interpretation is sustained by the opinion of the late Lord Chancellor of Ireland, it may be taken decisively in favour of the prison surgeons upon the Coroners' Act. But a question might possibly arise as to whether a change in the law had been effected by the Prisons (Ireland) Act of 1878, whether the duty of giving medical testimony at inquests was imposed by that Act, and whether the General Prisons Board might have power to add such duty, for the future, to the functions of the surgeons.

Upon examination of the Prisons Act ("Irish Medical Directory," page 610), and the regulations issued by the Prisons Board, under its authority (page 325), we are satisfied that the rights of the prison surgeons to inquest fees is not altered thereby, and cannot be altered by any new rule of the Board. By sec. 12 of the Act, the Board may alter rules for regulating the duties of the officers, so long as those rules are not inconsistent with the Act 7, Geo. 4, cap. 74, but by sec. 27, the duties of prison officers are declared to be the same, or analogous to those "performed previously to the commencement of the Act, and they shall perform the same duties, as nearly as may be, as they shall be performing at same date." Again, under sec. 53, "the surgeon shall, forthwith, on the death of any prisoner, enter in his journal," all particulars respecting the death, but nothing is said as to his inquest duty. Again, by sec. 56, the coroner is obliged to hold an inquest on every prisoner dying within the prison, but nothing is said as to any function to be discharged in connection therewith. Lastly, the duties of the surgeon set down by the Prisons Board (which would, of course, be illegal, if they went beyond the limits defined by the Act) do not require from that officer any such duty as that sought to be now imposed. They speak of a post-mortem examination, but do not make it part of his duty to be present, or to testify at the inquest. Thus

it would appear that the inquest duty of the prison surgeon is strictly limited to those arising under the Coroner's Act, and we have already given good reasons for our belief that under this law he is entitled to his fee for evidence. In any case it will be satisfactory that the subject shall be put beyond dispute, as the Irish Medical Association proposes by a competent legal decision.

## CORRESPONDENCE.

### DISPENSARY DRUGS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I doubt very much the wisdom of publishing such a letter as the one signed "Dispensary Hack," in the last issue of the *Medical Press*.

A habit of exaggeration and hyperbole is one of the banes of this country. Men, who in the ordinary course of life are quiet, inexcitable people, no sooner stand up to address a public meeting, or even write a letter to a newspaper, than they seem to lose their heads altogether, and resort to language of which Mr. Boythorns, in "Bleak House," is only a faint and colourless example. I would wish to know if "Dispensary Hack" has ever had any difficulty in procuring whatever medicines or medical appliances he might want for the treatment of his dispensary patients? I have never had the slightest difficulty in getting anything I required. And instruments and medicines not on the List have been always supplied by the contractors at fair prices.

I am sure this is the experience of most medical officers, and I hope there are not many who are obliged to dispense coloured water to their patients, as "Dispensary Hack" acknowledges he has done.

One of the very few things we have reason to be proud of in Ireland is the superiority of the dispensary system over that of the sister country; and I am, therefore, glad that "Dispensary Hack's" letter appeared only in the sheet devoted to Irish Poor-law intelligence, and will not be seen by English and Scotch readers.

I am, Sir,

Your obedient servant,

A DISPENSARY MEDICAL OFFICER.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In your issue of March 16th, 1881, "Dispensary Hack" makes himself a good example of the old proverb, "A bad workman quarrels with his tools;" and I may reply, in his own words, with regard to the patients under his care "God help them," for their "Hack" is as unlikely to do them good with the medicines he has at present at his disposal, as with any future supply.

Most Poor-law medical officers have long felt the want of a revision of the Medicine List to keep up to times we live in. Yet any medical man will find drugs enough in the old List to meet most cases of illness, and need not be forced to substitute "water coloured and sweetened" for the more potent, though less palatable, medicines he now possesses. I should strongly recommend "Dispensary Hack" to invest in some commentary on the B. P., and read it; or, if this is too much trouble, let him ask some respectable grocer in his neighbourhood what "chloric ether" is, and no longer boast of his ignorance and incompetence.

Yours, &c.,

J. C. HALL, Medical Officer,  
Monaghan Union Workhouse.

[We understand and appreciate the complaint of "A Dispensary Hack," though we do not identify ourselves

with his hyperbolic mode of expressing himself. We agree with him that, under the arrangements for drug supply now maintained by the Local Government Board a medical officer is relegated to the therapeutics of twenty-five years ago, and is not afforded the means of treating the sick poor which any physician may employ for the benefit of his private patient. Moreover, the complaint is perfectly legitimate that the L.G.B., by its system, permits and encourages the supply of fraudulent drugs, and thereby makes it impossible for the medical officer to treat his patient on any certain plan. For example, the theoretic dose of Dover's powder in a given case may, in one union, be efficient, while in an adjoining one it will be totally inert, because in the latter the drugs are supplied on the well-known contractors' dodge; or a dose of the medicines of one contractor, which has been proved barely sufficient for its purpose, may almost poison the patient when the contract is handed over to a more honest firm. There is no hyperbole about these facts, and we repeat that every "Dispensary Hack" in Ireland, and, moreover, every dispensary patient, has good reason to complain that the Local Government Board for Ireland, with full knowledge of this disgraceful state of things, presides over and tolerates the successful dishonesty of drug contractors.—Ed. M. P. & C.]

### ABUSE OF RED TICKETS.

WHAT is my best course to pursue under following circumstances? A policeman brings in a red ticket to visit a man four miles distant when he had his leg broken, but tells me you will be paid all right as he is a shopkeeper, living fifteen miles distant, and had no money with him, so he got a ticket from the relieving officer. I attend him and send him home, having been assured by him that he would pay me, though, of course, he never did so. I intend having the ticket cancelled at next committee meeting, and would be glad to know if my proper course then would be to summons the patient for my fee, and also if the production of the cancelled ticket in court will be sufficient without employing a solicitor.

[Sue the patient at Petty Sessions, after having had ticket cancelled. The production of the ticket, with proof that the patient is not a "poor" person within the meaning of the Medical Charities Act, ought to be sufficient without solicitor's services.—Ed. M. P. & C.]

### THE CERTIFYING OF LUNATICS.

In an editorial note last week we referred to what we might call the abuse of the Dangerous Lunatics Act, by which that law is frequently employed as a means of obtaining speedy and gratuitous admission to the district asylum, although the patient is not, in any true sense, dangerous. The subject is referred to by Dr. Oscar Woods, the resident medical superintendent of the Killarney Asylum, in his latest Report to the governors, and we think his remarks appropriate and worthy of quotation as a corollary to our own observations. He says:—

"In my Report of last year I referred to the large number of patients that were committed as dangerous and criminal lunatics. Since then I have inquired more fully into the working of the Act 30 and 31 Vic., c. 118. I find that fourteen of the Irish superintendents in their

answers to the Poor Law Union and Lunacy Inquiry Commission condemned this mode of admission. Most people, I believe, look on this as the proper, certainly the easiest mode of admission, whereas the Legislature intended that it should be but seldom resorted to. Of the patients admitted into Irish Asylums in 1879, 1,277 were committed as dangerous and criminal. Dr. Hancock, in one of his late reports, which he kindly sent me, says that only three patients were committed as dangerous lunatics in England and Wales in 1877, as contrasted with 1,204 committed to asylums in Ireland, and this, notwithstanding that the Irish Act is drawn up on the lines of the English one. The reason of this is that there is too great a delay necessitated by the *ordinary application form* in use in Ireland. In England this form is not used, but a magistrate is empowered, on the certificate of a medical man that the patient is insane, to commit him to an asylum. The inspectors in the Annual Reports for 1874 and 1877 draw attention, in forcible language, to the great abuse of the Criminal Warrant. The following are a few of the inconveniences caused by this form of admission:—Nervous and diseased patients are handed over to the care of the police, and in many instances their recovery is considerably retarded thereby; the patient is branded as a criminal through no fault of his own; it is impossible to obtain any reliable information respecting the patient, the accompanying police knowing nothing whatever about him, as he has only been in their charge for a few hours, and the friends seldom, if ever, come with the patient to the asylum, the medical officers are thus in the dark for several days as to how to treat the patient. No one is responsible for the filling up of the forms, and they are usually most inaccurately and imperfectly filled; rarely are *facts observed* by the examining medical man stated. Lord O'Hagan during the Session of 1879 introduced a Bill 'to extend to Ireland the provisions of English Law as to neglected Lunatics,' and only withdrew it to await the report of the Poor Law Union and Lunacy Inquiry Commission. The necessity for the Bill has, I believe, been long felt, and it will, I hope before long be passed into law."

#### WELL-TO-DO PATIENTS IN DISTRICT ASYLUMS.

At the last meeting of the Limerick grand jury, Mr. Lyons said he would like if the grand jury also directed their attention to the several large sums applied for in connection with alterations in the Limerick District Lunatic Asylum. Within the last two years over £13,000 had been borrowed for the purpose of making alterations in the buildings and increasing additions to them. He thought it would be very well for the committee to call the attention of the governors of the asylum to that enormous outlay.

Mr. O'Brien begged to call the attention of the committee to a fact that turned up at a meeting of the governors when he had been on the board. Accommodation was very badly wanted, and the governors thought to make the relations and friends of a number of incurable and harmless patients that were in the hospital remove them, in order to make room in the asylum, and save the county from the expense of keeping them. But when the governors went to examine the matter they found that the orders laid down by the Privy Council, or some body which had control over the places, had been such that the governors had no power to compel the friends of the patients to take them back. He did not know whether that order was still in existence, but if so it would be well for the committee who might consider the matter, to take it into consideration. When once a patient was sent into the asylum it was difficult to put him out again. For the past years there had been a great increase in the number of inmates, and

the present amount of accommodation was not at all too much.

Mr. Delmege said he would like to direct the attention of the committee to another fact, that of persons getting into the asylum as paupers who were well able to pay for their support. He himself had discovered a patient in the asylum who was the wife of a farmer that had been actually supplying the workhouse with milk, yet he had his wife there, though well able to pay for support.

The matter was then referred to the committee.

#### SLIGO UNION.

##### BEEF TEA A DRUG.

THE Local Government Board wrote in reference to a communication received from the guardians, stating that it was their intention, when they proposed that Liebig's essence should be kept in the dispensary, that it was to be dispensed as a medicine. The Local Government Board failed to see how nourishment could be made a medicine. Beef tea, they said, could only be given in the ordinary way under the Poor Law Act.

The Chairman considered it was a mistake to call Liebig's essence nourishment. They wanted to give it as medicine.

Mr. Higgins—But is it not given as nourishment?

Mr. Collery admitted it was, but the doctors were to be called on to administer it as medicine—just as brandy and wine were given.

The Clerk said brandy and port wine were given under the Poor Law Act, to dispensary patients, through the relieving officers.

Mr. Collery—I do not see the difference between a doctor ordering beef tea and a dose of salts and senna (laughter).

Mr. Lyons—But the effect would be very different (laughter).

Chairman—But this beef tea is allowed to be given in other places.

Mr. Collery—And it must be given as medicine, for it is the doctor who orders it.

Mr. Cogan—He orders gruel, too, and it is not considered medicine.

Mr. O'Brien—Or a leg of mutton.

Mr. MacGill—We might as well call a beefsteak medicine.

Mr. Hunter—We can only give this beef tea through a relieving officer.

Clerk—But the guardians' object is to get half the price of Liebig's essence by using it as medicine.

Mr. O'Brien—I believe it was not the doctors who suggested this thing.

The Chairman believed it was.

It was agreed to again inform the Local Government Board that it was as medicine this beef tea was to be used, and to tell them that it was so given in other unions.

#### A THY UNION.

##### SANITATION.

DR. DARBY, Medical Officer of Health for the Monasterevan dispensary district, called the attention of the guardians to the state of Drogheda Row, Monasterevan, and stated that twelve months ago he reported the matter, and that since the passing of the Public Health Act he had called attention to it three times. He also called attention to a gullet, which was the only means of preventing the houses of the poor being flooded. He had repeatedly written to the late clerk on the matter, but his letters were never laid before the board. In conclusion, Dr. Darby said typhus fever had now broken out in the Row, which he never knew to be in so unsanitary a state as it is at present.

The sanitary sub-officer for Monasterevan, in reply to the chairman, said nothing could be done to remedy the evils complained of by Dr. Darby, until means were devised to carry off the water. The people's houses were in a very bad state.

It was ordered that the sanitary sub-officer consult with the Medical Officer of Health as to the best means of abating the nuisance, and to have his suggestions carried out forthwith.

#### GRAND CANAL STREET DISPENSARY, DUBLIN.

THE election of medical officer for the Grand Canal Street Dispensary was concluded last week, the successful candidate being Dr. C. B. Ball, who obtained 38 votes. The voting for the other candidates was as follows:—

J. Barton, 32; J. D. Mullen, 31; J. K. Denham, 29; J. D. Pratt, 29; F. T. Porter, 28; David E. Flinn, 17; Robert B. M'Vittie, 9; George B. White, 5; H. J. Ingham, 4; R. N. Lyon, 3; W. Beatty, 1; B. F. Knight, 1.

#### KANTURK UNION.

AT the meeting of the Guardians of the Kanturk Union, the election of medical officer to the house, rendered vacant by the resignation of Dr. James P. O'Shaughnessy, was proceeded with. Mr. Daniel M'Cabe proposed the reduction of the officer's future salary from £130 to £90 per annum.

The Chairman would not express an opinion as to the justice of the proposed reduction, but would say there was no necessity for putting or discussing the notice of motion, because even though Mr. M'Cabe succeeded in carrying it, it would not, in his opinion, affect the present election or the position of the doctor. They could not get over the fact that the board had advertised for a doctor at a certain salary, to be appointed that day, and any ruling the sitting board would make as to salary could not interfere with the action of the last board (hear, hear).

On a division there voted—for the proposition 6; against it, 25.

The greatest excitement was evinced in the result of this election, as evidenced by a crowded room, one of the candidates being Dr. Barry, son of the late Dr. Barry, visiting physician to the house for 41 years; and the other Dr. Lebane, nephew of Mr. M'Cabe.

Mr. M'Cabe subsequently announced his nephew had withdrawn from the contest, he having obtained a more lucrative situation elsewhere.

Dr. Barry was then declared duly elected by the chairman.

Mr. Harding, J.P., Charleville, begged to move the following resolution—"That this board cannot pass over the resignation of Dr. O'Shaughnessy, their late medical officer, without expressing their regret on the event, and assuring him that he has merited their earnest thanks and gratitude for his kind and skilful treatment of the numerous sick in this workhouse since his appointment. The board wish Dr. O'Shaughnessy every success in life, and are sure he will reflect, in any new sphere he may be placed in, credit and honour on himself, and distinction on the profession to which he belongs, of which he is a zealous and competent member.

The resolution passed unanimously.

#### SANITATION IN IRELAND UNDER THE GUARDIANS AND LOCAL GOVERNMENT BOARD.

Excerpts from Registrar's Notes for the Past Quarter.

**ANTRIM; Crumlin.**—This district has been remarkably during the last quarter. Inflammatory sore

throat has been rather prevalent within the last month of a diphtheritic character, wanting, however, in the depression and prostration of strength which distinguishes the latter, and with little or no exudation, but still decidedly infectious, as in the instance of one family who received the infection from a casual visitor; when four or five of the members had more or less mild attacks—one only (the mother) suffering acutely, and with a tedious convalescence.

**TANDERAGEE.**—The sanitary condition of this district was most satisfactory up to the 10th December, but since that date about one hundred cases of enteric fever have occurred. I assign the epidemic to the pollution of one of the principal water supplies of the town with typhoid sewerage. This well was the source from which the employees in the Tanderagee Spinning Mill obtained their drinking water. All the cases which occurred during the first fourteen days of the epidemic were clearly traceable to this source; but since that period other centres of contamination are evident. The type of the epidemic is mild, as a rule, although cases of extreme virulence have occurred. Every sanitary precaution is being taken to check the spread of the fever, and provision is being made for the relief of those suffering from it. The dispensary duties have so increased that it has been found necessary to appoint a second medical officer to the district.

**DUNGANNON.**—District healthy; typhoid fever has disappeared since the old pumps in the town have been closed, the water from which was very impure.

**KILKEEL.**—Five cases of diphtheria died out of a total of nine cases which occurred in this district. All of them were in houses situated in low, damp, and ill-drained positions; and were in all cases fatal within eight days.

**AGHALEE.**—During the past quarter there have been two cases of fever and several of simple continued fever. Two deaths are registered as resulting from diarrhoea. The district otherwise very healthy. Sanitary condition of the district rather defective, the inhabitants in a good many cases being unwilling to make any improvement.

**MAGHERAFELT; Magherafelt, W.**—District healthy. No epidemic.

**MONEYMORD.**—The sanitary condition of the farmers' dwellings is passable, but the arrangement of their cottiers' houses are very unhealthy from overcrowding, bad ventilation, want of light, dampness, &c.

**ULLID.**—I again direct attention to the unsatisfactory sanitary condition of the village of Mooncoin.

**WATERFORD.**—I attribute the high death-rate to the cause already frequently pointed out in my reports, namely, the wretched unsanitary condition of the poor and their dwellings.

**CLASHMORE.**—Sanitary arrangements are at a standstill. No decided advance towards a better state of things is reasonably to be looked for, while the habitations of the labouring class, instead of being homes for the people, are a public danger.

**BANDON.**—Having ascertained that two fatal cases of typhoid fever occurred in one of a row of six houses lately erected in a very elevated situation at an out-part of the town, I inspected all the houses, yards, and surroundings, which were perfectly clean, but I discovered that the water-closets of all emptied into a large underground closed-up receptacle for the entire, and no possible escape for the excrementitious exhalations, but back into the houses through the water-closets. This on representation to the Sanitary Board is in process of correction.

**CARRIGALINE.**—Scarlatina has been epidemic here for the past four months; it is now nearly gone. The sanitary state of the town is not so good as it ought to be; it is very difficult to get the yards of small houses (where two or more families reside) kept clean. I forward notices regularly to the Sanitary Board, but it is difficult to get much done.

(To be continued.)

# IRISH POOR-LAW INTELLIGENCE.

## NOTIFICATION OF INFECTIOUS DISEASES.

THE following important petition has been presented to the House of Commons by the Irish Medical Association :—

*To the Honourable the Knights, Burgesses, and Commons in Parliament assembled.*

The petition of the President and Council of the Irish Medical Association humbly sheweth :

That your petitioners are the executive of an association devoted to representing the opinions and interests of the medical profession in Ireland, and includes amongst its members a large proportion of the legally qualified medical men in practice in Ireland. That your petitioners have fully considered the notification of Infectious Diseases (Ireland) Bill now standing for a second reading in your honourable House, and have obtained the opinion of a large majority of the medical practitioners of the city of Dublin upon the chief proposals contained in said Bill, which opinion has been expressed by a majority of nearly two to one against any proposal which would require the medical attendant to notify in writing the occurrence of infective disease either to the sanitary authority or to the house occupier.

Your petitioners confirm the opinion thus expressed, and consider that the provisions of said Bill are not calculated to effect with certainty the discovery of infective disease in those instances in which concealment is most probable, while they will, if passed into law, impose upon the medical profession new functions inconsistent with the efficient performance of their duties towards their patients, and seriously prejudicial to their interests as practitioners.

That your petitioners apprehend that if, as would occur under the operation of said Bill, the visit of the physician be followed by the immediate enforcement of sanitary precautions, a great inducement will be created, in all instances in which it is desired by the house occupier to avoid the application of the sanitary law, to omit sending for a medical attendant, or to defer doing so until the disease had reached a stage in which its treatment would be difficult and ineffective. Your petitioners, therefore, anticipate that the number of undetected cases of infective disease might rather increase than diminish under the operation of the proposed law, while in many instances the chances of restoration of the patient to health would be greatly prejudiced.

Your petitioners humbly submit that the professional and monetary relations existing in Ireland between the physician and his patient are altogether different from those which exist in other divisions of the kingdom, and furthermore, that the methods of application of sanitary law in Ireland are not fairly comparable with those

which exist elsewhere ; and your petitioners therefore submit that a system of notification of infective disease applicable to England and Scotland may prove altogether unsuitable to Ireland, and they are of opinion that any enactment which requires the medical attendant in Ireland to give a written certificate of the disease from which his patient is suffering will be inoperative in many instances, and will tend to increase the evil which it purports to remedy.

Your petitioners are furthermore strongly of opinion that in respect of the fee proposed to be paid for such notification, the penalty imposed for omission to notify, and in other details, the said Bill is altogether objectionable.

Your petitioners, therefore, humbly pray that your honourable House will not pass said Bill.

(Signed) J. CHAPMAN, President.  
R. BROWNE, Hon. Sec. of Council.

## LIST OF ENTRIES IN THE REGISTER OF THE BRANCH MEDICAL COUNCIL (IRELAND) FOR THE MONTH OF MARCH, 1881.

- MARCH 1st.—Phillips, William ; Woodbrook, Portarlington, Queen's county ; Lic. Fac. Phys. and Surg. Glas. 1880.  
7th.—Smith, Michael ; Castlehill, Ballyrooy, co. Mayo ; Lic. R. Coll. Surg. Irel. 1879, Lic. Apoth. Hall Dub. 1879.  
8th.—Patterson, George de Joncourt ; Islanderry, Dromore, co. Down ; M.B. 1880 and B.Ch. 1881 Univ. Dub.  
8th.—Moore, Thomas Charles ; Middleton College, co. Cork ; M.B. 1881 and B.Ch. 1881 Univ. Dub.  
8th.—Gordon, William Spear ; The Elms, Blackrock, co. Dublin ; M.B. 1880 and B.Ch. 1880 Univ. Dub.  
9th.—Cockle, Austin John ; 17 Palmerston Road, Dublin ; M.B. 1880 and B.Ch. 1881 Univ. Dub.  
11th.—Brook, James Stuart ; Company's Agent, East Indian Railway Company, Calcutta ; Lic. R. Coll. Surg. Irel. 1880, Lic. K. Q. Coll. Phys. Irel. 1881.  
11th.—McKee, James Charles ; Crossnamuckly, Newtownards, co. Down ; Lic. R. Coll. Phys. Edin. 1881, Lic. R. Coll. Surg. Edin. 1881.  
23rd.—Studdert, Richard Charles ; 17 Merrion Square East, Dublin ; M.B. 1880 and B.Ch. 1881 Univ. Dub., Lic. Mid. K. Q. Coll. Phys. Irel. 1881.  
24th.—Thunder, Edmund Joseph ; 6 Upper Mount Street, Dublin ; Lic. R. Coll. Surg. Irel. 1877, Lic. 1881 and Lic. Mid. 1881 K. Q. Coll. Phys. Irel.  
26th.—Dennis, Ffolliott Reginald ; Milltown Pass, Killucan, co. Westmeath ; Lic. R. Coll. Phys. Edin. 1879, Lic. R. Coll. Surg. Edin. 1879.  
29th.—Scriven, George ; 33 Stephen's Green, Dublin ; M.B. 1880 and B.Ch. 1881 Univ. Dub.

MEMORANDUM, 31st March, 1881.

The following names have been erased from the Register of

the Branch Medical Council (Ireland) during the month of March, 1881, pursuant to the 14th Section of the Medical Act, no reply having been received to several letters of application, or as having been reported dead or ceased to practise, viz.:-

Carey, Thomas; Limerick. Dead.  
Henev, Thomas Henry; Bathurst, West Africa. Dead.  
Price, John Roberts; 15 Upper Mount Pleasant Avenue, co. Dublin. Dead.  
Taylor, Adrian; Kenmare, co. Kerry. Ceased to practise.

### SLIGO UNION.

#### LIEBIG'S EXTRACT AS NOURISHMENT.

THE Local Government Board wrote in reference to the proposal to give Liebig's extract of beef as nourishment, and to leave pots of it in dispensaries as medicines, as follows:-

This cannot be legally administered as medicine by the medical officers, and any expenditure incurred for such a purpose would, consequently, be liable to disallowance by the auditor. The only manner in which legal effect could be given to the views of the guardians in the matter would be to recommend relieving officers to be guided, so far as possible, in the exercise of their powers under section 7 of the Poor Law Relief Extension Act, by the advice of the medical officer as to the most suitable form in which out-door relief by way of food should be administered to dispensary patients.

#### THE MEDICINE CONTRACT.

The Local Government Board directed the guardians' attention to the following extract from Dr. Roe's quarterly return, relating to Carney (No. 1) district:-"Great trouble given by contractor not sending the quantity ordered. Cannot say the medicines are of good quality—I should say inferior."

Mr. Higgins—I knew there were some complaints before from Dr. Roe.

Mr. Rowlett—Did any other of our dispensary doctors complain?

The Clerk did not know of any.

Mr. MacGill thought it strange that only one doctor should complain of the medicines.

Mr. Brennan—It proves Dr. Roe is doing his duty.

Mr. Walker did not look on it in that way. There were as good doctors in the Sligo dispensary district as there were in the union, and yet no complaints were made by them.

Chairman—It is better to let those who will select the medicine contract consider this letter.

Mr. Rowlett was for further inquiry. He considered Dr. Roe should point out in what particular the medicine contractors failed to discharge their contracts.

After some further discussion the matter was left over, as the contract for medicine was to be considered.

Messrs. Leslie were again declared contractor for medicines and medical appliances.

#### THE WHOLESALE ISSUING OF DISPENSARY TICKETS IN COLLOONEY.

The following letter was read:-

Collooney, March 7, 1881.

Sir,—With reference to the resolution passed by the Collooney Dispensary Committee, at their meeting on February 1st, 1881, directing their medical officer "not to act on any ticket not duly filled up and signed personally by the party authorised to do so," I beg to state that a similar resolution was passed by the Collooney Dispensary Committee on the 17th September, 1858, and again on June 2nd, 1873. During my first year of office in Collooney, the number of tickets issued was 1,520, more than half of that number being issued by deputy. The

second year (1880) the number rose to 1,742, nearly 1,300 of that number having been issued by persons not legally authorised to do so. The Local Government Board having asked for an explanation from the committee, the matter was considered, and the resolution above referred to was passed. In Sligo dispensary district, with four times the population of Collooney, with two medical officers and an apothecary to discharge the various medical duties of the district, the number of tickets issued is some hundreds below the number received by me. There has been no epidemic in the district of any kind that can account for the increase in the tickets. That the committee was not exceeding its duty in passing the resolution, nor do I infringe the rules of the Local Government Board when I refuse tickets not legally filled up, the accompanying copy of a circular will testify.

I am, sir, yours faithfully,

JOHN MOLONEY.

Mr. Maguire—That must have only reference to the district about Collooney, for in our district no such tickets are issued.

Mr. G. Simpson said that, as new dispensary committees would be shortly elected, it should be made a rule to knock off members who issued tickets in this way.

Several guardians said that with many it was the practice to sign a book of tickets and leave the blanks to be filled up when an applicant called in their absence.

Chairman—That is not fair.

Mr. Maguire—I know this much, that Dr. Moloney is trying to do his duty. I knew him to visit poor persons without a ticket at all.

Chairman—I always find him most attentive to his duties.

Mr. M'Loughlin—There could be no better man.

Chairman—What should we do now? It does seem a hardship on the doctor, and the dispensary committee declare it so.

Mr. Collery—But the board of guardians refused to adopt the resolution of the dispensary committee, and declined to give the doctor the discretion of attending on a patient or not as he liked. It was left to himself to take what action he pleased.

Mr. Maguire considered he would have a good cause of action if he attended a person on such a ticket who was not properly entitled to medical relief.

Mr. O'Brien—What is to be done if a man has to go away from home—to attend the assizes, for instance? Surely he should have the power to leave a few tickets after him signed for the convenience of the district. Perhaps a person may die for want of medical attendance if a ticket could not be procured.

Mr. Walker was sure there was no fear of that, for under such circumstances the clergyman of the parish could be appealed to, and a note from him would soon secure the doctor's attendance.

Mr. Maguire—And if one member of the committee is away others will be at home.

Mr. Walsh—I find some doctors will only attend once on a dispensary ticket, no matter if the patient requires a second visit.

Mr. G. Simpson—That is not the practice in our district, for the Riverstown doctor attends on the one ticket till the patient is—

A Guardian—Killed or cured.

Mr. Walsh—I know it is the practice in Sligo for a doctor to require a second ticket before he pays a patient, no matter how sick he is, a second visit.

The matter was referred to the dispensary committee

#### THE MEDICINES.

The Clerk reported that Dr. Roe, of Carney district wished that the medicines forwarded to him by the Messrs. Leslie should be analysed.

Mr. Collery considered it was only right that Dr. Roe's request should be acceded to.

Chairman—Certainly ; if he still adheres to his opinion he should be satisfied.

Mr. Brennan—He proved to us before he had good reason to complain of some of this medicine.

Chairman—He ought to specify what medicines he thinks are inferior.

Mt. Colliery said that when the contact for medicines was being last taken he and Mr. Nelson went over the list sent in by the contractors who tendered, and it was most extraordinary to see the difference in prices between some of the tenders. In some cases where the Messrs. Leslie charged only 6d. or 1s. the others charged 5s.

Mr. Walsh—Let Dr. Roe now pick out the medicines he thinks are not of good quality, and let them be analysed. I know he complained of certain medicines before when he wrote to the board on the subject.

Mr. Brennan—He showed where a spurious sort of medicine was sent in place of what he ordered.

Chairman—I think we should call on the doctor to specify some particular medicine.

Mr. Walsh—Let him supply a list of those he thinks are inferior.

Mr. Brennan—He also complained of being short of some medicines.

Mr. Colliery—There were about thirty medicines in the list. He should be asked does he mean all are of inferior quality, or will he be satisfied to have three or four of them tested.

The Chairman considered it would be unfair to ask the County Analyst, who only got a small salary, to analyse all the medicines. A few as a test, should do.

Mr. Walsh—I am of opinion he only complains of a few medicines.

The Clerk was directed to write to Dr. Roe, and the matter dropped.

### TRICHINOSIS.

THE following circular letter was transmitted last week from the Local Government Board to the clerk of each union in Ireland :—

Local Government Board, Dublin,  
23rd March, 1881.

SIR,—The Local Government Board for Ireland desire to state that their attention has been called to the disease which has been attributed to the consumption by human beings of the imperfectly cooked flesh of pigs infested by the worms known as Trichinae, and other similar parasites.

Some very serious diseases in man, of which the chief is named trichiniasis, result from eating the flesh of pigs that have become infested with minute parasitic worms.

It is upon the imported flesh of foreign pigs that suspicion of being thus infested has recently fallen ; but it will be prudent to regard all pigs as liable to parasitic disease, and to remember that the influence of it upon the animal is not nearly so evident as when the disease attacks man.

Under these circumstances the Board think it prudent that special precautions should be taken in regard to this matter, particularly where foreign pork and bacon are concerned ; and they wish to point out that the only known means of avoiding disease in man from this dangerous quality of meat from pigs is by very thorough and effective cooking. To be efficient for the required purpose, the cooking of pork, of hams and of bacon, should be prolonged for about half as much time again as is customary ; the smallest joint should be cooked for not less than an hour, and whatever be the size of the joint, it should not have less than half an hour's cooking for each pound of meat. But, if there is reason for thinking that a particular sample of meat contains the parasites, it ought not, on any account, to be eaten, no matter how it is cooked.

The Board would also remind the Sanitary Authority

of the powers which they possess under sections 132 & 136 of the Public Health (Ireland) Act, 1878, in relation to the sale of diseased, unsound, or unwholesome meat ; and to suggest that the Sanitary Authority should employ their Medical Officer of Health, and Sanitary Sub-officer, to use special vigilance in carrying out the provisions of those sections in relation to the descriptions of meat referred to.

By order of the Board,  
B. BANKS, SEC.

### DISEASED MEAT.

At the Enniskillen petty sessions recently, the Local Sanitary Authority had summoned a man named M'Kigney, for offering for sale in the Pork Market two pigs which were unsound and unfit for human food. Mr. Dundas, sub sanitary officer, proved that his attention had been directed to the animals, and, having seen them, he found they were unfit for human food. He informed Dr. Gamble, who went and saw the animals, and gave a certificate that they were unsound. Dr. Teevan, J.P., afterwards, on the production of the doctor's certificate, gave an order for their destruction. The animals were buried, and the owner of them summoned. The majority of the bench construed the Act to imply that the magistrate himself should have seen the animals before giving the order for their destruction. Mr. Wray read the section (33), and contended that the case might be dealt with either by the justice who saw the animals, or any other justice having jurisdiction. As the bench had a doubt as to the interpretation that should be put on the Act, it was allowed to stand over for opinion of the Law Adviser.

### ALLEGED CONCEALMENT OF DISEASE.

LAST week, Dr. Burke, Local Government Inspector, held an inquiry, at the Bailieborough Union, into the conduct of Dr. Clarke, dispensary doctor, and Mrs. Lancashire, a lady of property in the neighbourhood.

Mrs. Lancashire was charged with bringing a case of typhoid fever to the district.

Dr. Clarke stood charged with co-operating with Mrs. Lancashire.

The evidence went to show that on the 17th November last Mrs. Lancashire had a son in the employment of Mr. Acheson, Portadown, and this lad being affected with typhoid fever was sent home by his employer. It appeared that Mrs. Lancashire, who lived in a cottage between Cootehill and Bailieborough, about a mile outside the latter town, sent a carriage from Bailieborough to meet her son at Cootehill station. When the vehicle returned to the avenue that leads to Mrs. Lancashire's house, she stopped it and refused to admit the diseased boy to her house. Mrs. Lancashire is the landlady of house property in the town of Bailieborough. To one of these houses, a portion of which is unoccupied, the boy was sent by the order of his mother, and it was alleged upon the advice of Dr. Clarke, he was to remain there until he had recovered. These premises were let and sub-let, and were the abodes of several parties. When it became known that a case of typhoid fever was in the town, Dr. Clarke, who is also local sanitary inspector was noticed by a number of citizens to have the boy removed to hospital. Dr. Clarke paid no attention to the notice. Mr. Cooke communicated with the Board of Guardians, but notwithstanding this, it was alleged that the epidemic was permitted to spread.

After hearing the evidence, Dr. Burke said he would submit it to the Local Government Board, and that they would receive the decision of that body after the circumstance was considered.

## SANITATION IN IRELAND UNDER THE GUARDIANS AND LOCAL GOVERNMENT BOARD.

*Excerpts from Registrar's Notes for the Past Quarter.*

**CORK.**—There has been an increase in the number of cases of typhus fever, amounting nearly to an epidemic, during this quarter. The only cause assignable is the late dry, warm, autumn, and the overcrowded lanes in the urban portions of the district and the deplorably dirty habits of the people living in these lanes.

**ANASCAUL.**—Fever has occurred in eight families in the village in which it was prevalent during the summer months. The people of this locality are particularly negligent in carrying out any sanitary regulations.

**GOLEEN.**—It would be impossible that the sanitary state of the district could be worse. The surroundings of some of the drinking wells are disgusting to sight, offensive to smell, and the water is so polluted that in my opinion it is totally unfit for domestic use. The sewerage in the villages is extremely bad, and there are no privies attached to the houses, consequently the public streets are used for private purposes. The poor people surely have very bad dwellings, totally unfit to lodge even the lower animals much less human beings. A great deal of this is caused by poverty, yet improvements could be made, and for a very small public outlay, we could have good sewerage, and good and unpolluted water.

**BALLINA ; Crossmolina.**—There is an outbreak of whooping cough, but none of the cases have, up to the present, proved fatal. The district is free from disease except the above-mentioned. The sanitary laws in most cases are well attended to.

**IRVINESTOWN.**—I had seven cases of typhus in hospital from one house in the Ederney district in this union, all of whom recovered. The medical officer reported the unsanitary state of the place, and the guardians took the necessary steps to remedy it. No other case has occurred in the locality since, and I think the case is one clearly caused by the filthy condition of the house.

**BURT.**—The condition of many of the houses of the poor is by no means conducive to the successful treatment of whooping-cough, particularly when complicated with severe bronchitis. The occupants of these houses are badly protected against the severity of the weather. In some cases the wind gains easy access through the doors and windows, and the rain finds entrance through parts of the roofs, so that it is sometimes necessary to shift the beds to another part of the house to prevent the drops of water from falling on them.

**MANORHAMILTON.**—I brought before the Sanitary Board lately the fact that a pump should be placed over one of the wells in the town, but after passing a resolution to have a pump erected, one of the guardians at a meeting held since, proposed that the former resolution be rescinded, which was done.

**CAVAN ; Killeshandra.**—One widow of a labourer died of apoplexy, aged 105 years. The wretched sanitary condition of the town of Killeshandra has been frequently brought under the notice of the sanitary authorities I have recommended new sewers, and were it not for the natural healthy situation of the town we would never be free from fever and other infectious diseases, the result of filth, bad sewers and stench.

**MOHILL.**—Typhoid fever has been prevalent in the town of Mohill, and in some parts of the rural district during the quarter ; nine of the deaths registered were caused by it. I consider the outbreak in Mohill due to defective sanitary arrangements in the first instance, and also to the apathy and indifference shown by the

relatives of those afflicted in not calling in medical aid in time, and in not having the cases isolated from the rest of the family in the early stage, by removal to hospital. I may further add that the barbarous habit of waking the dead, which still exists, has had something to do with spreading the disease, as I distinctly traced the illness of an entire family to the fact of one of its members having attended the wake of a party who died of typhoid fever, where he caught his disease, from which they all subsequently suffered. I may observe with respect to the defective sanitary arrangements, that though my reports and suggestions have been to some extent carried out by the sanitary authority, yet still much remains to be done.

**KILLERORAN.**—The supply of clothing was the best disinfectant we have had. When we commenced distributing the bed clothes we had forty cases of fever, and the last case reported was in October last. There are other sanitary measures much required in the district ; if any possibility of carrying them out will show itself, we will be happy to suggest the remedy, but at present the hope of using them is remote.

**LOWPARK.**—The sanitary state of my district generally, but especially of Charlestown, is in a most defective condition. Last year there was an epidemic fever, and I very much fear its recurrence, unless precautionary measures are adopted. I am making a general inspection of the town with a view to a full report, but since my appointment have been so inundated with red tickets, that I have not had time to complete it yet. There are but two privies in the street where I reside, and no sewerage of any kind ; the smell sometimes, even in my own house is I have no doubt, sufficient to cause disease. During a recent inspection I saw lime which was given out for the purpose of whitewashing, when the fever was prevalent, lying unused in some of the houses.

**LOUISBURGH.**—The present satisfactory condition of the public health has been brought about chiefly by the improved circumstances of the people as to food. I regret that I cannot anticipate being able to make an equally satisfactory return next quarter, there being in the district a great number of persons who have failed to make sufficient provision for their maintenance during the spring and early summer.

**KILMACTHOMAS.**—I regret to say that the sanitary law is but very spasmodically and ineffectually put in force by the Sanitary Authority. The wretched state of the cabins occupied by the agricultural labourer is deplorable in the extreme. Manure heaps and cesspools, bad roofs, allowing the rain to come in, want of separate sleeping accommodation for the sexes. These are some of the many evils which contribute so powerfully to the social and moral degradation of our poor people, and which, I trust, a wise legislature will endeavour to remedy by compelling owners of land to keep suitable abodes (at least wind- and water-tight) for the use of the agricultural labourers. The water supply in the village of Newton, alluded to in my last report, is still deficient. Two remarkable cases of longevity occurred during the quarter, one old man being 106 years, and another 112. Making allowance for exaggeration, they must have been, indeed, very old, one of them having taken an active part in what he called the "risin," or the rebellion of 1798.

**TRALEE.**—Eighteen cases of fever came under my notice during the quarter. Five deaths from it were registered. I cannot say much for the sanitary improvements. About twelve months ago I drew the attention of the authorities to the wretched crowded habitations of the labouring classes, badly constructed houses with filthy back-yards, many of them mere cess-pools. I also reported on the vile habit of slaughtering animals in dwelling-houses, and on the general want of drainage in the town ; these nuisances are still in existence.

# IRISH POOR-LAW INTELLIGENCE.

## THE LUNACY LAWS ASSIMILATION (IRELAND) BILL.

THIS important measure, intended to extend to Ireland some provisions of English and Scotch law as to the care of lunatics, has been introduced by Mr. Litton, M.P., Mr. Findlater, M.P., and Sir Thomas M'Clure. It is practically the same as Lord O'Hagan's Bill of 1879, which got its second reading in the Lords, but which Lord O'Hagan did not proceed with, as he became Lord Chancellor for Ireland shortly afterwards, and its object is fourfold :—

1. To provide for the boarding out of harmless lunatics, so as to relieve the asylums, and thus make room in those institutions for curable cases.
2. To enable lunatics in the incipient stage to be sent to asylums before the malady has become confirmed, and before the lunatic has become so intent on committing a crime as to be brought under the operation of the Dangerous Lunatics' Acts.
3. To provide for periodical supervision of those "boarded-out" lunatics by the dispensary medical officer of the district, in order that their proper and orderly maintenance may be ensured.
4. To give power to the guardians to vote outdoor relief to a family when one of its members is a lunatic or idiot, the existing power being restricted to the head of the household.

This fourfold object the Bill seeks to achieve by extending to Ireland the provisions of sections 66 to 68, both inclusive, and of sections 70 to 72, both inclusive, and of sections 78 and 81 of the Act 16 and 17 Victoria, chapter 97, entitled "An Act to consolidate and amend the laws for the provision and regulation of lunatic asylums in counties and boroughs, and for the maintenance and care of pauper lunatics."

These sections are (in abstract) as follows :—

Every pauper lunatic not in an asylum . . . shall be visited once in every quarter of a year by the medical officer of the parish (dispensary district), and such medical officer shall be paid the sum of 2s. 6d. for each such quarterly visit to any pauper not being in a workhouse, which sum shall be paid by the same persons, and be charged to the same account as the relief of such pauper ; and within seven days after the end of every such quarter such medical officer shall prepare and sign a list of all such lunatics, and shall state therein whether any of such lunatics are or are not properly taken care of, and may or may not properly remain out of an asylum, and such medical officer shall deliver or send such list to the (inspector). . . .

Every medical officer who shall have knowledge that any pauper resident within the district is a proper person to be sent to an asylum, shall within three days give notice thereof to a justice of the peace, and thereupon the said justice shall require such relieving officer to bring such pauper before him, and the said justice before whom such pauper shall be brought shall call to his assistance a physician, surgeon, or apothecary, and examine such person, and if such physician, surgeon, or apothecary shall sign a certificate, and if such justice be satisfied that such pauper is a proper person to be detained under care and treatment, he shall direct such pauper to be received into the asylum.

Every constable and every relieving officer who shall have knowledge that any person wandering at large (whether or not such person be a pauper) is deemed to be a lunatic, shall immediately cause such person to be apprehended and taken before a justice, and every constable and every relieving officer who shall have knowledge that any person not a pauper and not wandering at large is deemed to be a lunatic, and is not under proper care or control, or is cruelly treated or neglected, shall within three days give information thereof upon oath visit to a justice, and such justice shall either himself and examine such person, or by an order under his hand and seal direct and authorise some physician, surgeon, or apothecary to visit and examine such person, and make such inquiry, and to report in writing ; and in case that such person is a lunatic, and is not under proper care and control, or is cruelly treated or neglected, it shall be lawful for such justice to require any constable or any relieving officer to bring him before any two justices, and the justice before whom any such person is brought shall call to his or their assistance a physician, surgeon, or apothecary, and shall examine such person, and make such inquiry relative to such person as he or they shall deem it necessary, and it shall be lawful for the said justices to direct such person to be received into such asylum as hereinafter mentioned.

If any medical officer omit for more than three days . . . to give such notice thereof as is hereinbefore required, such medical officer shall . . . forfeit . . . ten pounds.

If any relieving officer refuse or wilfully neglect to execute orders with all reasonable expedition, he shall forfeit . . . ten pounds.

Where application is made to the inspector by any relative of the pauper lunatic confined therein, requiring that he shall be delivered into the custody and care of such relative or friend, it shall be lawful for them, upon the undertaking in writing of such relative . . . that such lunatic shall . . . be properly taken care of, and shall be prevented from doing injury to himself or others, to discharge such lunatic.

It will be observed that the effect of these clauses is to provide—*a.* That all lunatics who are at large shall

be periodically inspected by the dispensary medical officer, and returns of their condition made to the inspectors, for which duty the officer is to receive a fee of 2s. 6d. a quarter.

b. That all medical officers, relieving officers, &c., shall be bound to give notice of the state of any person whom they may find to be insane, and that the person so reported shall be examined and certified in the same manner as dangerous lunatics are now dealt with. For the remuneration of the medical officer for performance of this duty, the Bill provides in the terms as follows :

The provisions of the fourteenth section of the Lunatic Asylums (Ireland) Act, 1875, as to the remuneration of medical officers, and payment of other reasonable expenses in and about examinations under that Act, shall extend to and apply to examinations, inquiries, and reports under this Act, other than quarterly visitations of pauper lunatics, and any justice or justices causing any person to be examined under this Act may make a like order, and the money so ordered shall be paid in like manner as orders made and moneys paid under that section.

### ABUSE OF DISTRICT LUNATIC ASYLUMS IN IRELAND.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In the *Medical Press* of the 16th inst., I have observed the proceedings of the Coleraine Board of Guardians respecting the grievance of a board of guardians being called upon to pay the fees to the medical officers for the examination of dangerous lunatics, in persons who were in good circumstances, and as there is some misconception on this point, I think it advisable to draw attention to the fact that the law amply provides against an imposition of the kind. The 16th Section of the 38 and 39 Vic., cap. 67, is as follows :—

#### LUNATIC ASYLUMS (IRELAND).

38 and 39 Vic., cap. 67.

Sec. 16.—Where any person shall be confined in any district lunatic asylum as a patient, it shall be lawful for a court of summary jurisdiction, in case it shall be proved to the satisfaction of such court, that such patient has an estate applicable to his maintenance, and more than sufficient to maintain his family (if any) by order to require the relation, or other, the person in receipt of the income of such patient, within one month after the service of such order to pay the charges, of the examination, removal, lodging, maintenance, clothing, medicine, and care of such patient, and within one month from the time in such order respectively specified to continue to pay, so long as such patient shall remain in such district lunatic asylum, and in case such charges shall not be paid within the times respectively prescribed, it shall be lawful for the resident medical superintendent of such district lunatic asylum to make such application under the Lunacy Regulation (Ireland) Act, 1871, to the Lord Chancellor of Ireland . . . as he may be advised to apply to the court of summary jurisdiction, and thereupon it shall be lawful for such court, on proof of the service of such order, and of the non-payment of such charges respectively in accordance with the terms of such order by an order to direct the superintendent, or an officer of such district lunatic asylum, to seize so much of any money . . . goods and chattels, and so take and receive so much of the rents and profits of the lands and tenements of such patients . . . as may be necessary to pay such charges.

I may observe that in 1874, the attention of Sir Michael Beach was prominently drawn to the very great abuse of persons with available means being treated as patients in district asylums gratuitously. And on these representations, the late Chief Secretary for Ireland adopted the principle of liability for maintenance in his bill, which soon after became law.

The question may reasonably be asked, is the law put into force, regarding that class who avail themselves of treatment in a district asylum, and who are properly made liable for the expenditure incurred? The attention of the inspectors of lunatic asylums to this matter is desirable with a view to checking this abuse, and thus lessen the burthen on both the ratepayers and the Government, who give a large capitation grant.

I am, yours, &c.,

OBSERVER.

26th March, 1881.

### BOYCOTTING BY RED TICKETS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—It has been said, "A rose by any other name smells as sweet," so I conclude "Boycotting" under any other form is just as bitter; and a form of it has long existed, and often been exposed in the pages of the *Medical Press and Circular*, where the dispensary medical officer has been Boycotted by unlimited abuse of red tickets, &c.; and though I have regularly studied your pages for nigh thirteen years, and read accounts of numerous, and often merely whimsical, reports of neglect, which showed the animus, if they had the opportunity, against medical men, which were duly received and examined into by the Local Government Board, I cannot remember a single case where the Board have interfered for the abuse of their authority by guardians and other members of committees—or, have the Board any power to interfere?

I believe I am—lately, especially—made a target for this sort of injustice by a few members of the now universal Land League, not having joined that aristocratic body, and having done some few acts not agreeable to them, they doubtless look on me as the wrong man in the wrong place, as, by a metamorphosed committee, and that freedom or control from their betters Mr. Gladstone is bestowing, they could now elect a man to their choice in political and religious sentiment, which is generally the necessary qualification for office. There are now four members (three of whom I have crossed during my term of office; the fourth is a relative) on the committee. One of them collected a large heap of offensive manure near my residence, which I had to get rectified. Another committed a grievous assault, and on my evidence was mulcted in £100 damages. The third I reprimanded for poaching on my premises. For these offences on my part, and other independent acts, I have received a red ticket brought to my house by the patient (this is not quite a new thing); I have also been supplied with a red ticket marked "urgent" for a case of sub-acute rheumatism I was in attendance on. I may say I have had tickets marked "urgent" for chronic cases before. The poor people stated afterwards they did not ask for the ticket, and would not have come for me so soon only it was brought to them, and they were told I would be made to go. I believe the reason it was issued was because I happened to be from home. The party refused to go for my substitute (I believe the issuer thought I had none), a few miles further, which did not exhibit much anxiety on their part. On my man driving for my substitute, and bringing him to the case, he has recorded his opinion there was no urgency in it. Doubtless this is only the commencement of a combined attack. Most of the other members have declined to join this league against me, but they will not attend, or take any part in redressing grievances, so I let them lie in abeyance at present. Although of such long

experience in discharging my duties, I should be glad of any advice you can afford, to try and rectify such matters, if such can be given—or is it “a disease past cure,” bred and born of the system of which the law, as at present, allows advantage to be taken.

Yours truly,

IGNORAMUS.

### THE LATE POOR-LAW INQUIRY AT BAILLIEBOROUGH.

THE Local Government Board have addressed a letter of which the following is an abstract to the Guardians of the Baillieborough Union :—

“SIR—The Local Government Board desire to inform the Guardians that they have received from their Inspector, Dr. Burke, his report of the inquiry respecting the cases of fever in the town of Baillieborough, and the apparent cause of the outbreak of the disease, and into the charge that Dr. Clarke co-operated with Mrs. Lancashire in placing her son, when suffering from fever in a house situated in the town, and occupied at the time by other persons.

“It appears from the evidence that Mrs. Lancashire was informed by telegram that her son, Heuston, was being sent home ill from Portadown, and not having sufficient accommodation in her own house she determined on placing him in an unoccupied shop on the ground floor of a house owned by her in Baillieborough, the upper part of which house was occupied by an Acting-constable and his wife; having so determined Mrs. Lancashire made arrangements for the conveyance of her son from the railway station. She proceeded with him to Baillieborough accompanied by Dr. Clarke—who in compliance with a request received from her that day had reached her residence at the same time as her son, and to whom she then communicated her intention of sending her son for treatment to Baillieborough. At this time Mrs. Lancashire was not aware of the actual nature of her son's illness, the disease not having sufficiently developed itself to enable Dr. Clarke to offer a decided opinion, but she ‘feared it would turn into fever,’ that disease being at the time prevalent at Portadown. Dr. Clarke pronounced the disease to be typhoid fever, and young Lancashire remained in the house during the entire course of the fever, which extended over a period of three or four weeks when it terminated in his recovery.

“Meanwhile, Dr. Clarke was served with notice requiring him to ‘have Mrs. Lancashire's son removed to the proper place for treating such contagious and dangerous diseases.’ He at once informed Mrs. Lancashire of this notice, but she refused to have her son removed stating that the house in which he was being treated was her own property and in her own possession and in submitting the case to the Guardians for their instructions Dr. Clarke was, it appears, informed by them that he had no power to interfere with Mrs. Lancashire in the exercise of her discretion; and here it is observed that in removing her son into Baillieborough for treatment in the first instance, Mrs. Lancashire most distinctly declares that she acted solely on her own responsibility. Her evidence generally, therefore, corroborated as it is by that of Dr. Clarke is, in the opinion of the Local Government Board, sufficient to prove that the latter did as alleged ‘co-operate with Mrs. Lancashire in placing her son when suffering from fever in a house occupied by other persons,’ and Dr. Clarke must therefore be held exonerated from culpability in regard to his action in the matter as medical officer of health.

“With respect to the alleged connection between the introduction of young Lancashire's case, and the subsequent outbreak of fever, the medical gentlemen examined

are unanimous in declaring that the defective condition of sewerage and water predisposed the inhabitants to suffer from typhoid fever.

“The Local Government Board feel therefore that they cannot too strongly impress upon the Guardians the great necessity of their immediately considering as to the best means of providing a remedy for these defects. The present would appear a most suitable season for the execution of such works as may be determined on for the purpose, and no time should be lost in the execution of the requisite preliminaries.

“You will be good enough to return the evidence when no longer required by the Guardians.

“By order of the board,

“B. BANKS, Sec.”

### SOUTH DUBLIN UNION.

DR. MACCABE, L.G.I., mentioned that the medical officer of the Meath Street Dispensary had complained to the Local Government Board of the condition of the premises. He had appealed to the Local Government Board to use their influence with the Board of Guardians, who are the custodians of the premises, and he thought as long as the condition of management required the medical officer to be resident, and that his family were there, the Board should see that the premises be not injurious to health.

Sir G. Owen said the premises were now under observation and were being looked after.

Mr. Shackleton said he was acquainted with the premises, and undoubtedly they wanted cleaning and painting, but if the place was gilt he did not think it would be suited to its purpose. As for its condition now, the house was wholly unfit for the business to which it was applied.

Mr. Callow, explained that the premises were about to be improved pending the selection of a site for a new building.

The following letter was received from Dr. George Owens :—

GENTLEMEN,—I beg respectfully to call your attention to the case of an inmate named Esther O'Neill, at present in the union. The facts of the case are as follows—She was admitted into this house some years ago, and during the past three years on several occasions did attempt to commit suicide. She was convicted before the magistrate of the offence, and she was also sent as a dangerous lunatic to the Richmond Asylum. She was discharged and sent under my care, I had her placed under strict observation, and I observed her getting into a dangerous form of mania. I thoroughly examined her and found she was a dangerous lunatic. I had her transferred to the lunatic department, where there is every accommodation for her, but Dr. Jennings refused to admit her, and on other occasions has done a similar thing. I submit for your approval what I have done, and ask you to advise what further steps I am to take.

I am, &c,

GEORGE OWENS.

After some conversation, it was resolved that Dr. Jennings be called upon to explain to the board why he acted as described by Dr. Owens.

At the following meeting of the board the clerk read a letter from Dr. Jennings in answer to the request of the board that he would let them know his reason for refusing to admit a woman named Esther O'Neill, who had on several occasions made attempts to commit suicide. Dr. Jennings said he had examined the woman. She had at intervals, during the many years she was in the house, shown a violent temper, but when she was sent to him by Dr. Owens she was not accompanied with any certificate of insanity. He (Dr. Jennings) considered she was per-

fectly rational, and being unacquainted with her history, he was of opinion that he should not consign her to a confinement amongst lunatics, and which he believed would have a most injurious effect on her mind, as the woman was of a very melancholy disposition, and suffered sorrow on account of her ill-spent life. This made her peculiarly unfitted for detention amongst lunatics. The Central Asylum should receive all dangerous lunatics, the work-house asylum being only intended for harmless imbeciles.

Mr. Shackleton had seen the woman, and thought Dr. Jennings had acted properly, and was of opinion that, although in some of her replies to his questions she appeared to be under a delusion, she was perfectly quiet, and he thought she should not be sent to the lunatic department, but kept under supervision in No. 2 Ward. He thought the affairs of the house should be under the control of one medical officer.

It was then resolved to send O'Neill to be kept under supervision.

### MOUNTMELICK UNION.

#### THE ANTICIPATED RESIGNATION OF THE MEDICAL OFFICER.

MR. CULLEN mentioned that he had been canvassed already by several medical officers for the position of medical officer in the house. Now, he thought it would be very wrong for that board to encourage "plurality." It would be right, he thought, to let these candidates know that the board would not sanction or approve of giving two appointments to one man. It was in the interest of the ratepayers that he said so.

Mr. Cobbe proposed the following resolution:—

"That we find several dispensary doctors are seeking the influence and vote of the guardians of the Mountmellick union, we ask the Local Government Board to signify their intention on the subject, viz.: whether the Local Government Board will sanction the wishes of the said guardians of said union in dividing the medical situations of the house and of the Mountmellick dispensary, so as that it will be more in the interest of the poor of a large district of mountain range; so that the said medical officers may not be led into the belief that they may have friends enough to carry both situations, by appointing one officer to the public detriment."

Mr. Sheane did not know how the resolution would bind the dispensary committee.

Mr. Cobbe said it did not bind any one. They were asking for an expression of opinion from the Local Government Board.

The resolution was passed.

#### THE WORKHOUSE AND DISPENSARY MEDICAL APPOINTMENTS.

The following letter was then read:—

"Dublin, 22nd April, 1881.

"SIR,—The Local Government Board for Ireland acknowledge the receipt of minutes of proceedings of the board of guardians of Mountmellick union on the 16th inst., containing a resolution inquiring whether the Local Government Board would sanction a proposal to separate the offices of medical officer of the workhouse and medical officer of the Mountmellick dispensary district, and in reference thereto, the Board desire to state that inasmuch as neither of the offices in question is at present vacant, they are not prepared to offer an opinion on the subject.

"By order of the Board.

"B. BANKS, Sec."

### CAVAN UNION.

#### PAYMENT OF SUBSTITUTES.

The Chairman next read the following letter:—

"SIR,—I enclose a receipt for £23 2s received from the

Cavan Board of Guardians on account, for my services as *locum tenens* to the Arva Dispensary District. I beg leave to say that as I got no intimation from the Board of their intention of only paying me at the rate of £1 1s per week (from the 7th of March until the 4th of April), until my time had nearly expired. I therefore trust the Board will reconsider the matter, and not oblige me to use more stringent measures to recover the balance.

"I remain, truly yours,

"JOHN J. EGAN"

"Coranary Lodge,

"April 18th, 1881.

"DEAR SIR,—At a meeting of the Committee of Management of the Arvagh Dispensary District it was resolved unanimously that it is the opinion of the Committee, that under all circumstances of the case, and considering the satisfaction he afforded while in charge of the Dispensary District as *locum tenens* during the severe illness of Dr. Buchanan, we consider that Dr. Egan should be paid at the rate of £2 2s instead of £1 1s for the last four weeks of his appointment; and we earnestly hope the Board of Guardians will accede to this our request as we were gratified to be able to obtain the services of one who could devote the entire of his time to the duties of the office.

"By order,

"LOUIS GREER, Hon. Sec."

The Clerk said he wrote to the Secretary on the Thursday after the Board decided upon paying him only £1 1s per week.

The Chairman suggested that they should make some rule as to the payment of *locum tenens*; he thought they should give them only 21s. per week and let the Doctor pay the balance; last year they cost the Union close upon £100.

Mr. Duignan approved of the suggestion.

Mr. M'Cann—If we had a fixed rule it would save us a great deal of trouble.

Mr. Faris believed Dr. Egan will certainly process the Board unless they pay his claim.

### SLIGO UNION.

#### PRECAUTIONS AGAINST EPIDEMIC.

THE Committee discussed the out-break of fever in the district.

It appeared that this girl was, with others, a work girl in the employment of a dressmaker, who recently died of fever.

Mr. Walker said it was important that proper steps should be taken to prevent fever being treated in crowded houses or streets.

Mr. Gillmor—This case was seven days in existence before it was reported to the doctor.

Mr. Woods—Everything the Corporation could do, as a sanitary authority, has been done, and the Mayor has got instructions to lay out any sum which may be necessary to prevent contagion.

Dr. Murray said that when there was fever in a house the parties kept it secret.

Mr. Walker—But, when it is found out, have we no power to remove a patient to prevent contagion?

Chairman—We have power to proscribe the place, and prevent any communication with it.

Dr. Laird—I think that when a case is dangerous to health you can remove a patient upon a magistrate's warrant.

Mr. Gillmor—You must have a sworn information first. Mr. Walker was sure the doctors, when necessary, would not refuse to swear such an information.

Dr. Murray said he would, while acting as dispensary doctor, prefer to have such cases removed to the fever hospital.

The members of the committee considered that the doctor had done all he could do under the circumstances.

# IRISH POOR-LAW INTELLIGENCE.

## CORRESPONDENCE.

### LUNACY FEES.

THE following official communication has been recently sent to the Magistrates at Petty Sessions, Drogheda, in reply to their inquiry as to whether the certifying of dangerous lunatics is within the official duty of the dispensary medical officer :—

Dublin Castle,  
March 9th, 1881.

GENTLEMEN,—I am directed by the Lord Lieutenant to inform you, that your letter of the 28th ultimo, relative to payment of fee demanded by medical officer for signing medical certificate, having been submitted to the law adviser, he has given the following opinion thereon :

“The magistrates in this case ought to make an order under 38 and 39 Vic., chap 87, for payment to Dr. Murtagh of a reasonable fee, I do not think he can be legally compelled to give a certificate unless this be done.”

I am, gentlemen,

Your obedient servant,

T. H. BURKE.

### SUCCESSFUL RE-VACCINATION.

THE following letter appeared in the Dublin morning papers of Friday last :—

SIR,—From the report of the judgment delivered by the Court of Queen's Bench in the case of *Duncan v. the Guardians of the Omagh Union*, as reported in your issue of Thursday, it would naturally be supposed that Dr. Duncan had claimed payment for a number of unsuccessful vaccinations, and, upon a point of law had recovered from the guardians fees to which he was not equitably entitled, inasmuch as his operations had failed. As this misconception of the facts would place in a false position before the public both Dr. Duncan and the Irish Medical Association, at whose instance he contested the point, I take leave to explain the sense in which the word “successful” is used in connection with re-vaccination.

A primary vaccination of a child who had not been effectively vaccinated before ought to produce a characteristic vesicle, and a primary vaccination is, therefore, not paid for unless it produces the test of success. A re-vaccination, however, in every case in which the protective influence of the first vaccination continues to exist, produces either no vesicle at all or an abortive one. Therefore a re-vaccination, though it is not and is not expected to be “successful” in the sense of producing a vaccine vesicle is quite effective for the purpose for which it is performed, i.e., to prove that the patient is still under the influence of the original vacci-

nation. It is to prove the security of the patient and to protect anew those whose protection had become weakened that re-vaccination is performed, and it is quite successful when it effects either of these objects. The Act of Parliament, as pointed out by the learned judges, fully recognises, and was constructed to recognise this distinction between success in vaccination and in re-vaccination, and the Local Government Board has carefully pointed out that if a vesicle be not developed, the vaccination is not the less successful in the object for which it is performed. It is needless to observe that if the law were as the Omagh guardians thought it to be, vaccination would cease and small-pox would flourish, because the public vaccinator would certainly not trouble himself to re-vaccinate knowing that in nine cases out of ten no vesicle would appear, and, if this were the test of success, he would in such cases get no fee. The judgment of the court establishes the law that a re-vaccination performed satisfactorily entitles the operator to his fee whether or not it is successful in producing a vesicle.

I am, Sir, yours, &c.,

ARCHIBALD H. JACOB.

23 Ely Place, May 19, 1881.

### DROMORE WEST UNION.

#### DRUG CONTRACT.

THERE were four tenders for medicine, three from Dublin, and one from Messrs Hoffe and Co., Ballina. They were referred to Drs. Mahon and Scott for comparison and report, who reported in favour of Messrs Hoffe.

Dr. Scott—I find in some of the tenders articles seldom or never used put down almost nil, while the articles in chief use are pretty high. These latter articles are charged for more moderately by Mr. Hoffe.

Mr. Boyd said he knew instances where medicines given out were useless.

Messrs. Hoffe's tender was then accepted.

### DRUMQUIN DISPENSARY.

A MEETING of this committee was recently held for the purpose of making a temporary appointment to the vacancy created by the death of Dr. Johnston; Dr. Corry, Carrickmore, received the appointment.

The following resolution expressive of sympathy for Mrs. Johnston was unanimously adopted by the Committee, and copy of same directed to be sent to her—  
“Resolved, that we, the members of the Drumquin Dispensary Committee beg to convey to Mrs. Johnston our heartfelt sympathy in her present sad bereavement in the loss she has sustained by the very sudden and unexpected death of her beloved and affectionate husband. We also

desire to express that by the death of Dr. Johnston the committee have been deprived of the services of an efficient and dutiful medical officer, and the poor of the district in which he resided of a kind hearted and benevolent gentleman."

LIST OF ENTRIES IN THE REGISTER OF THE  
BRANCH MEDICAL COUNCIL (IRELAND) FOR THE  
MONTH OF APRIL, 1881.

APRIL 8th.—Caldwell, Wm. Hamilton; Coleraine, co. Derry; M.D. 1880 and M.Ch. 1880 Q. Univ. Irel.

12th.—Reid, Godfrey Forrest; The Elms, Londonderry; M.B. 1881 and B.Ch. 1881 Univ. Dub., Lic. Mid. K. Q. Coll. Phys. Irel. 1881.

14th.—Martyn, Geoffrey Theodore; Spanish Town, Jamaica; Member R. Coll. Surg. Eng. 1869, Lic. 1870 and Lic. Mid. 1870 K. Q. Coll. Phys. Irel.

14th.—Aird, Thor. Wilson; Templetown, South Shields, co. Durham; Lic. Apoth. Hall, Dub. 1880.

21st.—Wallace, Thomas; Mortalstown, Kilfinane, co. Limerick; Lic. R. Coll. Phys. Edin. 1881, Lic. R. Coll. Surg. Edin. 1881.

21st.—Daly, Patrick Arthur; 83 Leinster Road, co. Dublin; Lic. R. Coll. Surg. Irel. 1880, Lic. 1881 and Lic. Mid. 1881 K. Q. Coll. Phys. Irel.

MEMORANDUM.

The following name was omitted in error from the General Register for 1881, viz.:

June 29th, 1859.—Willis, Thomas; 34 Upper Ormond Quay, Dublin; Member R. Coll. Surg. Eng. 1851, Lic. Apoth. Hall, Dub. 1854, M.D. St. Andrews 1867.

MEMORANDUM.

The following names have been erased from the Register of the Branch Medical Council (Ireland) during the month of April, 1881, pursuant to the 14th Section of the Medical Act, no reply having been received to several letters of application, or as having been reported dead or ceased to practise, viz.:

1872.—Kelly, Peter; Seafield Walls, Shetland. Dead.

1858.—Cryan, Robert; 54 Rutland Square, W., Dublin. Dead.

1876.—Gorman, Patrick; Carrickmacross, co. Monaghan. Dead.

1859.—Taylor, Adrian; Clonlough, Kenmare, co. Kerry. Ceased to practise.

1858.—Twigg, Richard; Clogher, co. Tyrone. Ceased to practise.

1859.—Ryan, John; Ballinacolly, Ennis, co. Clare. Ceased to practise.

1859.—Hamilton, Wm. Richard; Delgany, co. Wicklow. Ceased to practise.

1868.—Sharpe, William; Army Medical Department. Ceased to practise.

1859.—Willis, Thomas; 18 Fortescue Terrace, Rathmines, co. Dublin. Dead.

1867.—MacMullen, Richard; Army Medical Department. Dead.

1872.—Peele, Edward; 41 Lower Baggot Street, Dublin. Dead.

1880.—Moloney, Denis; Brozna, co. Kerry. Dead.

1864.—Horan, Patrick Callan; Whitehaven. Dead.

1859.—Long, Oliver Joseph; Portarlinton, Queen's co. Dead.

1859.—Tydd, Benjamin; Army Medical Department. Dead.

1858.—McManus, James Henry; New Street, Longford. Dead.

1880.—Foley, Michael Doyle; Killorglin; co. Kerry. Dead.

1858.—Stokes, Gabriel; Mullingar, co. Westmeath. Dead.

1872.—Stanistreet, Thomas Dawson; Cowbridge, Glamorganshire. Dead.

1866.—Longheed, William; Army Medical Department. Dead.

MEMORANDUM.

The following names have been restored to the Register per order of Council, viz.:

July 24th, 1864.—McCarthy, John Winspeare; 1 Clarendon Terrace, Leytonstone Road, Stratford; M.D. Q. Univ. Irel. 1864, Lic. R. Coll. Surg. Edin. 1864.

Dec. 24th, 1877.—Dedrickson, Robert Forrest; 4 Chouinghee, Calcutta; Lic. R. Coll. Phys. Edin. 1877, Lic. R. Coll. Surg. Edin. 1877.

August 3rd, 1874.—Forster, John Burke; Rinroe, Corofin, co. Clare; Lic. R. Coll. Surg. Irel. 1873.

IRISH MEDICAL ASSOCIATION.

REPORT OF THE COMMITTEE OF COUNCIL,  
For the Quarter ended 25th March, 1881.

(Read and adopted at the Meeting of Council held 25th March, 1881.)

DR. J. W. MOORE, President of Council, in the chair.

MR. CHAIRMAN AND GENTLEMEN,—During the past quarter one Special General Meeting of the Association and one Special Meeting of the Council have been held; the Committee of Council have held sixteen meetings, and eight new names were added to the list of members.

SUPERANNUATION OF MEDICAL OFFICERS.

A special general meeting of the Association was held on 15th January last, to consider the subject of superannuation of medical officers of the Poor-law service, when the following resolutions were adopted:—

1. "That a superannuation allowance of the full pay and emoluments should be claimable as a matter of right, upon retirement, by all medical officers of the Poor-law service who have served forty years."

2. "That a superannuation allowance of two-thirds of the salary and emoluments should be claimable as a matter of right, upon retirement, by all medical officers of the Poor-law service who have served thirty years, or who have become incapable of performing their duties with efficiency by reason of old age (such age being not less than sixty years), or permanent infirmity of mind or body."

3. "That any medical officer in the Poor-law service not qualified, as aforesaid, to claim the maximal pension, shall be entitled upon retirement, at any time after a period of ten years' service, to a retiring allowance of one-fortieth of his salaries and emoluments at the time of his retirement for every year served."

4. "That the period of service of a medical officer in the Poor-law service shall comprise all the years he held office as such, whether in one or more unions, and that his superannuation allowance shall be computed thereon; the Local Government Board having power (in the event of such officer having served in more than one union) to decide whether his pension shall be payable wholly by the union in which said officer last served, or partly by each said union, proportionately or otherwise, as the said board shall deem expedient."

5. "That the Committee of Council do take immediate steps to have a Bill embodying these resolutions, drafted by counsel and submitted to Parliament; and that the Committee of Council are hereby authorised to accept on behalf of this Association the best terms obtainable, after due exertion, for a system of compulsory superannuation on the lines above laid down, or as near thereto as may be."

A deputation from the Committee of Council waited upon Mr. Meldon, M.P., within the past few days, to consult with him on the subject of compulsory superannuation of Poor-law medical officers, when he suggested the advisability of an interview with the Chief Secretary, and the Committee of Council are now seeking for the receipt of a deputation to the Chief Secretary, to discuss with

him the merits of a Bill to provide for compulsory super-annuation of Poor-law medical officers, based upon the terms of the above resolutions.

The Committee of Council consider that a measure containing such provisions would, if enacted, prove thoroughly satisfactory to the medical officers of the Poor-law service, and although every effort shall be made to obtain such desirable terms the Committee of Council, nevertheless, consider that as the proposal of the first resolution is unprecedented as a legislative enactment, it can hardly be considered obtainable.

**MEDICAL REFORM.**

In the last report of the Committee of Council it was stated that they had been successful in bringing about a conference of the various organisations representative of professional opinion, and that that conference had arrived, with unanimity, at a series of resolutions, upon which it was intended to frame a Bill for introduction to Parliament, to express the opinions of medical practitioners throughout the kingdom. That Bill, of which a copy lies on the table for your inspection, has since been introduced by Mr. Hardcastle, Dr. Farquharson, and Sir Trevor Lawrence, and stands for a second reading on the 29th of June. Its provisions are in complete conformity with the policy adopted by this Association, the principles of which have been confirmed and accepted by the leading representative organisations in England with an unanimity which cannot fail to be gratifying to the Council. Shortly after the introduction of the Bill, the Vice-President of the Privy Council, Mr. Mundella, was interrogated by Mr. Errington, M.P., as to the intentions of the Government upon the Medical Reform question, when he stated that it was not their intention to deal with the matter, but they would consider the propriety of submitting it to a Royal Commission, which course has been since decided upon. The Commission has not yet been appointed, nevertheless the effect of this determination will be to postpone until next session all projects of medical reform, and to re-open the inquiry which had been partially held before the Select Committee of the House of Commons last year. The Committee of Council—while approving of the fullest inquiry into the state of our profession, the medico-educational system, and the execution of their functions by the General Medical Council, and feels confident that minute examination of the question will confirm the policy adopted by the Association—nevertheless, are of opinion that the facts which justify a thorough reform of the system are already so fully recognised and understood that a further inquiry by a Royal Commission will produce no beneficial result, while it will cause a regrettable delay in the settlement of the medical reform question. When the Commission is appointed, the Committee of Council will apply for leave to be heard in evidence before it; and in case that application be granted, the influence of the Association will be exerted to advance its policy.

**NOTIFICATION OF INFECTIOUS DISEASES (IRELAND) BILL.**

A Bill to provide for registration of infectious diseases in Ireland has been brought in by Messrs. Gray, Brooks, and Barry, which empowers the Local Government Board, upon the application of any sanitary authority, to declare its provisions in operation within the district of such authority.

That Bill proposes that the duty of giving notice to the sanitary authority shall be compulsorily imposed on the medical attendant, who, for his certificate, is to be paid a fee of one shilling, but nothing for any case of the same disease occurring in the same house within thirty days of the date of the first certificate.

The Committee of Council deemed it advisable to take a plebiscite of the medical practitioners residing in the Dublin sanitary district on this question, and accordingly issued a circular containing certain queries as to the mode of notification, if any, preferred, the result of which was:—

1. Do you approve of the medical attendant being,

directly or indirectly, the informant, in writing, of the sanitary authority?

Affirmatives ... .. 60  
Negatives ... .. 104

2. If you approve, which proposition (a or b) do you prefer?

(a) Either that the medical attendant shall, on recognising an infectious disease, fill up, sign, and hand to the custodian of the patient, or to the occupier of the house, a printed notice containing the name and address of the patient, and a statement as to the nature of the disease, which notice the recipient shall be bound to bring or send forthwith to the clerk of the sanitary authority;

(b) Or that the medical attendant shall, himself, transmit such notice to the clerk of the sanitary authority, immediately after he has left the patient.

Affirmatives { "a" 31 }  
Negatives { "b" 29 } Negative, 49

3. If you do not approve of a or b, do you approve of c?

(c) Or that the custodian of the patient, or house occupier, solely, shall be made directly responsible to ascertain, from a registered medical practitioner, the nature of the sickness, and to report same to the sanitary authority, subject to penalties for omission to do so.

Affirmatives ... .. 109  
Negatives ... .. 23

371 circulars were issued, and 201 replies received; three of the gentlemen to whom the circular was issued were absent, and 167 did not reply.

The Bill was brought under the notice of a special meeting of the Council, held 25th January last, when it was discussed, and the following series of resolutions adopted, viz:—

I.—“That this Association, while re-affirming the resolutions of the Council adopted on the 27th July, 1880, as to the advantages of early notification of infectious disease, is of opinion, that the proposal to compel the physician to make a formal written notification, either to the sanitary authority or to the custodian of the patient, would, if carried into effect, be of doubtful advantage to the public, and be oppressive upon the medical profession.”

II.—“That this Association does not admit the principle that a physician should be required to apply to public uses the information obtained by him in his capacity of a private practitioner; and the Association, furthermore, apprehends that if it be declared that the visit of a physician to a patient suffering from an infective disease shall be, of necessity, followed by the putting in motion of the sanitary law with regard to the infected house, a great inducement will, thereby, be afforded to defer calling in a physician until the disease has acquired such intensity that it can no longer be concealed, and must therefore be treated under great disadvantages.”

III. That the Association cannot assent to the sacrifice of professional principles and medical interests which the Bill, now before Parliament, involves until the custodian of the patient has been made fully responsible, under penalties, both to ascertain from a medical practitioner the nature of the disease, and to report the same to the sanitary authority; and until, after an effort made to enforce such responsibility, with vigilance and firmness, it has been found to be impracticable to do so.”

IV. That, irrespective of the objectionable principles of the Bill already referred to, the proposals—to pay to the physician one shilling for thirty days' notification of cases occurring in an infected house, to pay no fee whatever for such services in a public institution, to compel the physician to attend in court without fee to prove his certificate if necessary, and to impose a penalty of £5 upon him for such omission to notify—are altogether unacceptable to the profession.”

V. That, therefore, the Committee of this Association be instructed to take all necessary steps to cause the Bill to be modified in its passage through Parliament, or to oppose its passing if necessary.”

A petition to have the Bill modified has been sent to the House of Commons, and Dr. Lyons, M.P., has been

requested to endeavour to have the views of this Association carried out with regard to it.

The following is the petition which was forwarded :—

*To the Honourable the Knights, Burgesses, and Commons,  
in Parliament assembled.*

The Petition of the President of the Council of the Irish Medical Association humbly sheweth that your petitioners are the executive of an Association devoted to representing the opinions and interests of the medical profession in Ireland, and including amongst its members a large proportion of the legally qualified medical men in practice in Ireland. That your petitioners have fully considered the Notification of Infectious Diseases (Ireland) Bill, now standing for a second reading in your honourable House, and have obtained the opinion of a large majority of the medical practitioners of the city of Dublin upon the chief proposals contained in said Bill, which opinion has been expressed by a majority of nearly two to one against any proposal which would require the medical attendant to notify, in writing, the occurrence of infectious disease, either to the sanitary authority or to the house occupier.

Your petitioners confirm the opinion thus expressed, and consider that the provisions of said Bill are not calculated to effect, with certainty, the discovery of infective disease in those instances in which concealment is most probable, while they will, if passed into law, impose upon the medical profession new functions inconsistent with the efficient performance of their duty towards their patients, and seriously prejudicial to their interests as practitioners.

That your petitioners apprehend that if, as would occur under the operation of said Bill, the visit of the physician be followed by the immediate enforcement of sanitary precautions, a great inducement will be created, in all instances in which it is desired by the house occupier to avoid the application of the sanitary law, to omit sending for a medical attendant, or to defer doing so until the disease had reached a stage in which its treatment would be difficult and ineffective. Your petitioners, therefore, anticipate that the number of undetected cases of infective disease might rather increase than diminish under the operation of the proposed law, while, in many instances, the chances of restoration of the patient to health would be greatly prejudiced.

Your petitioners humbly submit that the professional and monetary relations existing in Ireland between the physician and his patient are altogether different from those which exist in other divisions of the kingdom, and furthermore that the methods of application of sanitary laws in Ireland are not fairly comparable with those which exist elsewhere, and your petitioners, therefore, submit that a system of notification of infective disease, applicable to England and Scotland, may prove altogether unsuitable to Ireland, and they are of opinion that any enactment which requires the medical attendant in Ireland to give a written certificate of the disease from which his patient is suffering, will be inoperative in many instances, and will tend to increase the evil which it purports to remedy.

Your petitioners are furthermore strongly of opinion that, in respect of the fee proposed to be paid for such notification, the penalty imposed for omission to notify, and in other details, the said Bill is altogether objectionable.

Your petitioners, therefore, humbly pray that your honourable House will not pass said Bill.

(Signed)

JOHN H. CHAPMAN, President.

ROBERT BROWNE, Hon. Sec. of Council.

#### PETITIONS TO PARLIAMENT.

The following petitions to the House of Commons have also been recently forwarded, viz. :—

A petition in favour of medical reform.

A petition praying for extension to Ireland of the English system of awards for excellence in vaccination.

A petition praying that the medical officers of health may either be equitably remunerated for their services, or be relieved from compulsory acceptance of the position.

#### CORONERS' BILL.

A new Bill to amend the Coroners' Acts of Ireland is now before Parliament, and has been referred to a Select Committee.

The measure, so far as it goes, is not unsatisfactory, and if there be a reasonable prospect of its advancing further, the Committee of Council will seek to have inserted in its clauses, to provide more satisfactorily than the existing law does, for the selection of medical witnesses, and for payment of fees to physicians and surgeons attached to hospitals and other public institutions.

The Committee of Council are informed that a coroner who, on a former occasion, refused to pay a prison surgeon for his evidence as to the cause of death of an executed convict, again denies the legality of a similar claim made by the same surgeon, although, in the first instance, the question was argued before the Grand Jury who presented for the surgeon's fees which were paid (see report for quarter ended 21st April, 1879, p. 31 to 34).

The Committee of Council have just learned, with satisfaction, that the Grand Jury, having been informed of the facts of the new case, at once agreed to present for payment of the fee.

#### DISPENSARY MEDICAL OFFICERS.

The Board of Guardians of Granard Union having advertised that a medical officer would be appointed to a dispensary district within that union, and that no additional fees would be paid for attendance at Petty Sessions to give evidence in sanitary or vaccination prosecutions, the Committee of Council directed the attention of the Local Government Board to the terms of the advertisement, and requested that an appointment made under such conditions, with regard to fees in cases of vaccination prosecutions, should not be sanctioned, and in reply, the Local Government Board stated that the medical officer will be entitled to the prescribed fees.

The guardians, however, have power to impose the above condition as regards attendance in sanitary prosecutions, provided it be agreed to by the medical officer of health.

#### ASSESSMENT OF SUPERANNUATION ALLOWANCES.

A letter has been addressed to the Right Honourable the Chief Secretary for Ireland, asking whether the opinion of the law officers had been taken with regard to the question of assessment of superannuation allowances of dispensary medical officers, which had been brought under his notice by the deputation which waited upon him on the 1st November last (see last report, pp. 11-15), but no reply has yet been received.

#### MEDICAL OFFICERS OF HEALTH.

The Committee of Council not having received any reply to the memorial forwarded to the Treasury, on 22nd November last (see last report, pp. 15-20), again communicated with that department, and were informed that the memorial had been sent for consideration to the Irish Government, who had not replied.

The Committee of Council thereupon addressed a letter to His Excellency the Lord Lieutenant, inquiring if any decision had been arrived at relative to the prayer of the memorial, but, as yet, have received no reply.

(To be continued.)

# IRISH POOR-LAW INTELLIGENCE.

## IRISH MEDICAL ASSOCIATION.

ANNUAL GENERAL MEETING,  
6th June, 1881.

*Report of Council for the Year ending 31st May, 1881.*

Mr. PRESIDENT AND GENTLEMEN,

During the past year your Council held seven meetings, and the Committee of Council fifty-three meetings.

As customary in the annual reports, your Council give precedence to matters relating to legislation, referring first to those already disposed of, and subsequently to those still under the consideration of Parliament.

### REGISTRATION OF BIRTHS AND DEATHS.

Since the last annual report was submitted, "The Registration of Births and Deaths Amendment (Ireland) Act" has become law. The Bill as originally introduced was drawn up by your Council some years ago with the object of removing many harassing and unnecessary requirements, which, while causing great and useless trouble to the public as well as to the registrars, at the same time seriously interfered with the objects of the law. Your Council, while regretting that some important clauses in the Bill were struck out, regard the new Act—which affords a much more perfect system of registration—as a decided improvement in the law, which is now more nearly assimilated to that in force in England, compared with which it is, however, in some respects more satisfactory.

A special report on the new Act and the changes made by it appeared as an appendix to the Report of the Committee of Council for the half-year ended last December.

The new Act came into operation on the 1st January of this year, and although the changes necessarily involved for a time considerable extra work to the registrars, your Council believe that the Act will be more satisfactory to the public, while it will diminish the labours of the registrars without reducing their emoluments. Your Council gratefully acknowledge the valuable services rendered to this Association and the public by the Right Hon. the Viscount Powerscourt and Mr. Meldon, M.P., who undertook charge of the Bill in the Houses of Parliament to which they respectively belong, and the thanks of your Council have been duly conveyed to them.

### THE MEDICAL CHARITIES AMENDMENT BILL.

The Bill to amend the law relating to Medical Charities in Ireland, to which reference was made in the last annual report as having been introduced, was

not favourably received in the House of Commons; your Council therefore deemed it better to have the Bill withdrawn until the legislature was more fully informed as to the nature and extent of the abuses to which the present system of Poor-law medical relief is subject. It is to be hoped that a measure will then be enacted which shall, as equitably as possible, define clearly who are to be eligible to receive dispensary medical relief, the term "poor person," now adopted, being too vague for the purpose: and that thus a stop shall be put to "well-to-do," or comparatively wealthy, ratepayers obtaining medicines and medical attendance gratuitously at the expense of others who have higher ideas of self-respect and honour. The imposture thus referred to presses very heavily especially on the medical officers, who, in consequence, are compelled to give valuable time and services gratuitously to persons who can well afford to pay for them; it also causes a serious misappropriation of the poor-rates. But the unworthy recipients of such relief are not the only persons to blame; quite as much so are the persons authorised to issue tickets, who carelessly, and often for gain, abuse the privileges conferred upon them. Your Council trust that an amendment of the law may soon be made which shall attach reasonable liabilities to persons who either improperly issue such tickets, or who, through wilful misrepresentation, obtain them, and they further trust that better regulations may soon be enacted to secure that pure drugs shall be provided for the treatment of the sick poor of the dispensary districts of Ireland.

### AMENDMENT OF VACCINATION ACT.

Late in the last Session of Parliament a Bill was introduced in the House of Commons by Mr. Dodson, M.P., to abolish cumulative penalties for default of vaccination, and your Council, being convinced that the Bill, if passed, would have a disastrous effect upon the public health, though probably not affect medical interests appreciably, forwarded to Parliament a strong petition against the proposed alteration of the law, whereby vaccination would practically cease to be compulsory.

Your Council gladly report that the Bill was withdrawn, and they trust that no further attempt may be made to introduce such a measure.

### MEDICAL REFORM BILLS.

The subject of medical reform received the attention of your Council, who considered it very desirable that an effort should be made to arrive at a general agreement amongst medical reformers upon a single bill which would fully represent the views of the profession before the opening of the present session of Parliament. It was, therefore, proposed by your Council that a conference of those who took an active part in putting forward legislative measures should be held in London.

With this object, and the suggestion having been accepted with much cordiality by the representatives of the Medical Reform Committee of the British Medical Association, the Medical Alliance Association, by the proprietors of the *Lancet*, and by other influential members of the profession, a conference was held in London, at which this Association was represented by Dr. A. H. Jacob.

At that conference the various bills which were before Parliament last session were considered, and a series of resolutions adopted as the basis of a bill to be introduced as early as possible after the assembly of Parliament.

The Bill then agreed upon has since been introduced by Mr. Hardcastle, Dr. Farquharson, and Sir Trevor Lawrence, and stands for a second reading on the 29th of June. Its provisions are in complete conformity with the policy adopted by this Association, the principles of which have been confirmed and accepted by the leading representative organisations in England with an unanimity which cannot fail to be gratifying to this Association. Shortly after the introduction of the Bill, the Vice-President of the Privy Council, Mr. Mundella, was interrogated by Mr. Errington, M.P., as to the intentions of the Government upon the Medical Reform question, when he stated that it was not their intention to deal with the matter, but they would consider the propriety of submitting it to a Royal Commission, which course has been since decided upon. The Commission has recently been appointed; nevertheless, the effect of that course of procedure will be to postpone until next session all projects of Medical Reform, and to re-open the inquiry which had been partially held before the Select Committee of the House of Commons last year. Your Council—while approving of the fullest inquiry into the state of the profession, the medico-educational system, and the execution of their functions by the General Medical Council, and feeling confident that minute examination of the question will confirm the policy adopted by this Association—nevertheless, are of opinion that the facts which justify a thorough reform of the system are already so fully recognised and understood that a further inquiry by a Royal Commission will produce no beneficial result, while it will cause a regrettable delay in the settlement of the Medical Reform question. Your Council have applied for leave to be heard in evidence before the Commission; and expect that they will be soon called upon to send their delegate to give evidence, when Dr. J. W. Moore, the outgoing Chairman of Council, who has long since carefully prepared his evidence on behalf of this Association, will be requested to present himself before the Royal Commission for the purpose of submitting it.

The following are the reforms to which this Association has already pledged itself, viz. :—

1. A revision of the constitution of the General Medical Council—
  - (a) By a more equitable distribution of seats amongst the licensing authorities.
  - (b) By widening the constituencies which elect the representatives of several of those bodies.
  - (c) By a more direct representation of the general body of the profession.
2. The grant to the Medical Council of complete control over the education and examination of candidates for admission to the profession.
3. The compulsory establishment of a single conjoint examination for each division of the United Kingdom, which examination should be essential for admission to the licence or degrees of any of the medical authorities.
4. The enforcement of absolute uniformity in standard of examination, extent of curriculum, and amount of fees payable, required by each and all of the conjoint examining bodies.

#### SUPERANNUATION.

During the past year unceasing attention has been bestowed by your Council on the very important subject of superannuation, and they have pleasure in reporting that their exertions appear to have had much good effect.

At the instance of your Council a very grave example of recent injustice was brought under the notice of Parliament by Mr. Meldon, M.P., who, on the 10th August last, gave notice of the following question in the House of Commons, viz. :—

“To ask the Chief Secretary to the Lord Lieutenant of Ireland if it is the case that the Medical Officer of the Crossgar Dispensary District, in the Union of Banbridge, having, after forty years' service, applied for superannuation on the ground of broken-down health, the Guardians, at a meeting, passed a resolution ‘to record on the minutes their approval of the manner in which the Medical Officer has filled such office for a period of forty years, but that the Guardians cannot add to the rates by granting any retiring allowance.’ Whether the passing of such a resolution, under the circumstances, fairly carries out the principle of the Medical Officers' Superannuation Act. If the Local Government Board can or will interfere in the matter; and if the Government will promote or support a measure to make the superannuation of the Poor-law medical officers in proper cases compulsory on boards of guardians.”

To this question the following reply was made by the Right. Hon. W. E. Forster, Chief Secretary for Ireland, viz. :—

“Sir, the facts, as stated by the hon. and learned gentleman, are true. It is, no doubt, a case of great hardship; but the Guardians did not think fit to make the allowance, and the Local Government Board have no power to interfere in the matter. I think I have stated before, in reference to an inquiry as to the superannuation of those officers, that the subject was one which occupied largely the attention of the Government, and I hope we may be able to deal with it next year.”

On the same day Mr. Meldon, M.P., obtained an order of the House of Commons for a return to be made giving the names of all medical officers of workhouses and dispensaries in Ireland who, since the passing of the Medical Officers' Superannuation Act, 32 and 33 Vic., c. 50, have resigned their offices, and applied to their boards of guardians for superannuation allowances under that Act, with the causes for such resignation, the ages, and length of service of Poor-law medical officers, of each person at date of resignation; the result of such application to the guardians, and the reason, if any, given by the said guardians for refusing the application.

The return showed several cases of great hardship owing to refusal of some boards of guardians to recognise, by the award of a well-merited pension, long and faithful services. But it referred only to cases in which application for retiring allowances had been made, and of course did not afford information as to the very numerous instances in which medical officers after long service, knowing it to be utterly useless to ask for a retiring allowance, never even made an application for it. Many such medical officers were not only incapable of further work, owing to advanced age or bodily infirmity, but in greatly straitened circumstances, if not absolute penury.

The proceedings of that most estimable institution, the Royal Medical Benevolent Fund Society of Ireland—a Society truly worthy of the warm support of the profession and the public—abundantly prove the inability of the medical officers to make sufficient provision for themselves and their families, and their poverty when they have been rendered unable to discharge their duties any longer.

A deputation from a large and influential meeting of the Irish union officers, held in Dublin, waited on the Committee of Council to confer with them as to the

possibility of agreeing to a general scheme of superannuation for all union officers, including all medical officers in the Poor-law service; and subsequently several other conferences were held between representatives of the union officers and of the Committee of Council, which resulted in the drafting of a Bill for further consideration.

On the 15th January a special general meeting of the Association was held to consider what amendment of the Superannuation Acts would meet the requirements of the Poor law medical officers and be at the same time consistent with the public interest. At that meeting a series of resolutions, which were published in the report for the quarter ending 25th March last, were adopted to form the basis of a new Bill. Your Council without delay formulated the recommendations of the meeting, and on Easter Monday a deputation from the Council had the honour of an interview with the Right Hon. W. E. Forster, Chief Secretary for Ireland, to whom they were submitted.

The Chief Secretary, having heard the views of the deputation, admitted that a strong case had been made out for amendment of the present law; and acting upon his suggestion, your Council drew up a Bill for presentation to Parliament, which has since been handed to Mr. Meldon and other members to introduce.

The proposed Bill simply seeks that the provisions of the Superannuation Act of 1859 (better known as the Civil Servants' Superannuation Act) shall be extended in a slightly modified manner, without, however, any infringement of its principles, to the medical officers of the Poor-law Service, to whom your Council are convinced it will prove satisfactory; and they are glad to be able to report that they understand the proposed Bill has been already favourably considered by the Government and the Local Government Board for Ireland.

The following are the terms of the proposed Bill, to which references showing the existing precedents for each clause have been added for convenience and explanation.

POOR LAW MEDICAL OFFICERS' SUPERANNUATION  
(IRELAND) BILL.

Whereas it is expedient to alter the law providing superannuation allowances for medical officers of unions and dispensaries in Ireland.

Be it, therefore, enacted by the Queen's Most Excellent Majesty, by and with the advice and consent of the Lords, Spiritual and Temporal, and Commons in Parliament assembled, and with the authority of the same, as follows:—

I. Repeal—

32 and 33 Vic., chap. 50, the whole Act;  
35 and 36 Vic., chap. 89, part of sec. 2, viz. :—the words "Registrars of Births and Deaths," and "Registrars of Marriages."

but such repeal shall not affect any superannuation allowance granted, or act done, before the passing of this Act.

cf. "The Superannuation Act, 1859," 22 Vic., cap. 26, sec. 2.

II. The board of guardians of any union in Ireland shall, with the consent of the Local Government Board for Ireland, grant to any medical officer of said union, or any medical officer of a dispensary district in said union, an annual allowance, upon his retirement from said office, at the following rates, that is to say—

To any medical officer who shall have served ten years and upwards, and less than eleven years, an annual allowance of ten-sixtieths of the annual salary and emoluments of his office.

For eleven years, and less than twelve years, an annual allowance of eleven-sixtieths of such salary and emoluments:

And in like manner a further addition to the allowance of one sixtieth in respect of each additional year of such service, until the completion of a

period of service of forty years, when the annual allowance of forty-sixtieths may be granted, and no addition shall be made in respect of any service beyond forty years.

cf. Medical Officers' Superannuation (Ireland) Act, 32 and 33 Vic., cap. 50, sec. 1.

III. The board of guardians of any union in Ireland shall, with the consent of the Local Government Board for Ireland, grant to any medical officer of said union, or any medical officer of a dispensary district in said union, who, after ten years' service, shall have become incapable of discharging the duties of his office with efficiency, by reason of permanent infirmity of mind or body, or of old age (such age being not less than sixty years), upon his resigning, or otherwise ceasing to hold his office, an annual allowance of two thirds of his salary and emoluments at the time of his retirement.

cf. The Superannuation Act, 1859, 22 Vic., cap. 26, sec. 4.

IV. A number of years, not less than ten or exceeding twenty, according as the Local Government Board shall see fit and direct, shall be added to the number of years during which any medical officer shall have actually served in the Poor-law service, and the amount of superannuation or retiring allowance to be granted to such medical officer shall be computed thereon.

cf. "The Superannuation Act, 1859," 22 Vic., cap. 26, sections 5 and 6.

V. It shall be lawful for the Local Government Board, upon any medical officer being compelled by reason of severe bodily injury occasioned (without his own default) in the discharge of his public duty, or constrained from infirmity of mind or body, to vacate his office before the completion of the period of service which would entitle him to a superannuation allowance, to direct that the guardians of the union in which said officer served shall pay him such sum of money, by way of gratuity, as the said Local Government Board may think proper, but no such gratuity shall exceed the amount of one month's pay and emoluments for each year of service.

cf. Union Officers' Superannuation (Ireland) Act, 28 Vic., cap. 26, sec. 2.

VI. All allowances payable under the provisions of this Act shall be payable to, or in trust for such medical officer only, and shall not be assignable or chargeable with his debts or other liabilities.

VII. The term salary and emolument shall include all salaries, fees, allowances, and emoluments receivable by said medical officer in virtue of his office, and from every office connected therewith by statute.

NOTIFICATION OF INFECTIOUS DISEASES.

The attention of your Council has been seriously engaged concerning the subject of notification of infectious diseases.

On the 27th July of last year a special meeting of the Council was held to consider the question, and a series of resolutions were then adopted which were published in the report for the half year ended 7th December last, recognising the advantage of an efficient system of early and compulsory notification of infectious diseases, while emphatically protesting against the onus of such notification being compulsorily imposed upon medical practitioners, and suggesting that such duty should attach to the householders, for whose benefit the advantages of the proposition were intended.

The subject was soon brought under the notice of the Right Hon. the late Lord Mayor of Dublin, Mr. Edmund Dwyer Gray, M.P., Chairman of the Public Health Committee of the Corporation of Dublin, by whom, and Messrs. Brooks and Barry, a Bill was introduced in Parliament this Session to provide for notification of infectious diseases in Ireland, and to empower the Local Government Board, upon the application of any sanitary authority to declare its

provisions in operation within the district of such authority.

The Bill proposed that the duty of giving notice to the sanitary authority as to every case of infectious disease should be compulsorily imposed, under penalty of five pounds, on the medical attendant, who for his certificate was to be paid one shilling, but nothing for any further case of the same disease occurring in the same house within thirty days of the date of the first certificate.

Your Council, feeling that such a measure would not be approved by the profession, took a plebiscite of the views of the medical profession of Dublin with regard to the whole question; the result of which was disapproval, by a large majority, of the terms of the Bill.

A further special meeting of the Council was held on 25th January last, when the resolutions adopted on the 27th July were re-affirmed, and directions were given to the Committee of Council to endeavour to have the Bill modified, or rejected if necessary. A deputation from the Council waited on Dr. Lyons, M.P., who undertook to represent in the House of Commons the views of your Council with regard to the measure. Your Council also addressed a letter to Mr. Gray, M.P., conveying to him a copy of their resolutions, and requesting him to have the terms of his Bill amended accordingly; and a petition, similar in effect, was forwarded to the House of Commons.

Your Council greatly regret that a measure so desirable in object should, owing to the very objectionable terms of its details, have required to be met with opposition on the part of this Association. In the interest of the public they, however, trust that a Bill to provide for early notification of infectious disease in Ireland may soon be passed which will not be objectionable to the members of the medical profession.

Your Council conceive that such a measure, with the duty of giving notice imposed upon the householders, in whose interest it is proposed, would not be objected to by the members of the medical profession, even though it must of necessity be antagonistic to their own, as they invariably evince a spirit of philanthropy in such matters, but it cannot be expected that they will quietly submit to so ruthless an infringement of their interests as Mr. Gray's Bill proposes.

#### THE LUNACY LAW ASSIMILATION (IRELAND) BILL.

A bill under this title, introduced in the House of Commons by Mr. Litton, Mr. Findlater, and Sir Thomas McClure, now awaits second reading. The measure is almost identical with that introduced last year in the House of Peers by Lord O'Hagan, which was referred to in a former Report. Its purpose is:—

1. To provide for the boarding out of harmless lunatics, so as to relieve the asylums, and thus make room in those institutions for curable cases.

2. To enable lunatics in the incipient state to be sent to asylums before the malady has become confirmed, and before the lunatic has become so intent on committing a crime as to be brought under the operations of the Dangerous Lunatics' Acts.

3. To provide for periodical supervision of those "boarded-out" lunatics by the dispensary medical officers of the district, in order that their proper and orderly maintenance may be ensured.

4. To give power to the guardians to vote outdoor relief to a family when one of its members is a lunatic or idiot, the existing power being restricted to the head of the household.

Under the terms of the Bill, every pauper lunatic not in an asylum is to be visited once in every quarter by the medical officer of the dispensary district, who is to be paid 2s. 6d. for each visit to any pauper lunatic not being in a workhouse; and after the end of every quarter the medical officer is to prepare a list of all such lunatics, and state therein whether they properly remain out of an asylum.

Every medical officer, relieving officer, or constable, who comes to know of the existence of an uncared-for lunatic, whether pauper or not, is to notify the matter to the nearest magistrate, who is to have the lunatic brought before him and medically examined, and is thereupon to send the patient, if certified to be insane, to an asylum, or under proper care and custody.

Your Council consider the Bill deserving of support, if amended in certain details. The proposal of the Bill that medical fees shall be paid in the same way as fees for examination of dangerous lunatics are now paid (*i.e.*, at the discretion of the magistrate) your Council consider objectionable, as they hold that the examining physician is entitled to payment as a matter of right. They have also availed themselves of the opportunity to seek for an assimilation of the Irish law in reference to superannuation of medical officers of asylums to that in force in England. The English officer may, at present, receive a pension of two-thirds of his salary and emoluments after fifteen years service in one or more asylums, whereas the Irish officer must serve forty years in *one asylum* before he can obtain the same allowance—an arrangement which has caused much discontentment and produced stagnation in promotion. These two points your Council have embodied in a petition which they have prepared for presentation to Parliament, and which now lies on the table for signatures.

#### CORONERS' (IRELAND) BILL.

A Bill to amend the Coroners' (Ireland) Act is now under the consideration of Parliament, and your Council, having given careful attention to its clauses, see nothing in them to which they can reasonably object. They, however, have taken advantage of the opportunity thus afforded, and are seeking to have some new clauses added to the Bill to provide more satisfactorily for the qualification and remuneration of medical witnesses at coroners' inquests.

Under the law at present in force, a coroner is required, when medical testimony is necessary, to call to his assistance a duly qualified medical practitioner who is at the time in actual practice at or near the place where the death occurred, and although, very properly, the coroners have usually called in the medical practitioner, if any, who was in recent attendance upon the deceased, some coroners, when holding inquests on bodies of persons not recently under medical care (and these form the great majority of subjects for inquests), evade the spirit of the law and call in only their relatives or special favourites who certainly are not in actual practice at the place or at all near to it, the vagueness of meaning of the word "near" admitting of such practices.

In country districts, especially, your Council consider that the dispensary medical officers, who are charged with gratuitous attendance on police cases, have the best claim to be called in to give evidence as to the cause of death of persons who were not under medical treatment; in cities and large towns, where there is greater scope for selection of medical witnesses, your Council see no reason to so limit the coroner's discretion, provided he strictly observes the spirit of the law.

There is another point, which, in justice, requires to be amended, *viz.*: the liability of hospital physicians and surgeons to be summoned by the coroner to give evidence. It is most unreasonable that medical practitioners holding honorary appointments should, in consequence, be compelled, at great loss of valuable time, to give gratuitous services to the State, and it is not in harmony with the public interest that such a system should be continued, inasmuch as it has led to the testimony of unqualified students in such cases being almost invariably given.

Your Council have forwarded observations to the above effect to the Select Committee appointed by the House of Commons to report on the Bill.

# IRISH POOR-LAW INTELLIGENCE.

## IRISH MEDICAL ASSOCIATION.

The Annual General Meeting of the Association was held on Monday, the 6th inst., at the Royal College of Surgeons in Ireland, and was attended by a very large assembly of both metropolitan and provincial practitioners. The chair was taken at 12 o'clock, p.m., by Dr. J. H. CHAPMAN, President of the Association.

The minutes having been read and signed, the Assistant-Secretary read the Report of Council, which appeared in *extenso* in our last issue. Its adoption was moved by Dr. Nugent Duncan, and seconded by Dr. Jacob.

Dr. ROBERT MACDONNELL moved, as an amendment, the omission of the paragraphs of the report which expressed the policy of the Council of the Association as in opposition to the Notification of Infectious Diseases Bill. He referred to the fact that all parties agreed in opinion that notification of infectious disease by someone was desirable, and considered that the policy of opposition adopted by the Council was wrong, inasmuch as he thought it might be amended, and made a satisfactory measure if allowed to go before a select committee. It was, nevertheless, his opinion that the householder was the proper person to notify, and to suffer the penalty if he omitted to do so; and he did not think it reasonable to impose fines and prosecutions upon the medical attendant, who was not legally or personally responsible for the case.

Dr. J. W. MOORE seconded the amendment. This subject had been considered both by the Committee of Council and by the Council generally, and there was no second opinion as to the utility of some system of notification. The only question was how was it to be done. In his opinion the only satisfactory course would be for the physician, as soon as he recognised a case of infectious disease, to at once communicate the facts relating to it to the sanitary authority, and it should be done in writing. Otherwise there would be no such thing as notification. Mr. Gray had already in an enlightened spirit accepted an amendment of his bill, to the effect that there should be a fee of 2s. 6d. in each case, and altogether withdrawn the objectionable limit of the fee to one house and for thirty days. Objection had been made to the medical man being made liable to prove his certificate in a court of justice under a penalty of £5. But he would not be called on to do so more than once in a thousand cases. For years they had been giving certificates of death; and yet how seldom had they been brought into courts of justice about them. In the course of his (Dr. Moore's) practice he had always notified infectious disease to the sanitary authorities, and that course on his part had always met with the approval of the heads of families. Mr. Gray's Bill had received the earnest support of the sixty members of the Corporation, who were all heads of families. If all medical men were bound to notify by an Act of Parliament, they would be all in the same position as regards the public. It might tell hardly on individuals, but sacrifices must be made for the public weal, and if they arrested the ravages of epidemic disease they would have done a great work. The system of notification by medical men had been established in England and Scotland, and however medical men here might shut their eyes to the fact, there was a cry for it on the part of the public which would surely be answered. They should take care that that cry was not

answered against the views of the profession. It was better for them to make a compromise with the leaders of public opinion. There was a golden opportunity for doing that now. Mr. Gray had shown an enlightened spirit in accepting some important amendments. Mr. Meldon had some important amendments on the books of the house on the part of the Dublin Sanitary Association. The King and Queen's College of Physicians also had supported the proposal to send the Bill to a select committee.

The President of the College of Surgeons (Dr. M'CLINTOCK) said he entirely concurred in the amendment, and in the views expressed by Dr. Moore. It was a great mistake on the part of the Association and the profession to put themselves in a position antagonistic to a measure which was incontestably calculated to render important and essential public service (hear, hear), and from mere regard for personal interest and convenience to place themselves in the position of obstructives of the Bill. He objected to some of the details of Mr. Gray's Bill as strongly as anyone, but that was no reason why they should knock over the whole coach. The public had not said anywhere that the notification of infectious diseases by their medical attendants would be a breach of the confidential relations between them.

Dr. DARBY did not see why medical men should be forced by Act of Parliament to violate the relations between themselves and their patients. He believed that the sanitarians of the present day were running a rig.

Dr. JACOB opposed the amendment. He did not think gentlemen were aware of the provisions of the Bill. The district in which a gentleman practised might be placed under the operation of the Bill by the board of guardians at any moment. Where the medical man diagnosed an infectious disease one course was to serve a notification of it on the head of the family, which was the most pleasing why. The other alternative was, with or without the consent of the head of the family, to send the document itself to the sanitary authority. If the former course were adopted, the custodian of the patient was bound to report the matter to the clerk of the union. Then the sanitary authorities were to go to the premises and see if they were disinfected; and if necessary they could cart away the patient to hospital, and do a variety of other things which no one could say would be grateful to the patient or the people in charge of him. If these things were not done, the custodian of the patient could be summoned to the police court, and the physician would have to give evidence against his own patient. He entirely protested against medical men being put in such a position, even if it were to get £1 instead of 2s. 6d. Calculating that there were about 114,000 cases of zymotic diseases in the country in a year, the remuneration to each member of the profession for notifying them would be about 28s. a year. A medical man who proclaimed a case of scarlatina in a school would be likely to get his *conge*. He (Dr. Jacob) did not say that there was a man to be found in the profession who would be so dishonest as to say what was really a case of scarlatina was not scarlatina; but if there were, the effect of this Bill would be to give a large practice at the expense of more honest people. The profession in England were averse to the system of notification by medical men. The Committee of the Association had rejected the proposal to refer the matter to a select committee because they felt that with the precedent against them of

seventeen English towns in which the system existed, and with the little knowledge of Irish medical affairs which most English and Scotch legislators possessed, the verdict of such Committee would be almost certainly against the profession. Amendments had been drafted by the Council of the Association and sent to Mr. Gray, and he was offered the Parliamentary support of the Association if he accepted them. He answered the letter in such a way that it did not reach the Committee of the Association until the evening when the Bill was down for Committee, so that the Executive of the Association were driven to the necessity of taking up a strong position. That position was a triumphant one so far. The whole profession was with them. Both the College of Surgeons and the College of Physicians had decided in their favour. The profession in Dublin had declared two to one against the Bill. He himself, on behalf of the *Medical Press*, had sent circulars to every medical man in Ireland; and he had already received forty-seven replies, not one of which approved of notification by the physician. The Bill was now *in articulo mortis*. If the profession budged from their position, it would be made law. There was no analogy between England and Ireland in the matter. The people of the latter country did not in general understand sanitary matters. What he contended for was that the responsibility of reporting a case of infectious disease lay upon the occupant of the house in which it occurred; just in the same way as the responsibility of reporting pleuro-pneumonia lay upon the owner of the animal that got it.

Dr. TAGGART thought it was the head of the family who should report, but that the medical man should inform him of the nature of the disease; and the medical man should be at liberty to report according to his discretion to the sanitary authority; but without being compelled to do so under a penalty. He could not swallow Mr. Gray's Bill. It was disgusting and nauseous to him, but he did not go the length of thinking with Dr. Jacob that medical men, if forced to report, would lose their patients.

Dr. CAMERON could not understand how Dr. Jacob took up the strong opposition he had in regard to this matter, for, on carefully listening to his observations that day, and reading the articles he had published in his journal, it appeared to him (Dr. Cameron) that he was a one-sided advocate. He spoke entirely on behalf of the medical profession, while at the same time he tried to show that if the medical men did as he suggested they would act for the public at large. Dr. Jacob said that the public would object to medical men giving information of disease being in a house, and in that way that the medical men would be placed in an invidious position and lose their patients. It appeared to him (Dr. Cameron) that there were only two classes of the general public they had to deal with in this matter. First, those persons who had comfortable houses in which the patients could be nursed at home; and, secondly, persons occupying tenement and humble cabins in country places. With regard to the first class he was satisfied from his lengthened experience that the householder was anxious of the earliest notification to the public authorities. When that intimation was given the public authorities could not interfere further than expressing their willingness to disinfect either the house or the clothes of the patient. The patient himself could not be taken away to hospital, as the parents would have the means of nursing him. On the other hand, when a medical man was called upon to attend a case in a tenement house, was it not to be considered what the medical man owed to the Commonwealth at large, and not his own narrow profession, and the responsibility he would incur if he did not at once notify to the public health authority the existence of a disease which would spread from family to family. If the notification was only made to heads of families, and to be by them reported to the authorities, he knew from experience it would not be made by the parents, or if it were it would be so tardy as to be productive of no good at all. He thought that it would appear to the public that the position medical men took up in this matter had a selfish aspect, and that was an impression they should guard against getting abroad. If notification was of use at all it should be the clear object of the medical profession, regardless of themselves entirely, that the notification should be as efficacious as possible.

Dr. QUINLAN said he was, he believed, the first medical man in this city to object to this proposal; and on the occasion, about sixteen months ago, when it was introduced to the notice of the Dublin Branch of the British Medical Association by his friend Dr. John William Moore, he was the

only person present who protested against it as a breach of professional confidence between the physician and his patient. Since that time he had carefully considered all that had been published and said upon the subject, and did not now see any reason to alter his opinion that the physician should not be the direct or even the indirect informant; and he believed that such was now the feeling of the vast majority of the profession. If such notification by the medical attendant to the sanitary authority is to be the rule of the future he did not see why the advocates of the system should confine it to purely infectious diseases; in fact, as an attentive student of pathology, he very much doubted if there be any real difference between infection and contagion. In the one case the germs reach the infected person by direct contact, and in the other by being breathed or otherwise wafted on the patient; and as both, therefore, are simple modifications of touch, he preferred the term of Dr. B. W. Richardson, of London, viz., "communicable diseases." He asked, therefore, why if one or more communicable diseases are to be notified to the sanitary authority to prevent their spreading among the public, all communicable diseases should not be so notified; and why, if the attending physician is to notify a case of measles or small-pox occurring to his private patient and regardless of that patient's wishes or interests, he should not be equally bound to notify a case of syphilis or of gonorrhoea. He had not the slightest doubt that if every case of venereal disease occurring in the whole country could be immediately notified and published to the world, the spread of such disease would be much diminished, and these maladies would ultimately and entirely be stamped out. This idea might appear startling, but it was after all merely the full extension of the notification plan. He hardly thought that the most advanced sanitarians were as yet ripe for compulsory venereal notification; but he had little doubt that, if they should carry their present proposal, they would soon become educated to the venereal one. Equally certain was he that should the medical profession, unfortunately, allow themselves to be converted into a corps of sanitary detectives, at present of infectious, or in future of contagious diseases, private patients suffering from such maladies, and who desired for their own good reasons and interests to keep such troubles private, would seek non-medical aid and advice. To notification by the householder to the sanitary authority he did not object, provided that the medical attendant has nothing to say to it beyond informing the head of the family, as he always does at present, of the nature of the disease and of its infective character. If Parliament in its wisdom should decide that such head of the family should then notify to the sanitary authority, it would be a matter solely between the householder and the State, and one with which the medical profession would have nothing to do. To do or not to do was in the hands of the general public through their Parliamentary representatives; and, if they decided on doing it, they would simply be adding another to the many compulsory acts, many of them disagreeable enough, which are incumbent on every citizen. For the general community, however, to ask a professional body to commit a breach of professional propriety would be a different matter; he did not believe, however, that the general community had any such desire. It was his opinion that the whole movement originated from a small but active body of sanitary enthusiasts who would push theoretical views to the most extreme lengths, and without due or, in fact, any consideration of their practical consequences.

Dr. STOKES said he had heard with deep regret the observations of Dr. Jacob. If his views should be generally adopted by the profession in Ireland, it would lead to their being placed in the painful and humiliating position of being compelled by the State to do that which they had now an opportunity of being foremost in aiding the State to do. It was inevitable that a law would be passed compelling the notification of infectious disease to be carried out by the medical man. There was no serious opposition to it in either England or Scotland. He had learned that gentlemen who at first opposed the system there were now foremost in assisting the medical officers of health to carry it out. Hardly a week passed that some centre in England did not apply to be put under the act there.

Dr. DAVYS approved of the principle of the bill, but certainly disapproved of putting another incubus on the medical officers by obliging them to notify to the local board the ailments of his patients. The heads of families were the proper parties to do so.

DR. MACNAGHTEN JONES (Cork) supported the attitude assumed by the council of the association towards the bill.

DR. CORLEY, alluding to the statements made about this being a breach of confidence between physician and patient, said he thought it would be a greater breach of confidence in many instances to notify the disease to the householder than it would be to the sanitary officer.

After some further discussion,

The Chairman then put the amendment, which was rejected by 23 votes to 11.

The report was then adopted.

DR. MARTIN (Portlaw) moved—

That this association reaffirms its approval of the principles enunciated by the council in reference to the Medical Act (1858) Amendment Bills now before Parliament; and declares its opinion that no alteration of the existing law can be satisfactory which does not provide for a sufficient degree of professional competency, guaranteed by a uniform curriculum of study and examination, as well as by similarity of fees, throughout the kingdom; and the association furthermore believes that no such reform could be effectively carried out unless the General Medical Council be reconstituted, and adequate provision be made for the representation of the profession at large in that body.

DR. MACNAGHTEN JONES seconded the resolution. There was no doubt that the general body of the profession was not represented on the Medical Council.

The resolution was agreed to.

DR. TAGGART moved—

That, inasmuch as the poor-law medical officers of Ireland are liable at all times to be called upon to perform public duties in priority to their business, however urgent, they are equitable entitled in respect to superannuation, as other paid servants. That this association approves of the terms of the bill now before Parliament to amend the law relating to superannuation, the present permissive system having failed to ensure justice to the medical officers being afforded, while, at the same time proving detrimental to the public interests.

He served as a poor law medical officer for thirty-six years, and at the end of that time was allowed to walk away without a shilling. Mr. Meldon, M.P., to whom they owed a great deal, had the matter in hand, and they trusted that he would bring it to a successful issue.

DR. CORLEY seconded the resolution.

DR. WALSH thought some of the funds of the disestablished church might be used to help out the superannuation of poor-law medical officers.

DR. BRODIE said he had been allowed a superannuation of £200 a year by the Limerick board of guardians; and in four or five other applications for superannuation they had done ample justice.

The resolution was agreed to.

DR. SMITH moved—

That the existing system under which medical relief tickets are granted operates most unjustly towards medical officers of dispensaries, and has been productive of gross abuses. That the indiscriminate granting of medical relief, at the public expense, to persons who can afford to pay for it imposes upon the ratepayers heavy expense, and upon the medical officer much unrequited labour, and at the same time tends to demoralise very many of the independent middle classes. That the council be requested to seek a legislative remedy for the abuse of the present system.

DR. SUPPLE seconded the above, which was agreed to.

DR. DARBY moved—

That this association reiterates its opinion that it is desirable that poor-law medical officers should be enabled to make provision for their widows and orphans; that the scheme proposed by the council is hereby approved, and that the council be requested to endeavour to cause it to be enacted.

DR. CARLETON seconded the resolution, which was agreed to.

DR. DAVID JACOB, of Maryborough, moved—

That this association is satisfied that the extension to Ireland of the English system of inspection of vaccination, and the granting of awards for excellence in results, is practicable and desirable, and would, in effect, prove highly advantageous to the public interest.

There was no doubt that inspection, such as existed in England, would be most useful. In England, however, there was a sum of £8,000 a year available for distribution, in

the shape of rewards for proficiency and success in vaccination.

DR. FLETCHER, of Ballinasloe, seconded the resolution which was agreed to.

The following officers and council for the ensuing year were elected:—

President—Dr. Banks, Dublin. Vice-Presidents—Leinster—Dr. Bellow Kelly, Drogheda. Ulster—Sir William Miller, Derry. Munster—Dr. Parsons Berry, Mallow. Connaught—Dr. H. O'Farrell, Boyle. Council—Drs. Boyce J. Wallace, Stillorgan; R. Browne, Rathmines; J. H. Chapman, Dublin; H. G. Croly, Dublin; Darby, Bray; Drapes, Ennisecorthy; Filson, Portaferry; R. Gray, Armagh; J. R. Harvey, Dublin; Hayes, Naas; A. H. Jacob, Dublin; David Jacob, Maryborough; Kidd, Dublin; Kinkead, Galway; James Martin, Portlaw; R. M'Donnell, Dublin; F. V. M'Dowell, Baltinglass; Molony, Tulla; G. Morrogh, Dublin; Nolan, Gort; C. Norman, Monaghan; Perceval, Stradbally; Pollock, Blackrock; George H. Porter, Dublin; T. Purcell, Dublin; J. Ridley, Tullamore; Sharkey, Ballinasloe; H. J. Smith, Donaghmore; Spencer, Dungloe; Tagert, Monkstown; W. Thompson, Dublin; Walshe, Kilmacthomas, Auditors—Dr. Albert Croly, Rathfarnham; Dr. H. Colpoys Tweedy.

On the motion of Dr. Wall, seconded by Dr. O'Kelly, thanks were voted to the professional and general press for their support of the fair claims of medical men and their reports of the proceedings of the association.

DR. DARBY was then called to the chair, and on the motion of DR. MALONEY seconded by Dr. Jacob, a vote of thanks was passed to the outgoing president, Dr. Chapman, with which the proceedings terminated.

THE DINNER.

The annual dinner of the Irish Medical Association was held on the same evening in the Albert Hall, Royal College of Surgeons. About sixty-five sat down dinner.

• DR. BANKS president of the association presided.

On the Chairman's right were—The Right Hon. the Lord Mayor, the Right Hon. W. E. Gibson, M.P., Mr. C. H. Meldon, M.P., Dr. Hayden, Mr. T. A. Purcell, Q.C., Dr. G. E. Duffey, Dr. Darby, Dr. Brodie, Dr. W. Thompson, Dr. Maloney, Dr. Nixon, Dr. Jacob, Dr. Little, Dr. Patton, Surgeon Ormsby, Dr. Browne, Dr. Minchin, Dr. Baker, jun. Dr. Davy, Dr. Martin, Dr. Croly, Rathfarnham.

On the left were—Sir George Owens, Dr. Chaplin, President of the Royal College of Surgeons, Dr. M'Clintock, Mr. M. Brooks, M.P., Dr. Croker King, Surgeon Porter, Dr. W. P. O'Brien, Dr. Nolan, Dr. Croly, Dr. Kidd, Dr. Quinlan, Dr. A. O. Speedy, Surgeon Hamilton, Dr. Pollock, Surgeon Preston, Dr. Chapman, Dr. O'Reilly, Surgeon—Major Speedy, Surgeon Daly, Dr. Ferguson, Dr. Carleton, Dr. Meldon, Dr. O'Kelly, Dr. Stack, Dr. Lawlor, &c.,

The proceedings were enlivened by music contributed by some talented amateurs.

The Chairman gave the usual loyal toasts, which were duly honoured.

The Chairman then proposed "The House of Lords and Commons." They expected the members of the House of Commons would support everything the profession thought right and proper, and they would oppose whatever the profession objected to, and there was a bill pending which the profession expected they would oppose, at least some clauses of it (applause).

The Right Hon. W. E. GIBSON, M.P., in responding, said the House of Lords had shown an earnest and anxious desire to consider from a broad and enlightened standpoint every measure calculated to promote anything connected with the learned professions. At present, owing to a variety of circumstances, the House of Commons was subjected to some peculiar criticism; it might be said, in many particulars, to be at present upon its trial. He could only say, for himself—and he was sure for his hon. friends who were there with them—that they could not but think that ultimately public opinion would arrive at the conclusion that notwithstanding all its faults, all its shortcomings, it would still retain the public opinion of the nation, and would be regarded throughout Europe as an assembly well worthy of admiration from all those who regarded deliberative assemblies (hear, hear). It was to them, during this very short Whitsuntide recess, a source of very great gratification to find themselves here in this assembly. It was, in the first place, most gratifying to find that they could have something of a change of face, of a change of associations, and of a change of topics. It was to

the last extent agreeable to himself, and he was sure to his hon. friends, to find that they could escape for a night from the Land Bill (laughter and applause), and to find that they could meet a very learned and distinguished profession, and find out, from close association and companionship, somewhat of their thoughts, somewhat of their opinions, and somewhat of their wishes. He knew for himself of nothing more gratifying than to find himself, as he had the honour that evening to be, the guest of a distinguished and great profession like the medical profession, and it was a comfort to reflect that, at all events, that profession, however its measures might, when introduced into Parliament, excite some differences of opinion, they were always regarded from a standpoint which was not one of politics. One measure had been referred to by the president which, he was told, was a subject involving some difference of opinion even in the medical profession, and who should decide when doctors disagreed (laughter). He understood that his hon. friend, the member for the city, had his name equally associated with this toast, and as his name was upon the back of this bill (laughter and applause), and as he understood he (Mr. Brooks) thought that in some quarter or other there was certain unanimity of sentiment about it, he (Mr. Gibson) would leave to him the discussion of that interesting question (laughter and applause). He could only say that any measure introduced, even by the Government, no matter what Government, after the Whitsuntide recess, had but a very sorry chance of success (laughter); and most unquestionably a measure which was not fathered by the Government, or—if he might say so, with great deference—by what he might call the responsible Opposition, but was introduced by a private member—if that was opposed by any private member with anything like resolution it had but a very uncertain hope of life. Should any opportunity in the vicinities of Parliamentary life occur for this measure coming under review, he hoped it would pass through committee with such amendments as would secure the legitimate self-respect of the medical profession (hear, hear); and, at all events, save from the ignominy of being asked to receive 1s. fees for doing anything (applause). He was not sure that they were likely to have for the rest of the session any other bill directly connected with the medical profession. He would be glad himself if he could see any chance of any other than the one bill being before the house for any considerable time. He believed that the great question of medical education and some of the more important questions connected with the medical profession which had been brought before the House of Commons during the last three years of the session, had now been sent to another tribunal, which he was sure, would investigate it with attention, with diligence, and with a conscientious determination to arrive at a wise conclusion. (Hear, hear.) The House of Commons, he thought, might very fairly suggest to the anxious medical student a grave topic for diligent and useful study. How it was, having regard to the anxiety and perplexities of political life, that members of the house managed to have any appearance of health, was a problem which, he thought, might well occupy the attention of anxious medical men. He had always heard since he was very young—he could not say that he was credited at any time of his life with being young—but still he had always heard that there were three things most essential to a thoroughly healthy life—dining at regular times, going to bed at a tolerably regular time, and having regular habits. He was bound to say that any man who looked to success in the House of Commons must learn how to dine at uncertain hours, must learn how to go to bed at all hours, and must acquire the habit of having grossly irregular habits. (Laughter.) And how was it that in place of these necessary conditions of health—how was it that they managed when they came among their friends and constituents they could not hope to be healthy (laughter)—but how they managed to simulate the appearance of health was one of the most startling questions that he thought could very well be submitted to any learned profession. (Laughter and applause.) He himself had often considered this position, and he could only tell them that he thought they managed to do it in a very extraordinary way, because members that worked the hardest hardly took any exercise at all, they had to dine out a good deal, an ordeal to which they submitted with a great deal of resignation (laughter), but at the same time it must be borne in mind that never under any circumstances whatever did members of the House of Commons take supper (laughter), and invariably, no matter how late they sat up, they walked home instead of driving home. He was not at all acquainted with medical science, and having given to them the conditions of the life of a member of Parliament, and stated how they

lived, he left them to consider how it was that his friend Mr. Brooks and his friend Mr. Meldon and himself looked so healthy. (Loud laughter and applause.)

Mr. M. BROOKS, M.P., in responding, said it was true that his name was on the back of a Bill which did propose, as he understood, to interfere with certain privileges of the medical profession, and some of the manners of controlling and regulating the public health. Well, he comforted himself with the knowledge that when doctors disagreed others might do the same. It had been pointed out to him that this was a subject upon which there was much difference of opinion, and he was bound to say that where there was a variety of opinions much allowance must be made for those whose duty it would be to prepare a proper and impartial and full inquiry before a select committee. He should always bear in mind it was his duty to do that. Nowhere could be found so just or so accurate an opinion upon this subject as the Irish Medical Association. (Hear, hear.) He should endeavour to follow in the footsteps of his right hon. and learned friend, the Attorney-General. (Laughter and applause.) He could assure them that in the British House of Commons—where Irish oratory and Irish patriotism were held in the highest regard—the eloquence of his right hon. and learned friend was greatly esteemed, and his right hon. friend kept alive the best traditions of the Irish representatives. (Applause.)

Mr. C. H. MELDON, Q.C., M.P., said he felt entirely overshadowed by the eloquence of his right hon. friend. He was, however, glad that his right hon. friend's speech had been productive already of good, for from the speech of his friend the member for Dublin, he saw that on a certain subject there did exist a difference of opinion. He thought that was an important omission, as the last time he heard Mr. Brooks speak on this speech he represented that the unanimity in Ireland was very considerable indeed. (Laughter.) Now, Mr. Brooks admitted that it was a subject suitable for discussion at all events, and so far he thought the speech of his right hon. friend had been successful. (Applause.) In the House of Commons they had been very much indebted to the medical profession for the last few years for giving them something to do. (Laughter.) From 1874 down to the present time the medical profession had treated the House of Commons with a great amount of confidence, for they had asked them to legislate for them on different points, and if the House of Commons had given them satisfaction it was quite sufficient recompense for the members of the house. (Applause.)

The CHAIRMAN next gave "The Army and Navy," which was responded to by Surgeon-Major Speedy and Surgeon-Major Preston.

The CHAIRMAN proposed "The College of Physicians," to which Dr. Hayden responded. "The College of Surgeons," to which Dr. Chaplin responded; and "The British Medical Association," to which Dr. Hayden responded.

Dr. CHAPLIN proposed "The Health of the Chairman," which was suitably acknowledged.

The CHAIRMAN then gave "The Guests," the Lord Mayor, Mr. Purcell, Q.C., and Dr. Croker King.

Other toasts were given, and the proceedings concluded at a late hour.

#### THE RE-VACCINATION FEE CASE.

##### OMAGH GUARDIANS.

MR. LAMMY inquired if any correspondence had come from the Local Government Board in reference to the above case. The Clerk replied in the negative.

A discussion occurred relative to the area of charge of the expenses attending the law suit.

Mr. Lammy said that, even though the law was that the Dispensary District should bear the cost, yet under all the circumstances of the case it would be more generous if the whole union would pay, as the question was one affecting the whole union, and indeed every union in Ireland.

Mr. Clements made some observation to the effect that the late small-pox scare, which was the origin of the whole case, had been encouraged in Fintona, and this would be a lesson to them in future, when they paid all the costs.

It was agreed to ask the Local Government Board if the expenses already incurred, and to be incurred in any further litigation could be charged to the union at large, as otherwise the Guardians would not feel justified in increasing the expenditure.

# IRISH POOR-LAW INTELLIGENCE.

## ROYAL MEDICAL BENEVOLENT FUND SOCIETY.

THE annual meeting of the Royal Medical Benevolent Fund Society of Ireland was held in the Royal College of Surgeons on Monday week last.

There was a very large attendance, including the Registrar-General, Rev. A. C. Thiselton, Drs. Patton, Cameron, Knipe, Wm. Thompson, hon. treasurer; Benson, hon. secretary; Marks, M'Clintock, President Royal College of Surgeons; Brunker, Tagert, Surgeon-Major Nash, Drs. Athill, A. H. Benson, Nolan, H. Kennedy, Duncan, Finny, Martin, James Brady, Morrogh, Bank, President I. M. A.; Maloney, Churchill, Barker, J. R. Kirkpatrick, Buchanan, Fitzpatrick, Darby, Chapman, ex-President I. A. M.; Hamilton, Surgeon Ormsby, Drs. Hawtrey, Benson, Brodie, Macnamara, Pope, Professor Moore, M. Eustace, Lynch, J. Eustace, Wharton, M'Cllelland, Gordon, Willes, Wheeler, Denham, O'Donovan, Montgomery, Cameron, Shannon, Story, Kidd, Jones, Duffey, Quinlan, J. W. Moore, J. R. Ferguson, Pollock, Smith, Jacob, Surgeon H. G. Croly, Drs. Minchin and Browne.

The chair was taken by DR. M'CLINTOCK, President of the Royal College of Surgeons, who, in opening the proceedings, said the object of this Society must commend itself to everyone. It was eminently Christian and charitable (hear, hear.) It was wholly unsectarian. Want and indigence, together with deserving character, were the claims to which they looked; and in its mode of operation the Society was conducted with the strictest regard to economy (hear, hear). He thought it should never be forgotten, and it deserved to be stated over and over again to the credit of the Society, that the names of these unfortunate brethren, or the widows or brethren, who are compelled by various circumstances and the exigencies of the occasion to seek help from the society, were never made public, (hear). This was not the rule with regard to kindred societies in England, where the names of the applicants and the details of each case were printed and circulated amongst the members. In Ireland they did not think the painful circumstances in which the applicants were placed should be made more painful by publishing them, (hear) and in that way they paid a proper and becoming regard to the feelings of the applicants, (hear).

DR. BENSON, honorary secretary, read the annual report, of which the following is an abstract:—

"The obituary list is this year unusually long, and contains the names of many old and trusty friends and liberal benefactors of the fund, amongst whom the committee may mention those of Dr. Albert Walsh, an original subscriber and a liberal donor, who for some time fulfilled the duties of honorary secretary, and was for many years an assiduous member of the Central Committee; of Dr. Alfred Hudson, who for more than

twenty years was a member of the Central Committee, and by the example of his munificent contributions, and also by his present influence, was a most valuable friend to the Society; of Dr. Christopher Fleming, for many years a subscriber, and member of the committee. Death too has deprived the Society of generous supporters in the widows of Dr. Charles Johnson and Surgeon James W. Cusack. But death is not the only enemy with which the committee has to contend. It has to contend with deplorable apathy amongst those from whom it should naturally expect the warmest sympathy, namely, the provincial medical men. The committee would, therefore, most strongly urge on such the importance of the work in which the society is engaged. Since its foundation in 1842 up to the present day, it has yearly relieved from the most urgent need many a brother practitioner who, from the pressure of adverse circumstances, has been driven to the verge of starvation. Within the past year one medical man has been granted the sum of £50 to assist him to emigrate. Another, who was found literally starving, has, by a grant of £25 been kept from entering the workhouse or dying of want. Owing to the disturbed state of the country, and the unsettled condition of property in general, and to the numerous foreign wars in which the United Kingdom has been engaged, the subscriptions during the last year show a falling-off both in the home and foreign list, whilst the same causes have tended to increase the number and indigence of those seeking aid from the society. The total amount of cash in the banker's hands to the credit of the Society on the 25th of May, the last day for making awards, was £1,143 16s. 7d. of which £110 10s. being donations, must be added to the society's funded capital, in accordance with the direct wish of the donors. Anticipatory grants to urgent cases have been given to the amount of £153. Of these claimants, three were medical men, and vouched to be in absolute distress. Your committee have now allocated further grants to the amount of £976, making the total amount of awards recommended since last report £1,129, of which £340 is to medical men, £691 to widows, and £98 to orphans. The number of central applications has diminished from forty-two to twenty-five, whilst that of the branches has increased from seventy-two to seventy-seven. The deaths of three beneficiaries of the fund has been reported to the committee, viz, that of a medical man who in three years received £240; that of a lady who in twenty-four years received £230 15s.; and one other lady who in four years received £29 from the fund. The desirability of forming branches in other British possessions, besides India is a subject which deserves the consideration of every friend of the society. A very large proportion of the medical men in all the public services, both at home and in the Colonies, are Irishmen, and numbers of other Irish medical men

have settled in various parts of our vast Colonial Empire. The first annual distribution of money by the society took place in June 1848, six years after its foundation; and consisted of £132 divided amongst sixteen widows. Since then, year by year, the Society has laboured, and not in vain, to relieve the most deserving applicants, so far as its funds would admit, and so much has the Society increased, that since then they have actually distributed the sum of £25,300, to which, if we add the sum allocated this year, makes the magnificent total of £26,429."

DR. WM. THOMPSON, (hon. treasurer,) submitted the balance sheet, and, in doing so, mentioned that of the 2,265 medical men in Ireland about one fourth subscribed to the funds of that Society. Spreading the income of the Society over the whole of the medical men of the country, it gave an average contribution of 5s. 1½d. per head; but really the income was subscribed by something less than a fourth of the whole number.

DR. MARTIN moved the adoption of the report and financial statement, and that 1,750 copies of the same be printed for circulation. He said it had been his happy lot to obtain from her gracious Majesty permission to place the word "Royal" before the title of the Society, and he could assure them that the queen was not in the habit of doing such a thing without due thought and consideration (hear hear). When the matter was placed before her and the Prince Consort nothing struck them more forcibly than the small expense at which the considerable amount of the funds of the Society was distributed (hear, hear). Her Majesty gave this as one of the reasons for promptly giving the title of "Royal" to the Society, and her gracious gift of £100 (hear, hear). Those who looked at the accounts would see that the same principles of economy still existed, owing to the unceasing care and watchfulness of the officers of the Society (hear, hear).

DR. MOLONY seconded the resolution, and expressed his satisfaction that the Society had not adopted the suggestion thrown out at the last meeting of appropriating large sums of the donations to the general purposes of the Society. In all cases he believed the wishes of the donors should be religiously respected (hear, hear).

The motion was adopted.

The REGISTRAR GENERAL (Dr. Grimshaw) moved, "That this meeting desires to convey its warmest thanks to the committee and officers of the parent Society, as well as to those of the provincial and Indian branches, for their hearty zeal in the society's beneficent work, and also to the student brethren, who have contributed a tangible proof of their generous sympathy in the cause." He thought that was a favourable opportunity, while thanking the provincial officials, to ask them to do a little more in whipping up the medical men throughout the country who did not subscribe to the Society.

DR. HENRY KENNEDY seconded the motion.

DR. STEELE said he might mention that one-third of the medical men who graduated in Ireland settled in England, and if there were any way of reaching them he was sure the society would be largely benefited by it (hear, hear).

The CAIRMAN concurred with Dr. Steele, and said what struck him was, that those men who settled in England were, nearly one and all, successful in practice (hear, hear).

The motion was passed.

DR. NOLAN, of Gort, moved—

"The disturbed state of the resources of the country having imposed much additional privation and embarrassment upon our necessitous brethren and their families, the committee feel it their duty to urge strongly upon the profession, and especially upon the poor-law medical members of it, that even a moderate annual contribution to this fund would enable it to assist more adequately the numerous cases of sore want and

misery which seek its aid, and which the committee, with the means at their command, can only relieve in a very stinted manner."

DR. DUFFY seconded the motion, which was adopted.

Professor MACNAUGHTEN JONES (Cork), moved the appointment of the committee and officers for the ensuing year, and referred with regret to the losses the society had sustained by the death of Dr. Albert Walsh, Dr. Alfred Hudson, and Dr. Christopher Fleming.

DR. PATTON seconded the motion which was passed.

A vote of thanks having been passed to the Press,

DR. DARBY was called to the second chair, and a cordial vote of thanks was passed to Dr. M'Clintock. In returning thanks Dr. M'Clintock mentioned that telegrams expressing regret at their inability to be present had been received from Dr. Wilberforce Arnold, President, and Mr. Browne, hon. treasurer of the Belfast branch of the Society.

The proceedings then terminated.

## IRISH MEDICAL ASSOCIATION.

### ANNUAL GENERAL MEETING, 8th June, 1881.

Report of Council for the Year, ending 31st May, 1881.

(Continued from page 40.)

#### PROVISION FOR WIDOWS AND ORPHANS.

In accordance with the terms of a resolution adopted at the last annual general meeting, your Council have to report that earnest attention has been given to the subject of providing annuities for the widows and orphans of Poor-law medical officers, resulting in the drafting of a scheme which proposes that all new entrants into the Poor-law medical service under the age of forty years shall be obliged to contribute a small annual payment to a fund from which an annuity to each widow and orphan shall be payable, with an optional power to those at present holding office to become contributors to the fund on certain conditions; and your Council beg to submit, as the outcome of their deliberations, the Draft Bill, which is printed to-day in another part of our issue.

A deputation from your Council recently waited upon the Local Government Board, and submitted the above measure, which for convenience was drawn up in the form of a Bill in Parliament—the form it must necessarily assume before it becomes law. The deputation was most courteously and kindly received by the Local Government Board, who, having made some valuable suggestions, expressed approval of the principle of the scheme, and a desire to co-operate with the Association and assist in an endeavour to secure the passing of a satisfactory measure which would enable provision to be made for the widows and orphans of Poor-law medical officers.

#### PETITIONS TO PARLIAMENT.

The following petitions to the House of Commons have been forwarded, viz:—

A petition in favour of Medical Reform.

A petition praying for extension to Ireland of the English system of awards for excellence in vaccination.

A petition praying that the medical officers of health may either be equitably remunerated for their services, or be relieved from compulsory acceptance of the position.

#### MEDICAL OFFICERS OF HEALTH.

Having failed to obtain from the authorities any recognition of the amendment made in the law by the passing of the Public Health Act of 1878 in favour of the Medical Officers of Health, whereby the maximal scale of salaries was expunged—an amendment made at the instance of this Association, and solely on account

of which the new Act was allowed to pass—a deputation from your Council, supported by Mr. Meldon, M.P., waited upon the Right Hon. W. E. Forster, Chief Secretary for Ireland, on the 1st November, and represented to him the unsatisfactory state of the administration of that Act as the natural result of the unjust treatment of the Medical Officers of Health, who have not even yet been awarded equitable salaries.

A report of the interview was published in the Report for half-year ending last December, as also the Memorial to the Lords Commissioners of Her Majesty's Treasury, which, at the suggestion of the Chief Secretary, was sent on the 22nd of November last, but no reply has been received except an intimation, in reply to a further letter, that the memorial had been sent for consideration to the Irish Government, who had not replied. Your Council thereupon addressed His Excellency the Lord Lieutenant, inquiring if any decision had been arrived at relative to the prayer of the memorial, but as yet they have received no reply, though several months have since elapsed.

#### FEEs FOR RE-VACCINATION.

A Dispensary Medical Officer of the Omagh Union having, in accordance with his duty, sent to the Board of Guardians his account for successful vaccinations and re-vaccinations which was duly certified for payment by his Dispensary Committee, was surprised to find that the Guardians questioned their liability to pay for cases of re-vaccination unless certified to have been successful, and that the Guardians, upon appealing, were advised by the Local Government Board to the effect that re-vaccination should not be paid for unless certified to be successful.

Small-pox broke out in the neighbourhood adjoining the said Dispensary Medical Officer's District, and in a most praiseworthy manner he promptly took active measures to protect, as far as he could, the inhabitants of his district by re-vaccination; consequently, an unusually large number of re-vaccinations was performed. But instead of his meritorious zeal being commended by the Guardians, who, as the Sanitary Authority of the District, are the guardians also of its public health, they refused to pay his bare legal claims.

The subject then came under the notice of your Council, who entertaining no doubt whatever as to the legality of the demand, directed proceedings to be taken against the guardians, at the expense of this Association, and after many legal formalities had been gone through the Court of Queen's Bench lately delivered judgment establishing the legality of the claim.

The following extract from a circular issued by the Poor Law Commission (now the Local Government Board for Ireland) puts the case of this Association with regard to this matter so forcibly and clearly that your Council desires to reproduce it for the information of the dispensary medical officers. At the same time they cannot refrain from expressing great surprise at the course taken by the Guardians, and the advice given by the Local Government Board with regard to it, viz:—

*“Extract from Circular on Small-pox—re-vaccination.*

*“No. 50, M/71—Miscellaneous.*

POOR-LAW COMMISSION OFFICE,  
Dublin, 2nd March, 1871.

3rd paragraph, *verbatim*.—“In their last circular the Commissioners recommended re-vaccination after an interval of about ten years from the time of successful primary vaccination, as essential to thorough security from attack. Every dispensary medical officer is aware that he is bound to vaccinate every person who applies to him for that purpose whether previously vaccinated or not; but a question has arisen whether the payment allowed for each case of successful primary vaccination is payable for a case of re-vaccination in which no effect has been exhibited.”

4th paragraph, *verbatim*.—“In answer to many inquiries addressed to them on that point the Commissioners have stated, that the non-appearance of a vesicle in cases of this class is no criterion of success or non-success, if the operation has been properly performed; the result in the latter case showing satisfactorily that the former vaccination is still protective, and that the operation must be therefore considered to have been successful, and should be included as such by the medical officer in his report (Form H) to the guardians.”

The circular was addressed

“To the Clerk of each Union.”

The 6th section of “The Vaccination Amendment (Ireland) Act, 1879,” provides that “The Board of Guardians shall pay to every such medical officer for every person successfully vaccinated or every person re-vaccinated by him within his dispensary district, the sum of two shillings.” To the Council for the time being of this Association who drafted the Vaccination Amendment Bill, which became the Act of 1879, is due much credit for having so carefully worded the section as to leave no reasonable room for doubt as to the legality of payment for all cases of re-vaccination irrespective of result; and your Council desire again to remind the dispensary medical officers that it is not necessary that persons successfully vaccinated or persons re-vaccinated shall reside in the medical officer's district, but merely that the operation shall have been performed within his district, to entitle him to payment.

#### PRISON SURGEONS.

A Coroner who, on a former occasion, refused to pay a prison surgeon for his evidence as to the cause of death of an executed convict, again denied the legality of a similar claim made by the same surgeon, although, in the first instance, the question was argued before the Grand Jury who presented for the surgeon's fees which were paid (see report for quarter ended 21st April, 1879, p. 31 to 34).

Your Council have learned, with satisfaction, that the Grand Jury, having been informed of the facts of the new case, at once agreed to present for payment of the fee.

#### ASSESSMENT OF SUPERANNUATION ALLOWANCES.

A letter was forwarded to the Right Honourable the Chief Secretary for Ireland, asking whether the opinion of the Law Officers had been taken with regard to the question of Assessment of Superannuation Allowances of Dispensary Medical Officers, which had been brought under his notice by the deputation which waited upon him on the 1st of November last (see last report, pp. 11—15), but no reply has yet been received.

#### INCORPORATION OF THE ASSOCIATION.

Your Council have to report that the steps necessary to have the Association made an Incorporated Society are now being taken, instructions having been given to Mr. Clifford Lloyd, Solicitor to the Association, to make the necessary arrangements without delay, in accordance with the resolution of last annual general meeting. In a short time your Council expect that the oft-expressed desire of the Association on this subject will be an accomplished fact.

It may be well, now, to remind the members, lest they should be taken by surprise and not understand the movement, that certain legal formalities have to be gone through, one of which requires the Association to be nominally dissolved, while at the same time, being re-formed without any change of name or any period of non-existence; for this purpose it will be necessary that each member shall sign the roll when submitted to him. Your Council desire to make it clearly understood that one of the effects of incorporation will be to terminate the liability of any one member to be made responsible

for the debts, if any, of the Association; when the Association is incorporated no individual member can, at any time, be held liable for more than the sum of five shillings, beyond the amount of his annual subscription.

The advantages to be derived from having the Association incorporated have so frequently been brought under notice, that your Council see no necessity for recapitulating them on this occasion.

#### IMPROPER ASSUMPTION OF MEDICAL TITLES.

Your Council having become aware of two instances in which Medical Titles were improperly assumed by unqualified persons, directed that notice be sent to those gentlemen to desist, or they would be held liable for the penalties specified in the Medical Act.

#### CANCELING OF TICKETS AND RECOVERY OF FEES.

A case has recently come under the notice of your Council in which a Dispensary Medical Officer got cancelled an improperly issued ticket for dispensary Medical attendance at the patient's residence, and afterwards successfully used the patient for £1 19s. 11d. at Petty Sessions. The amount of the fee is thus explained: the medical officer was entitled to two guineas, but as a sum of two pounds is beyond the limit recoverable at Petty Sessions, he thought it would simplify matters to claim only the above mentioned amount.

#### MEMBERS.

During the year just ended forty-two new names have been added to the list of Members, and in the same period fourteen resignations was accepted.

#### DEFAULTERS.

Your Council have to submit, with this report, a list of defaulters whose subscriptions for two or more years still remain unpaid, and to whom very numerous applications have been made; and they regret to feel called upon to recommend this meeting to direct that all the names on the list now to be submitted be removed from the list of members of the Association in accordance with Rule V., due notice having been given to each of the defaulters that this course would be taken.

#### OBITUARY.

Your Council, with deep-felt sorrow, have to report the loss by death of eleven members during the past year, viz:—Drs. Abbot (Bray), J. Brady, jun. (Dublin), Elliott (Waterford), Faussett (Clontarf), Hegarty (Kinsale), Hudson (Dublin), Jencken (Kingstown), Morewood (Draperstown), Morrison (Dublin), O'Connell (Templemore), and Peele (Dublin).

The late Dr. Hudson, one of the most distinguished and able physicians of our time, was lately a Vice-President of this Association, as was also the much respected Dr. Elliott, of Waterford. Dr. Faussett was for many years a member of the Council, and Dr. Edward Peele, whose untimely death is deeply deplored, was one of the most zealous and active members of the Committee of Council.

#### LIST OF ENTRIES IN THE REGISTER OF THE BRANCH MEDICAL COUNCIL (IRELAND) FOR THE MONTH OF MAY, 1881.

MAY 2nd.—Browne, Augustus James Arthur; Browne Hall, Balla, co. Mayo; Lic. R. Coll. Surg. Irel. 1880, 3rd.—Sullivan, John Philip; Queen's College, Cork; Lic. R. Coll. Phys. Edin. 1881, Lic. R. Coll. Surg. Edin. 1881.  
4th.—Sproule, Hamilton Magennis; Merville, co. Donegal; M.B. 1881 and B.Ch. 1881 Univ. Dub.  
5th.—Mallagh, Alexander; Dromore, co. Down; Lic. R. Coll. Surg. Edin. 1881.

7th.—Yeates, Edward Tongue; Grangemount, Balbriggan, co. Dublin; Lic. R. Coll. Surg. Irel. 1873.

7th.—Williamson, Macnamara Morgan; 18 Crow Street, Dublin; Lic. R. Coll. Surg. Irel. 1881.

9th.—Cronyn, John George; 69 Marlboro' Road, Dublin; Lic. R. Coll. Surg. Irel. 1880, Lic. 1881 and Lic. Mid. 1881 K. Q. Coll. Phys. Irel.

10th.—Brady, John Joseph; British and African Steam Navigation Company's Service, Liverpool; Lic. R. Coll. Surg. Irel. 1881.

11th.—O'Carroll, Joseph, Francis; 78 Rathgar Road, co. Dublin; Lic. R. Coll. Surg. Irel. 1881.

12th.—Rynne, John; Brookville, Ennis, co. Clare; M.B. 1881 and B.Ch. 1881 Univ. Dub.

12th.—Ross, Alexander; Bessbrook, co. Armagh; Lic. Apoth. Hall, Dub. 1879, Lic. R. Coll. Surg. Irel. 1881.

13th.—Bullock, John George Wright; Drumcondra Terrace, Dublin; Lic. R. Coll. Surg. Irel. 1881.

14th.—Geary, Eugene Joseph; 12 Mulgrave Street, Cork; Lic. R. Coll. Phys. Edin. 1881, Lic. R. Coll. Surg. Edin. 1881.

17th.—Quirke, James; Wallslough, co. Kilkenny; Lic. 1881 and Lic. Mid. 1881 K. Q. Coll. Phys. Irel., Lic. R. Coll. Surg. Irel. 1881.

18th.—Jacobs, William Wall; Turf Lodge, Curragh Camp, co. Kildare; Lic. R. Coll. Surg. Irel. 1880, Lic. 1881 and Lic. Mid. 1881 K. Q. Coll. Phys. Irel.

19th.—Lynch, Francis John; Armagh; Lic. R. Coll. Surg. Irel. 1875.

20th.—Barrett, Charles Dillon; Carrick-on-Shannon, co. Leitrim; Lic. 1881 and Lic. Mid. 1881 K. Q. Coll. Phys. Irel., Lic. R. Coll. Surg. Irel. 1881.

27th.—Henry, Thomas; Pomeoy, co. Tyrone; Lic. R. Coll. Surg. Edin. 1881, Lic. R. Coll. Phys. Edin. 1881.

#### MEMORANDUM.

The following names have been erased from the Register of the Branch Medical Council (Ireland) during the month of May, 1881, pursuant to the 14th Section of the Medical Act, no reply having been received to several letters of application, or as having been reported dead or ceased to practise, viz:—

Haines, Charles; Army Medical Department. Dead.

Blake, Walter Joseph; Army Medical Department. Dead.

Bernard, Michael Charles; Dundrum, co. Dublin. Dead.

Johnstone, John; Drumquin, Newtown Stewart. Dead.

Peppard, John; Piltown, co. Kilkenny. Dead.

Parker, Joseph; Limerick. Dead.

Warren, William Henry; P. and O. S. N. Company. Dead.

Bishop, Edward; Kinsale, co. Cork. Dead.

McMunn, Robert; Port Royal, Dromard. Dead.

Moylan, William Joseph; Army Medical Department. Dead.

#### VINEGAR ADULTERATION.

IN Glasgow recently, the Sheriff gave decision in a case under the Food and Drugs Act. The accused, one Lindsay, grocer and provision merchant, was charged with having sold to the sanitary inspector, a bottle of malt vinegar, which on analysis was found did not contain any of the constituents of malt vinegar, with the exception of 5.48 per cent. of glacial acetic acid, water, and a trace of saccharine matter. Sheriff Balfour, in passing sentence, said malt vinegar was asked for, but he held it was not malt vinegar that was sold. If he did not convict, the result would simply be that people would go on defying the Act of Parliament and deliver to parties asking for malt vinegar an article which was not malt vinegar. The mere fact of the practice having crept into the trade in Glasgow was certainly no reason why he should not convict in this case, but rather a reason that the practice, which was a bad one, should be put a stop to. His lordship then imposed a penalty of £1.
